The whole meeting was held at the new and modern building of the University of San Andres, actually the highest building of the country. There was also a scientific exhibit, which was much visited, not only by the delegates to the Congress but also by the local population.

The program also included formal invitations by the President of the Republic, by the Minister of Health and by the Mayor of the City of La Paz, the world's highest capital.

At the final session of the Congress, the subject of the next congress, to be held at Chicago in 1949, was brought up, and Dr. Palmer, the delegate of the American College of Surgeons, extended a cordial invitation to that meeting. Some Latin American delegates mentioned the question of the necessary funds and suggested that it would be extremely difficult for some of them to raise the necessary money to attend the next congress; Dr. Palmer offered to make a gift of the necessary amount, estimated as $30,000, from his own money, for delegates unable to attend the congress because of lack of funds. This offer was enthusiastically applauded, not only by the attending surgeons but also by the local press. On an invitation made by the Argentinian delegates, Dr. Palmer visited Buenos Aires after termination of the meetings.

## HAZARD OF LABORATORY INFECTION WITH LEPROSY

*To the Editor:*—In the Queries and Minor Notes section, THE JOURNAL, March 26, page 893, an inquirer who had pricked himself with a pin used in testing a leprosy patient for skin anesthesia, and who after an interval of twenty minutes had cauterized the site with sulfuric acid, asked whether or not he should take "a course" of one of the sulfones or some other drug as a prophylactic. If the lesion or lesions which had been tested with that pin were bacteriologically negative—by ordinary, standard methods of examination — the inquirer has no real cause for worry. If that examination was being made for the purpose of diagnosis, it follows in all probability that the simpler and more conclusive bacteriologic test had been made and had given negative results.

From the practical point of view, there would not be justification for serious worry on behalf of a healthy adult even if the lesions had been bacillus-positive lepromas instead of macular leprides. True, the evidence is almost beyond dispute that accidental infection can occur, and by just such means, but known instances are rare. Your referee mentioned the case reported by Marchoux, of Paris (*Internat. J. Leprosy* 2:1-6, 1934), in which an assistant at a biopsy was stabbed by a blunt needle and at once applied iodine vigorously, but ten years later had a leprous lesion at the place. Shortly before that de Langen, of Batavia, had reported at the Far Eastern Association of Tropical Medicine in Bangkok (1930) a case of apparent infection by a contaminated hypodermic needle (*Internat. J. Leprosy* 1:220-225, 1933). (The case of Lagoudaky's infection, claimed by him in at least three publications from 1936 to 1938 to have resulted from self inoculations, is not unequivocal, and anyhow it is of a very different category.) The most recent and interesting report of apparently accidental infection by the intradermal route is that of Porrit and Olsen (*Am. J. Path.* 23:805-811, 1947) of two American marines who were tattooed at the same time and in the same way by the same operator and who both had leprous lesions in the tattooed areas somewhat under three years later.

Such occurrences may seem to your inquirer as reason for real concern for his own welfare, but actually they can be regarded only as highly exceptional indications that infection of adult man by such means is possible. In their daily activities physicians, nurses and others who work with leprosy patients with infectious forms of the disease unavoidably have many intracutaneous and other introductions of bacilli without harm resulting, a point mentioned by your referee. More than once through the years I have seen colleagues strip off their gloves to treat with iodine accidental injuries incurred during operations, and more than once I myself have had occasion to do that at the autopsy table, but none of the persons concerned has ever shown any evidence of infection. Adult resistance being what it is, extremely few of the personnel of leprosy institutions have ever acquired the disease—and those who have done so have thereby laid themselves open to suspicion of gross and habitual carelessness.

As for prophylactic treatment of a person pricked with an infected needle, I can see no indication whatever that any known drug would be of the least benefit in that way. Years ago there was some discussion whether or not prophylactic treatment (with chaulmoogra derivatives) should be given to contact children, but of the few workers who tried that measure there were those who concluded that the disturbance of such treatment was more likely to be harmful than beneficial. The sulfones, it may be argued, have changed the situation. They certainly have proved to be exceptionally valuable in arresting the progression of the disease in active cases, and in many cases of lepromatous leprosy they cause more or less marked retrogression of conspicuous, bacillus-rich lesions; but that effect often stops far short of actual resolution of such lesions, and apparently the bacteriologically negative maculoanesthetic and tuberculoid lesions do not respond as well. Furthermore, as the lepromas retrogress their bacterial concentration does not decrease proportionately with the cellular elements, and bacilli may persist in the sites of lesions which have cleared up clinically. These facts would not encourage one to expect that the systemic administration of any known drug in any feasible dosage would eliminate, by bactericidal action, a few recently introduced bacilli; and to take any drug in sufficiently large dosage to maintain over periods of months or years a blood level that might be bacteriostatic, to meet so slight a chance of trouble as exists in the case under discussion, would be utterly irrational.

Finally, your referee reechoes the belief that all will be made known after the leprosy bacillus has been grown in culture. When that is accomplished, how will it be proved? Many men have been honestly convinced that they have grown that germ, but none has been able to convince the world for lack of a laboratory animal in which a disease resembling human leprosy can be produced, for the proof which Koch was able to adduce with respect to the nature of his tubercle bacillus culture. With tuberculosis it is not the in vitro experiment with the culture which affords the final justification for applying a new drug to man, but the in vivo animal treatment experiment. If we could find a laboratory animal susceptible to infection by human leprosy, or some method of making any of the ordinary laboratory animals susceptible to that infection, such crucial treatment experiments could be carried out at once, for we already have available—and always have had—veritable mass cultures of the germ in the nodules of active human lepromatous leprosy.

H. W. WADE, M.D.
Culion Leper Colony, Philippines.

## ARTIFICIAL INSEMINATION

*To the Editor:*—While the indications for and against artificial insemination by the use of donor semen have been well discussed in many publications, few publications have stressed the necessity of careful donor selection. Recently it has come to my attention that young interns and medical students are being used for this purpose. That does not seem to be the proper procedure.

A donor should be selected who carries as many as possible of the physical attributes of the husband of the recipient; but also it seems advisable that the donor be an adult male who has demonstrated his ability, first of all, to produce normal children, and secondly, has the ability to maintain his position in society as a father and a husband; thirdly, one who has the ability to accept education, and, fourthly, one who is able to acclimate himself to his fellow men. These few requisites will then only be the beginning of a genetically acceptable process which should be the aim of any gynecologist who is using artificial insemination as part of his therapeutic regimen for infertility.

LOWELL F. BUSHNELL, M.D., Hollywood, Calif.

# Medical Examinations and Licensure

## COMING EXAMINATIONS AND MEETINGS

### NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: *Parts I and II.* Various Centers. Sept. 12-14. Exec. Sec., Mr. E. S. Elwood, 225 S. 15th St., Philadelphia 2.

### EXAMINING BOARDS IN SPECIALTIES

American Board of Anesthesiology, Inc. *Oral.* Denver, Oct. 16-20. Sec., Dr. Curtiss B. Hickcox, 745 Fifth Ave., New York 27.

American Board of Dermatology and Syphilology, Inc.: *Written.* Various Centers, Sept. 15. *Oral.* Cincinnati, Sept. 15. Sec., Dr. George M. Lewis, 66 East 66th St., New York 21.

American Board of Internal Medicine: *Written.* Oct. 17. Asst. Sec.-Treas. Dr. W. A. Werrell, 1 Main St., Madison 3, Wis.

American Board of Neurological Surgery: *Oral.* Chicago, June 3. Final date for filing applications is Jan. 1. Sec., Dr. W. J. German, 789 Howard Ave., New Haven.

American Board of Obstetrics and Gynecology, Inc. *Part I.* Various Centers. Feb. 3. Final date for filing application is Nov. 5. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh.

American Board of Ophthalmology: St. Louis, Oct. 15-19; Boston, December. Sec., Dr. S. J. Beach, 56 Ivie Rd., Cape Cottage, Maine.

American Board of Orthopaedic Surgery. *Part II*, New York City, Feb. 9-10. Final date for filing application for Part II is Aug. 15. Address: Sec.-Treas., Dr. Harold A. Sofield, Room 1856, 122 S. Michigan Ave., Chicago.

American Board of Otolaryngology: Chicago, Oct. 4-7. Sec., Dr. D. M. Lierle, University Hospitals, Iowa City.

American Board of Pathology: Chicago, Oct. 7-8. Final date for filing application is Sept. 1. Sec., Dr. Robert A. Moore, 507 Euclid Ave., St. Louis.

American Board of Pediatrics: *Oral.* Cleveland, Sept. 16-18; New York City, Oct. 21-23; Chicago, Dec. 9-11. Sec., Dr. John McK. Mitchell, 6 Cushman Road, Rosemont, Pa.

American Board of Plastic Surgery: Examinations are given in June and November of each year in the home town of applicants. Sec.-Treas., Dr. Louis T. Byars, 400 Metropolitan Bldg., St. Louis, Mo.

American Board of Preventive Medicine and Public Health: *Parts I and II.* New York, Oct. 22-24. Final date for filing application is July 22. Sec., Dr. Ernest L. Stebbins, 615 N. Wolfe St., Baltimore.

American Board of Psychiatry and Neurology, Inc. *Special Examination.* Chicago, Oct. 24-25. December, New York City. Final date for filing applications is Sept. 15. Sec., Dr. F. J. Braceland, 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Radiology: *Oral.* Cincinnati, Sept. 28-Oct. 2. Sec., Dr. B. R. Kirklin, 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Surgery: *Written.* Various Centers, October 26. Sec., Dr. J. Stewart Rodman, 225 S. 15th St., Philadelphia.

American Board of Urology: *Written.* December. *Oral and Clinical.* Chicago, Feb. 11-15. Final date for receipt of case histories is Sept. 1, 1949. Sec., Dr. Harry Culver, 7935 Sunnyside Road, Minneapolis 18.

### BOARDS OF MEDICAL EXAMINERS

Alaska: * Juneau, Sept. 6. Sec., Dr. W. M. Whitehead, Box 140, Juneau.

Alabama: *Examination.* Montgomery, June 27-29. Sec., Dr. D. G. Gill, 519 Dexter Avenue, Montgomery.

Arkansas: * *Examination.* Little Rock, Nov. 3-4. Sec., Dr. Joe Verser, Harrisburg. *Eclectic.* Little Rock, Nov. 3. Sec., Dr. Clarence H. Young, 1415 Main St., Little Rock.

District of Columbia: * *Examination.* Washington, Nov. 14-15. Sec., Dr. G. C. Ruhland, 4130 E. Municipal Bldg., Washington.

Georgia: *Examination.* Atlanta, Oct. 11-12. *Reciprocity.* Atlanta, Oct. 13. Sec., Mr. R. C. Coleman, 111 State Capitol, Atlanta 3.

Guam: *Endorsement.* Agana, Last Friday of each month. Sec., Capt. C. K. Youngkin, Dept. of Public Health, Guam, % F.P.O., San Francisco.

Illinois: Chicago, Oct. 4-6. Supt. of Registration, Mr. Fred W. Ruegg, Capitol Bldg., Springfield.

Indiana: *Examination.* Indianapolis, June. Sec., Dr. Paul R. Tindall, 1138 K. of P. Bldg., Indianapolis.

Iowa: *Examination.* Des Moines, Dec. 5-7. *Reciprocity.* Des Moines, Sept. 5, Oct. 3, Nov. 7, Dec. 5. Sec., Dr. M. A. Royal, 506 Fleming Bldg., Des Moines.

Kansas: Topeka, Dec. 8-9. Sec., Dr. J. F. Hassig, 905 N. Seventh St., Kansas City.

Maryland: *Examination.* Baltimore, Dec. 13-16. Sec., Dr. Lewis P. Gundry, 1215 Cathedral St., Baltimore 1. *Homeopathic. Examination.* Baltimore, Dec. 13-14. Sec., Dr. John A. Evans, 612 West 40th St., Baltimore.

Minnesota: * Oct. 18-19. Sec., Dr. Julian F. Du Bois, 230 Lowry Medical Arts Bldg., St. Paul 2.

Mississippi: *Reciprocity.* Jackson, December. Sec., Dr. Felix J. Underwood, State Board of Health, Jackson 113.

Montana: Helena, Oct. 3-5. Sec., Dr. Otto G. Klein, First National Bank Bldg., Helena.

Nevada: Carson City, Nov. 7. Sec., Dr. George H. Ross, 112 N. Curry St., Carson City.

New Hampshire: Concord, Sept. 8-9. Sec., Dr. J. S. Wheeler, 107 State House, Concord.

New Jersey: Oct. 18-21. Sec., Dr. E. S. Hallinger, 28 W. State St., Trenton.

New Mexico: * Santa Fe. Oct. 10-11. Sec., Dr. Charles J. McGoey, Coronado Bldg., Santa Fe.

New York: *Examination.* New York, Albany, Syracuse and Buffalo, Oct. 4-7. Sec., Dr. Jacob L. Lochner Jr., 23 S. Pearl St., Albany 7.

Ohio: *Examination.* Columbus, December. *Endorsement.* Aug. 2 and Oct. 2. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

Puerto Rico: San Juan, Sept. 6-10. Sec., Dr. Luis Cueto Coll, Box 3717, Santurce.

South Carolina: *Examination.* Columbia, Nov. 8-9. *Reciprocity.* First Monday of every month. Sec., Dr. N. B. Heyward, 1329 Blanding St., Columbia.

Tennessee: *Examination.* Memphis, Sept. 28-29. Sec., Dr. H. W. Qualls, 1635 Exchange Bldg., Memphis 3.

Virginia: *Examination.* Richmond, Dec. 2-3. *Reciprocity.* Richmond, Dec. 1. Sec., Dr. K. D. Graves, 631 First St., S.W., Roanoke.

Wisconsin: * *Examination.* Madison, Jan. 10-12. Sec., Dr. C. A. Dawson, River Falls.

Wyoming: Cheyenne, Oct. 3. Sec., Dr. Franklin D. Yoder, Capitol Bldg., Cheyenne.

---

* Basic Science Certificate required.

### BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Alaska: Juneau, Aug. 28. Sec., Dr. C. Earl Albrecht, Box 1931, Juneau.

Arizona: *Examination.* Tucson, Sept. 20. Sec., Mr. Francis A. Roy, Science Hall, University of Arizona, Tucson.

Arkansas: *Examination.* Little Rock, Oct. 4. Sec., Mr. L. E. Gebauer, 1002 Donaghey Bldg., Little Rock.

Colorado: *Examination.* Denver, Sept. 14-15. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver 3.

District of Columbia: Washington, Oct. 24-25. Sec., Dr. G. C. Ruhland, 4130 E. Municipal Bldg., Washington.

Florida: *Examination.* Gainesville, Nov. 5. Sec., Mr. M. W. Emmel, University of Florida, Gainesville.

Michigan: *Examination.* Detroit and Ann Arbor, Oct. 14-15. Sec., Miss Eloise LeBeau, 101 N. Walnut St., Lansing 15.

Minnesota: *Examination.* Minneapolis, Oct. 4-5. Sec., Dr. Raymond N. Bieter, 105 Millard Hall, University of Minnesota, Minneapolis.

Nebraska: *Examination.* Omaha, Oct. 4-5. Director, Bureau of Examining Boards, Mr. Oscar F. Humble, Room 1009, State Capitol Bldg., Lincoln 9.

New Mexico: *Examination.* Santa Fe, Aug. 7. Sec., Miss Marguerite Kilkenny, 110 W. Houghton St., Santa Fe.

Oregon: Portland, Sept. 10 and Dec. 3. Sec., Mr. Charles D. Byrne, State Board of Higher Education, Eugene.

Rhode Island: *Examination.* Providence, Aug. 10. Administrator of Professional Regulation, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

South Dakota: Vermillion, Dec. 2-3. Sec., Dr. Gregg M. Evans, 310 E. 15th St., Yankton.

Wisconsin: Milwaukee, Sept. 24 and Dec 3. Sec., Prof. W. H. Barber, Ripon College, Ripon.

# Council on Medical Education and Hospitals

## CORRECTIONS

**Internships and Residencies.** The following services were inadvertently omitted from or incorrectly listed in the Internship and Residency Number of The Journal (May 14, 1949, pp. 161-225). These services are approved by the Council on Medical Education and Hospitals as indicated.

## MEDICAL ECONOMIC REVIEWS AND ABSTRACTS

### Prepared by the Staff of the Bureau of Medical Economic Research

*(Continued from page 1050)*

**Medical Payments Coverage.** By Ambrose Ryder. Casualty & Surety J. 9: 13-19 (May) 1948.

The introduction of third party medical payments coverage into third party legal liability policies has secured much good will for the casualty insurance companies, particularly in regard to automobile liability. Previously, the insured was protected against claims brought by injured parties, but he was unable to collect in the case of injuries to his own person or that of his wife, child or guest. The case of a lawsuit by a guest was particularly difficult since the insured became torn between his loyalty toward his friend and his obligation under his policy to cooperate with the insurance company in defense of all claims. The solution to these difficulties lay in a policy that would automatically pay for injuries to all passengers in the automobile. Since there already was a precedent for coverage of this nature in the "first aid" clause of the automobile liability policy, the automobile medical payment coverage evolved as an extension of the first aid coverage.

When the coverage was first announced by the National Bureau of Casualty Underwriters in 1939, two forms were approved; the first required the execution of a release. Both forms excluded operators from the benefits of coverage. Before long the release requirement was dropped entirely. The medical payments coverage is, therefore, a separate and distinct coverage without any tie-in with the third party legal liability coverage. The injured guests can receive the full benefits of the automobile medical payments coverage and yet bring claim against the insured for additional sums for which the insured person is fully protected under the bodily injury coverage. Since the insured was paying for the protection and since he often rode in his car as a passenger, the medical payments coverage was extended to include him and all other operators of the car.

The next step was to extend the medical payments coverage to cars other than private passenger cars, though the biggest demand for coverage is still from the private car owners. With coverage broadening in every direction, the only important exclusion today is on injuries received by an employee in the course of his employment and injuries sustained by a person eligible for payments under any workmen's compensation law. In general, the companies have broadly interpreted the scope of medical payments insurance relating to "entering upon, riding in or alighting from" the automobile. On the whole, the companies feel that the medical payments coverage has not only served as an instrument of good public relations, but also as a builder of premium volume of favorable loss ratio.

The medical payments coverage is now being extended to the field of general liability insurance. In contrast to the automobile liability policy, which insures all the occupants of the car, the general liability policy excludes benefits to the insured or any tenant of the premises, except domestic employees. Since medical payments coverage has been a feature of general liability insurance policies only since May 1947, it is too early to pass judgment on either its efficacy or its popularity.

**Medical Services in New Zealand.** By Hugh MacLean and Dean E. McHenry. Milbank Mem. Fund Q. 26: 148-181 (April) 1948.

The system of health benefits written into the Social Security Act of 1938 in New Zealand represents the most "advanced" experimentation in the field of state medicine among the free nations of the world. Before the advent of the Labor Government in 1935, there was little prepaid medical care in New Zealand. Although there were the friendly societies and fraternal orders, and although insurance funds were utilized in the payments for workmen's compensation cases, most practitioners were engaged in individual practice, collecting their fees from their patients.

While the method of providing the major medical services bore general similarity to those in the other English-speaking countries, a number of developments in the auxiliary health services were rather unusual. Extensive public health facilities had been established. A system of free dental services had been instituted in the schools. A program of infant feeding and of training of mothers, nurses, etc., known as the "Plunket movement," had reduced the infant mortality rate of the dominion to one of the world's lowest. Finally, the high standards of the medical schools in New Zealand have been an important determinant of the quality of medical care.

The Labor Party had promised the nationalization of medical services in its party platform. When the party took office late in 1935, it was announced that the Minister of Health, Mr. Peter Fraser, was considering a national health scheme and that a committee of House of Representative labor members under the chairmanship of Dr. D. G. McMillan was helping to formulate it. At this time the medical profession was poorly prepared to meet the popular and political demands for a national health program. "Although the British Medical Association, New Zealand Branch, . . . did establish a national health insurance committee, brought Sir Henry Brackenbury out from England to consult, and carried on a lively discussion of issues in its *Medical Journal,* the profession neither proposed a realistic, comprehensive scheme itself nor did it manage to maintain close contact with the Government while the provisions of the Social Security Act were being formulated."

The British Medical Association thought that the population should be divided into four groups with health services provided on the basis of their capacity to pay for services. The McMillan committee adamantly supported the principle of universal coverage and vigorously attacked the British Medical Association for classifying the people into income classes. The committee began its investigation by sending a questionnaire to ten groups that would be most affected by any health legislation. The committee does not present a clear statement of the replies to its questionnaire but incorporates in the committee report some of its own ideas. The report then recommends that a universal national health service be established. British Medical Association officials claim that they were not shown the report and that it was not published as a public document even after the Social Security Act was on the statute books.

On the motion of the Prime Minister, the National Health and Superannuation Committee was established. The report filed by this committee is, in effect, an approval of the security proposals Prime Minister Savage submitted to it. Half of the report is devoted to a rebuttal of the British Medical Association arguments. The other half is a recommendation to the House and to the Government of favorable consideration of the proposed legislation. Although the British Medical Association representatives had been assured that they would have the opportunity to examine the proposed bill before it went to the Cabinet and the House, the bill was sent through without being submitted to them.

In contrast to the schemes in operation in other countries which provide limited coverage only, the New Zealand bill anticipated universal coverage of the total resident population. The New Zealand plan was also unusual in that it was to be noncontributory, benefits being paid to all as a matter of right, regardless of whether or not taxes had been paid for the purpose. Funds to finance the entire social security program were to be raised by a flat tax on all income (originally 5 per cent, now 7½ per cent) and by an annual levy on all adults (1 pound for men and 5 shillings for women), which has since been repealed. Additional money to finance the program would be obtained from the Consolidated Fund of the state. New ground was broken in the comprehensiveness of the medical benefits to be provided. No other country, except perhaps Russia, ever afforded such complete protection.

The launching of the health program was a slow process. In April 1939, the first benefit, free treatment in state mental hospitals, went into effect. On May 15, 1939, the second class of benefits was made available. For an annual cost to the state of between 500,000 and 600,000 pounds, or around 6 shillings per capita, the financial burden of childbirth has been removed from the family and placed on the community. This class of benefits is easiest to administer, since an absolute check over the practitioner, patient and hospital exists in the form of birth records.

Hospital benefits for other than maternity cases became effective for inpatient treatment on July 1, 1939. (Outpatient treatment was included from March 1, 1947.) Charges on the social security fund for hospital services are larger than for any other class of health benefits. The total yearly cost to the fund has been over 2,000,000 pounds since 1943-1944. To this figure, 1,000,000 pounds which hospitals receive from local land taxes must be added to arrive at the total figure for hospital services. "Far from relieving Hospital Boards of financial burdens, it has added greatly to their responsibilities and their costs." This arises from the fact that the scheduled payment per patient per day does not pay the full cost of keeping a patient in a hospital, and the extra amount must be raised by the land tax. The hospital benefit has been a factor in filling hospitals to capacity and has necessitated the expansion of hospital facilities. "The charge is sometimes made that the availability of hospital benefits has caused a large number of chronic and minor cases to fill hospital beds, leaving a minimum of space available for cases in great need of hospitalization."

On March 1, 1941, physician benefits under the capitation scheme were introduced. The physician was to be remunerated from the fund at a fixed rate for every man, woman and child on his panel. There was to be free choice of physician by patient and of patient by physician. The British Medical Association was strongly opposed to the capitation system. The organization admitted that the costs of operation could be computed more accurately by the government and that administration would be comparatively simple. It contended, however, that an unfair burden of risk was placed on the practitioner, who must offer his services for a set amount per year regardless of the amount of illness encountered. Pressure from the profession has led to three major concessions: the fee for service plan, the right of the physician to charge the patient more than the fixed fee, and state refund to the patients rather than direct collection by the physician from the state fund. Although the Labor Party is still convinced that the capitation scheme is most satisfactory, its use has declined fairly steadily. Medical service for persons living in remote areas has been provided mainly through salaried officers. The salaries are necessarily high enough to attract young physicians into these areas.

In May 1941 a system of pharmaceutic benefits was inaugurated. The cost of these benefits has become increasingly higher. In 1945-1946 they cost almost as much as medical practitioner services. This tremendous cost is partly due to overprescribing by physicians. Better administrative procedures would eliminate abuses and reduce costs.

Roentgenologic diagnostic services were instituted in August 1941, massage services in September 1942 and district nursing services in September 1944.

The School Medical Service, which was established thirty-five years ago, has been greatly expanded since the Labor Government came to power in 1945. The National Dental Service, which is noted for its use of dental nurses to perform ordinary clinical operations, the comprehensiveness of its service coverage and its support by the dental profession, has also been greatly expanded.

Although the National Health Insurance Investigation Committee appointed in July 1936 held hearings throughout the country and collected the opinions of many interested persons, it cannot be regarded as an impartial and representative board of inquiry. The traditional type of Royal Commission, in this case composed of top representatives of the medical profession and outstanding experts from various fields, would have commanded much more respect than a departmental committee. The organized medical profession and the government have not been cooperating to the extent necessary for a proper functioning of the scheme. As the author of this article points out, "The Government must recognize that professional men and women are entitled to an important voice in determining the conditions under which they shall work. The profession must understand that the feature of universal coverage of health services is highly popular with the people, and that the doctors will lose in the long run if they adopt uncooperative attitudes.

"Finally, we think that the whole field of health benefits should be subjected to searching enquiry by a Royal Commission, headed by a chairman, recognized by the public as competent and impartial, and on which the medical profession should have representation. A thorough investigation is needed before further expansion of services, and might do much to bring the Government and the British Medical Association close enough to provide the basis for real cooperation . . ."

**Where Are We Going? Medicine in a Planned Economy.** By Frangcon Roberts. Brit. M. J. 1:485 (March 13) 1948.

This article, conditioned by current economic and medical problems in Britain, advances the often neglected fact that economic conditions of a country should limit the development of medical services. When invoked alone the spirit of humanitarianism, which is usually involved with emotionalism, would extend infinite medical care.

Citing the relative increase in the number of staff members in comparison to hospital beds, Dr. Roberts calls attention to the fact that the growth in medical care is not so much related to the increasing population or an increased incidence of disease, as it is to the rapidly increasing amount of medical care being given the patient in the normal course of treatment. For instance, in 1897 there was roughly 1 staff member to 10 hospital beds; now there is 1 to every 4½ beds. The use of laboratories and pathologic examinations in England is thirty-three times as great as in 1927. Despite this, the number of patients waiting for hospitalization is four times as great as it was ten years ago.

The author cites these facts among others as evidence of an "acceleration towards infinity" in the growth of medical care. What factors might occur that would limit this upward expansion? Dr. Roberts feels that stabilization of the population would invoke little change since, as already pointed out, most of the expansion in facilities for medical care has come from the increased amount of medical care given each patient in the normal course of treatment. Thirty-five years ago a small single x-ray installation was sufficient and "up-to-date." This is far from the extensive radiology equipment now available and "standard" in most hospitals today. Yet the nature of medical science implies that there are unobtainable goals.

Improvement in social conditions, the author believes, will aid little in retarding this "acceleration." There is little correlation between social conditions and the major diseases that are filling the hospitals today. Moreover, there is the extreme danger of the doctor's becoming involved in extensive litigation as the patients become more acquainted with various medical technics and demand their use for treatment, especially when these are provided "without cost" to the patient. This pressure will naturally contribute to the overuse of medical services. Furthermore, as the standard of living increases, nonessentials will creep into medical care and patients will come to judge efficiency by the number of "extras" offered. Dr. Roberts cites the "dainty teas" so favored by women patients at cottage hospitals "to which they should not have been sent" in the first place.

The advancement of science in reducing the need and expansion of resources for medical care is peculiarly susceptible to diminishing returns. All that medical care can do is to prolong life for a few years. Science has had its most obvious exploits in the cure of acute rather than chronic ailments. "Progress slows up as we come to deal with the weaknesses of the flesh." This is especially true because humanitarianism prevents scientific breeding and wholesale slaughter of the unfit—scientific approaches used by the agricultural and biologic scientist.

If none of the aforementioned factors is likely to restrict the "demand" for medical service, is it enough that humanitarianism should alone be the controlling factor in the allocation of medical care? Human life is not beyond price at all times. Obviously we could nearly eliminate deaths from automobile accidents by establishing a 10 mile per hour speed law. This we could do at the expense of causing radical changes in our commerce and curtailing our pleasure.

"While I fully appreciate that in practice the humanitarian and economic motive cannot be separated, I am convinced that we cannot solve the problems which confront us unless we realize that national prosperity determines the humanitarian component and is largely determined by the economic component. The importance of the economic component is brought home to us only when manpower is short. Always implicit in the work of the military medical services, it is forced upon us for the first time during peace by the stark reality of our plight. We must constantly bear in mind that every person engaged in medicine is a person lost to the production of food and exports. Medicine is now not only a humanitarian profession but also an indirectly productive trade."

At times Dr. Roberts' economics seem somewhat elementary and rather flavored with mercantilism, a view which is not unexpected in light of Britain's present drive to increase exports. Dr. Roberts has not intended this as a scholarly article on economics. Treated as comments by a physician regarding economic limits on the extension of medical care, his essay is extremely timely and stimulating—especially in its view that while economics is a "dismal science," those who think that medicine is above economic laws are destined to have their illusion rudely shattered, for a limited and planned economy obviously cannot support a health service expanding with the acceleration that medicine now exhibits."

**The Chicago Survey of Employees Benefit Plans (General Summary).** Research Council for Economic Security, 111 W. Jackson Boulevard, Chicago 1, 1948, 4 pp.

The council is conducting studies in certain metropolitan areas to determine what plans private employers have initiated to help employees meet crises inherent in their working in a specialized economy. This summary states the findings of this council on all types of firms in the Chicago metropolitan area—an area of about a 40 mile radius containing a labor force of about 3,500,000.

While their method of collecting the data, the mailed questionnaire, has certain inherent difficulties in producing representative data, as the Council recognizes, the summary reasonably concludes that at least 50.2 per cent of the workers in the Chicago area are covered by employer-maintained life insurance, 49.5 per cent are covered by employer-maintained prepaid hospitalization, 49 per cent are covered by pension and retirement plans, 40.3 per cent by cash sickness or paid sick leave, 34 per cent by organized cash sickness benefits and 29.3 per cent by prepaid surgical benefits. Other benefit plans were also reported. These figures are quoted as safe minimums for the Chicago area; actual figures are probably higher than this. "Preventive programs" such as organized recreation and industrial hygiene plans are also in considerable evidence.

A more satisfactory sampling technic might arrive at more precise figures. Of further interest would be data on the extent of the benefits offered under the various plans. The survey points out that "the results of this survey show a tremendous amount of protection against crises for workers." A similar study at a later date would certainly be of value in indicating the extent of the growth of such employee protection plans.

## MEDICOLEGAL ABSTRACTS

**Privileged Communications: Attorney's Right to Comment to Jury on Failure to Waive Privilege.**—The plaintiff filed suit for damages for personal injury sustained in an automobile accident. From a judgment in favor of the defendant, the plaintiff appealed to the Supreme Court of Iowa.

During the arguments to the jury, one of the defendant's counsel told the jury that a physician for the plaintiff was not called as a witness so that the jury did not have the benefit of his testimony and "that this jury—that counsel for the plaintiff as well as Mr. White—and myself know why he wasn't called." The plaintiff's attorney objected to such statements as being improper argument and prejudicial. Before the trial court ruled on the objection, another attorney for the defendant stated to the court, in the presence of the jury: "It is the contention that counsel for the plaintiff could and did come in with their objections and kept the doctor from testifying." The issue to be decided on this appeal, said the Supreme Court, is whether or not it is proper for counsel, in argument to the jury, to comment on the exercise by the opposing party of his right not to have his physician testify as to privileged matters.

The Iowa statute concerning the patient's privilege as to matters growing out of the relationship of physician and patient provides: ". . . no practicing . . . physician . . . who obtained such information by reason of his employment . . . shall be allowed, in giving testimony, to disclose any confidential communication properly entrusted to him in his professional capacity, and necessary and proper to enable him to discharge the functions of his office according to the usual course of practice. . . . Such prohibition shall not apply to cases where the party in whose favor the same is made waives the rights conferred." This, said the court, has been the statutory law of Iowa since 1851 and it should receive a liberal construction designed to carry out its manifest purpose to make consultation by the patient with his physician entirely confidential and free from anticipation or fear that this confidence will be broken by the examination of the physician as a witness in some legal proceeding.

There seems, however, to be a conflict in the authorities as to whether the exercise of the privilege by one party is a legitimate subject of comment by opposing counsel, continued the court. In one prior Iowa case the offered testimony of plaintiff's former lawyer was objected to by the plaintiff on the ground of privilege and the objection was sustained. The court instructed the jury not to "indulge in any speculation or suppositions concerning what any witness or witnesses might have testified to had they been permitted to testify." In approving this instruction, the Supreme Court of Iowa said: "The ordinary rule is that if one does not produce testimony within his control, or prevents the use of such testimony, the presumption arises that such testimony, if produced, would be adverse to them. But this rule does not apply to privileged communications for reasons too obvious to mention." And from another case: "A party should not be prejudiced by claiming a right which the law gives him."

Fidelity to our rule, that no unfavorable inference arises when a patient exercises his statutory privilege by not calling his doctor or objects to the other party introducing his doctor's testimony, concluded the Supreme Court, demands our adherence to the corrollary rule that opposing counsel, in such circumstances, will not be allowed to comment on such failure to produce the doctor as a witness, or the patient's objections to his testimony. The only purpose of the comment is to lead the jury to infer that the doctor's testimony, if allowed, would be unfavorable to the patient—the very inference condemned in our opinions in prior cases.

Accordingly the Supreme Court held that the conduct of the defendant's attorneys was improper and the judgment in favor of the defendant was reversed.—*Howard v. Porter, 35 N. W. (2d) 837 (Iowa, 1949).*

## AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1938 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Changing Concepts of X-Ray Pelvimetry. A. E. Colcher and W. Sussman.—p. 510.
Extraperitoneal Cesarean Section in Profoundly Infected Patient. M. L. McCall.—p. 520.
Review of 445 Pregnancies Complicated by Fibromyomas. D. J. Grandin.—p. 532.
*Anemia of Pregnancy Treated with Molybdenum-Iron Complex. W. J. Dieckmann and H. D. Priddle.—p. 541.
Time of Recurrence of Endometrial Carcinoma. H. Speert.—p. 547.
Method of Forceps Rotation in Posterior Positions. A. J. Tatelbaum.—p. 553.
New Concept in Replacement of Inverted Uterus and Report of 9 Cases. A. B. Johnson.—p. 557.

**Oliguria and Anuria in Toxemias of Pregnancy.**—Mauzy and Donnelly discuss the syndrome of decreased renal output associated with various types of toxemia of pregnancy. They cite 9 cases which came to their attention during the past five years. The incidence in their series of toxemia was 5 per cent with 1 death. The pathogenesis involves many factors, none of which acting alone seems to be responsible, but acting together render the tubular cells susceptible to injury by certain chemical substances. The authors are of the opinion that once oliguria or anuria develops the interruption of pregnancy is mandatory. In view of the tubular damage with leakage of the glomerular filtrate into the blood stream, excessive fluids will lead to cardiac decompensation and pulmonary edema with death; therefore, they must be restricted. Renal decapsulation may be a lifesaving procedure in some cases; in the authors' experience it was of questionable value. Peritoneal irrigation is a valuable procedure; serving as an artificial kidney, it removes the waste products during the period of tubular regeneration.

**Plasma Volume and Extravascular Fluid Volume During Pregnancy.**—Caton and associates investigated the changes that occur during normal pregnancy in the circulating red cell mass and plasma and extravascular fluid volumes. Simultaneous determinations of plasma volume and extravascular fluid volume were made. The plasma volume was found to be increased greatly during pregnancy and to reach maximum volume during the sixty-eighth to fifth day prior to the onset of labor. This increase was 49 per cent when compared with the nonpregnant values thirty days following delivery. Plasma volume had returned to normal nonpregnant values by the thirtieth day after delivery. There was an increase in the amount of extravascular fluid up to the onset of labor. The rate of increase was accelerated during the last trimester with no evidence of any prelabor decrease. In the first week of the puerperium there was a 2,500 cc. decrease in extravascular fluid volume. The extravascular fluid volume, when measured for the final time between the twenty-sixth and sixty-sixth day of the puerperium, was 59 per cent below the maximum prepartum value. The vascular and extravascular spaces show a retention of fluid which varies in amount in each trimester of pregnancy. The percentage increase of plasma volume during the first and second trimesters exceeds the percentage increase of extravascular fluid volume. In the last trimester, the percentage increase in extravascular fluid volume is greater than the percentage increase in plasma volume.

**Molybdenum-Iron Complex in Anemia of Pregnancy.**—Dieckmann and Priddle had gained the impression in earlier investigations that iron salts were of little value in anemia of pregnancy. Reports by Healy and Neary indicated that a molybdenum-iron complex was more efficacious. The authors resorted to treatment with this preparation in pregnant women in whom anemia had been detected by a special screening method in use at the Chicago Lying-in Hospital. Capsules containing 3.0 mg. of molybdenum sesquioxide (approximately 2.5 mg. molybdenum) and 195 mg. of ferrous sulfate (approximately 40 mg. iron) were given to these patients (2 capsules three times a day, after meals). They contained no significant amounts of copper. Complete blood studies had been made, and the hemoglobin determination, hematocrit reading and red blood cell count were repeated every two weeks. The authors found the molybdenum-iron complex very effective in causing significant increases in the hemoglobin concentration of most patients with anemia of pregnancy within a three-week period. If the hemoglobin does not show a significant increase in this period, further hematologic studies are indicated. The hematocrit determination is an easy, rapid and accurate method of determining anemia. It is more accurate than the hemoglobin concentration as it is usually determined. Pregnant patients should have a hematocrit determination every three months, one at or near term, and one also at six weeks post partum. If the hemoglobin is less than 12 Gm. (hematocrit 37 per cent) in the first twelve weeks or is not 12 Gm. or more six weeks post partum anemia is indicated. From the twelfth to the thirty-sixth week the lower limit of the hemoglobin in pregnancy is 10 Gm. (hematocrit 30 per cent) per hundred cubic centimeters. The lower limit from thirty-six weeks to term is 10.5 Gm. (hematocrit 32 per cent) per hundred cubic centimeter.

**Electroencephalography in Babies Born to Mothers Given Seconal Sodium.®**—Hughes and his associates present electroencephalographic observations on a group of newborn infants whose mothers were given varying doses of seconal sodium® (sodium 5-allyl-5-[1-methyl-butyl] barbiturate) during labor. All were normal infants born of women whose labors and deliveries were uneventful. A total of 51 electroencephalograms were obtained on 20 of these infants, tracings on 11 of whom were made during the first twenty-four hours of life. In comparison with electroencephalographic patterns previously found characteristic of normal, full term, sleeping infants, the brain waves of these babies showed a striking electrical cortical depression characterized by a pronounced decrease in slow waves of moderate amplitude and some increase in fast waves of low amplitude. The apparent effect of seconal sodium® in depressing the electrical activity of the baby's cortex persisted for three days in some infants, even when clinical signs of drowsiness had been overcome. This indicates that electroencephalography is a more sensitive index of cortical depression than mere clinical observation.

**Abnormal Electroencephalograms in the Newborn.**—Hughes and co-workers present data on 8 full term newborn infants whose electroencephalograms showed definite abnormalities. Seven of these infants showed clinical neurologic abnormality, while 1 of them was clinically normal. In several of the infants the pattern of neurologic disorder was correlated with localizing electroencephalographic abnormalities. In some infants the electroencephalogram demonstrated cortical electrical abnormality before clinical symptoms and signs had been observed, and electroencephalographic abnormalities persisted in some of the infants after neurologic symptoms had disappeared. Of special interest was the patient who showed electroencephalographic abnormalities while continuing to seem normal clinically. This indicates that electroencephalography of the newborn may detect cortical damage in the absence of clinical symptoms. The authors feel that by correlation of abnormal electroencephalographic findings with some of the factors at play in labor and delivery further refinements in obstetric management may be evolved.

Part Time Radiologic Practice in Hospitals of Small Cities. W. S. Peck.—p. 236.

**Roentgenology in Prognosis of Minimal Tuberculosis.**—Cochrane and associates report on the prognostic value of the roentgenologist's diagnoses: "active," "of questionable clinical significance," and "inactive, of no clinical significance." Eleven hundred cases of minimal tuberculosis, representing, with a few minor exceptions, all the cases of minimal tuberculosis diagnosed at the Henry Phipps Institute for the twenty years 1926 to 1945 have been classified and followed up. The authors analyzed the prognostic value of the roentgenologist's opinion of activity at the time of the first roentgenogram. Both progression rates and death rates indicate that such opinions are of great value in determining the type of treatment for such cases. The error of the roentgenologist has also been estimated by two different methods on the same roentgenograms. Both confirm the recently published opinion that there is a considerable roentgenologic error. The technic of comparison with the errors of a roentgenologist sorting roentgenograms blindly shows that the results are much better than those which would have been expected by chance; in particular, the error in the diagnosis of inactive minimal tuberculosis has been found to be small.

**Vertebral Angiography.**—Sugar and associates subjected a patient in whom a ruptured aneurysm was suspected to bilateral percutaneous carotid arteriography without demonstrating a lesion. The desire to study the vessels of the posterior fossa in the case led to the development of a successful technic of deliberate percutaneous vertebral angiography. The authors describe a new percutaneous technic for vertebral angiography, which they have used in over 20 cases, with good visualization in all but 2 early attempts. They describe normal vertebral-basilar angiograms and describe 5 cases with reproductions of vertebral angiograms showing the type of information which can be obtained. Two of these are cases of basilar aneurysms visualized for the first time ante mortem without operation. One shows collateral circulation of the entire cerebrum in a patient with traumatic carotid-cavernous fistula. One concerns a thalamic carcinomatous metastasis, and one describes a patient with posterior fossa arteriosclerosis. The authors review the historical development of vertebral angiography and make a survey of the recent publications on aneurysms of the posterior intracranial circulation. They discuss the indications and complications of vertebral angiography. The method is indicated in patients in whom air study fails to visualize the posterior part of the third ventricle, the aqueduct of Sylvius and the fourth ventricle. It would be even more useful in those in whom clinically indicated exploration of the posterior fossa fails to reveal a cause for the patient's symptoms. This holds especially for patients with seizures, who have otherwise signs and symptoms of posterior fossa neoplasm and in whom the lesion may well be at the tentorium. Alternatively, it may come to be preferred over air injections as a first diagnostic aid even though (at least in the hands of the authors) a general anesthetic is required. Angiography of either carotid or vertebral vessels seems to be readily tolerated in patients with increased intracranial pressure and does not carry with it the dangers of disturbing the ventricular equilibrium such as occurs in ventriculography; nor is it necessary to follow angiography with exploration.

Intent of American Venereal Disease Association. R. W. Barnes.—p. 187.

**"Biologic False" Reaction for Syphilis.**—Stokes and James examined records of patients who had been under extended observation for the interpretation of a positive serologic reaction for syphilis. Of 68 patients for whom a diagnosis of nonspecific positive reaction had been considered, 23 were eliminated because an ultimate diagnosis of syphilis was made. The authors emphasize the complicated and puzzling character of the biologic false or nonspecific positive serologic reaction for syphilis. It appears to be part of a general infection reaction mechanism shared by many diseases and forms of injury, more developed in some persons than in others. Febrile states, especially those due to infections, virus diseases, foreign protein inoculations and certain diseases, such as leprosy, malaria and infectious mononucleosis, are particularly apt to bring out biologic false positive reactions and reactors. There is reason to suspect that a seronegative status in a syphilitic person may be converted into a seropositive state by some of the agencies that can produce a biologic false positive state, and that syphilitic patients approaching serologic cure may be maintained for some time in a low titer fluctuation by a tendency toward biologic false positive reactions. The proportion of biologic false or nonspecific positive reactions in a series of routine positive reactions may approach 40 per cent of the positive reactions obtained in a run or survey. But the proportion of biologic false positive reactions in all tests and in serologic surveys probably does not exceed 1 in 700. An effort should be made to repeat every test in which the reaction is positive, to check the commoner possibilities of biologic false positive reaction at the time, as well as after, the test result is reported. Treatment should be withheld until the situation has been evaluated. The pregnant woman approaching term might be an exception. The temptation to use 10,000,000 units of penicillin as a short cut to a decision (accepting syphilis as the diagnosis) or "just in case" should be resisted. The decision to treat must be reached only after every possibility has been investigated.

**Penicillin in Early S[illegible]** [illegible] and co-workers examined the efficacy of [illegible] practiced by the Army in the treatment of early syphilis. The prescribed treatment of primary and secondary syphilis consisted of sixty consecutive intramuscular injections of 40,000 units of aqueous *amorphous penicillin* at three hour intervals for seven and one-half days, amounting to a total dose of 2,400,000 units. Evaluating the results obtained in 31,000 soldiers with early syphilis, the authors state that the incidence of failure was lowest in seronegative primary syphilis (87.3 per thousand patients of both racial groups), higher in seropositive primary syphilis (186.2 per thousand patients) and highest in secondary syphilis (282.7 per thousand patients). The total failure rate was 159.1 per thousand treated patients. The failure rate was consistently greater for Negro than for white patients. The total failure rate for white was 100.5 per thousand patients, against a failure rate of 227.0 per thousand Negro patients. It has been suggested that this difference reflects a higher incidence of reinfection among Negro patients. The authors gained the impression that some additional factors might be responsible for the higher failure rates among Negroes, since they found no significant differences in the distribution of white and Negro failures by type of failure. Patients treated during the latter half of 1945 had a failure rate of 239.4 per thousand patients, which was about 86 per cent greater than the failure rate of patients treated during the latter half of 1944. This has been attributed to a chemical change in amorphous penicillin consisting of an increase in the ineffective K species at the expense of the potent G species. This situation no longer prevails. Among the 5,600 patients for whom the results of cerebrospinal fluid examinations were available, only 3 doubtful and 21 abnormal spinal fluids were found, which is an incidence of about 4 abnormal spinal fluids per thousand persons examined. This seems to indicate a remarkable neurotropic effect of penicillin.

### American Journal of Tropical Medicine, Baltimore

**29:1-172 (Jan.) 1949. Partial Index**

Action of Antimalarial Drugs in Mosquitoes Infected with Plasmodium Falciparum. L. A. Terzian and A. B. Weathersby.—p. 19.
Malaria Reconnaissance of the State of Veracruz, Mexico. J. Bustos Castellanos, L. Cerdán Murrieta, G. Lassman and Carmen Ortiz. —p. 23.
*Synergistic Action of Penicillin and Streptomycin on Endameba Histolytica Cultures. H. Seneca, E. Henderson and Martha Harvey.—p. 37.
Purification of Hemoflagellate Cultures with Antibiotics. H. Seneca, E. Henderson and Martha Harvey.—p. 41.
Additional Observations on Trypanosoma Cruzi Chagas, from Arizona in Insects, Rodents, and Experimentally Infected Animals. S. F. Wood. —p. 43.
*Immunity to Yellow Fever Six Years after Vaccination. G. W. A. Dick and K. C. Smithburn.—p. 57.
Typhus Fever in Mexico: Study of Epidemiology by Means of Complement-Fixation. G. Freeman, G. Varela, H. Plotz and C. O. Mariotte. —p. 63.
Voluntary Infection with Schistosoma Haematobium. C. H. Barlow and H. E. Meleney.—p. 79.

**Synergistic Action of Penicillin and Streptomycin on Endameba Histolytica.**—Seneca and his co-workers found that neither penicillin nor streptomycin is amebicidal in concentrations of 100 to 1,000 units per cubic centimeter. A combination of the two in equal unitage kills amebas in the first generation at a total concentration of 2,000 units per cubic centimeter, and in the second generation at 1,000 units per cubic centimeter. The latter concentration is found not to be bactericidal; hence the action is probably a direct one rather than an elimination of necessary bacterial products. The authors suggest that the combination of penicillin and streptomycin may have therapeutic usefulness, especially in preference to intrinsically more toxic agents, such as emetine hydrochloride. Such a therapy might be expected also to destroy the secondarily invading bacteria, with clinical benefit.

**Immunity to Yellow Fever Six Years After Vaccination.**—Dick and Smithburn present evidence which indicates that immunity to yellow fever endures for at least six years after inoculation with 17D yellow fever vaccine of adequate potency. They stress that there is no significant difference either in the percentage developing antibodies or in the duration of the immune response, when children are compared with adults. This is of importance in the formulation of public health regulations and, in the opinion of the authors, no distinction need be or should be made in the application of these regulations with respect to age. Yellow fever vaccination certificates should be accepted as valid for at least six years after appropriate inoculation with potent vaccine.

**Calcium Metabolism with Spinal Cord Injuries.**—Freeman directs attention to the high incidence of calculi of the urinary tract in patients with paraplegia. The report is based on clinical observation, particularly with regard to the calcium metabolism made on over 700 male adults (ages 18 to 50) who had suffered injury to the spinal cord during and shortly after World War II. The incidence of calculi of the urinary tract during prolonged recumbency was found to be between 23 and 35 per cent. The author feels that, while considerable emphasis has been placed on the role of recumbency, insufficient stress has been placed on weight bearing. It was found that ambulation reduces the incidence of calculi to such a degree that the presence of a calculus can be taken as an indication of the failure to ambulate sufficiently. Neurogenic ossifying fibromyositis is discussed as a reflection of the aberrant state of calcium metabolism in the presence of infectious and inflammatory processes.

**Fistulas from Diverticulitis of Colon.**—Mayfield and Waugh reviewed 46 cases of diverticulitis of the sigmoid colon in which there were bladder or cutaneous fistulas and in which a segment of colon had been removed surgically at the Mayo Clinic. They discuss 17 cases in which sigmoidocutaneous fistulas have occurred. The excised segment of the colon presented many diverticula. The wall of the bowel was involved in a chronic extramucosal proliferative inflammatory process. Areas of necrosis, abscess formation and perforation were seen. The presence of the fistulas was accompanied by abdominal pain, constipation, chills and fever. Each fistula followed some type of surgical operation, usually incision and drainage for an acute suppurative process within the abdomen. These patients had had symptoms suggestive of diverticulitis for an average of approximately 2.5 years when their fistulas developed. The fistulas had been present for an average of approximately 1.5 years when the patients came to the clinic. Roentgenologic examination of the colon was the most important aid in diagnosis. Other types of internal fistulas were present in about one third of the cases. Fistulas of this type tend to close spontaneously and should be allowed ample time, approximately twelve months, to do so. When surgical treatment is carried out, excision of the diseased segment of colon should be done and should usually be preceded by a temporary transverse colostomy made six months prior to resection. The choice of procedure should depend on the conditions present in the individual case. In this group of 17 patients with sigmoidocutaneous fistulas there were eighteen segmental resections of the colon with no operative deaths. Sixteen patients were relieved of their external fecal fistulas.

**Calcifying Epileptogenic Lesions.**—Penfield and Ward say that their attention was called to the occurrence of calcified lesions in the temporal lobe of patients with epilepsy when they were consulted by a man aged 21 because of epileptic seizures. His attacks were characteristic of temporal lobe origin and roentgenograms demonstrated a peculiar intracerebral calcification in that lobe. In order to gain an idea of their frequency, cases of calcified epileptogenic lesions of the temporal region were collected at the Montreal Neurologic Institute for a six year period. The lesions in 5 of the 12 cases were of the type designated as hemangioma calcificans. In 2 of the remaining 7 cases, the tumor was a racemose hemangioma; in 1, a bony arachnoidal plaque, and in 2, a post-traumatic degenerative calcification of an intracerebral hematoma; in 2 cases the diagnosis was tuberculoma, although there was no verification of this. All the lesions called hemangioma calcificans occurred in the temporal lobe and had been producing seizures for one to thirty years. Four of them were successfully removed at operation. The authors hope that in the future this type of lesion may be recognized and treated.

**Electric Shock in Manic-Depressive Psychosis.**—Huston and Locher compared two groups of patients with a diagnosis of manic-depressive psychosis: a control group of 80, and a group of 74 who were treated with electric shock. These groups were comparable in most respects. The authors arrive at the conclusion that electric shock therapy is indicated in the treatment of manic-depressive psychosis (depressive type, mixed type, perplexed type and type with paranoid features). Shock therapy produces a rate of recovery as high as that of spontaneous recovery, reduces the incidence of suicide, probably prevents deaths and shortens the duration of depressions. It should be emphasized that the length of a depression cannot be predicted in a given case and that some depressions, particularly in older patients, may be very long—the longest in the control series being ten years.

**Three Embolectomies in Patient with Bacterial Endocarditis.**—Scott and Williams present the case of a young man with bacterial endocarditis which illustrates the value of prompt embolectomy in three successive episodes of arterial embolism. The case illustrates the value of prompt recognition of the situation in repeated episodes of peripheral embolism and the desirability of close cooperation between medical and surgical services in utilizing this treatment. Arterial embolism is a true surgical emergency, and a diminished cardiac reserve should not be a deterrent to arterial embolectomy, with local or regional anesthesia. Lumbar sympathetic block was not performed before the second embolectomy because a spinal anesthetic, accomplishing the same purpose, was given almost immediately. During the second and third embolectomies no excessive bleeding was encountered, despite the fact that the patient was fully dicumarolized. All wounds healed by first intention without hematoma or ecchymosis. Although penicillin has improved the prognosis for patients with bacterial endocarditis, several observers have noted an increased incidence of embolism since the advent of intensive penicillin therapy of this disease. It is possible that, in the future, cases of this type will be more frequently encountered.

**Ligation of Carotid Arteries for Neoplasms of the Head and Neck.**—Vosseler and Ficarra show that in the treatment of eroding neoplasms of the head and neck ligation of the major arteries supplying these anatomic areas may become a necessity for the preservation of life. It may be necessary to ligate the common carotid artery or the external carotid artery, and sometimes certain of its branches. Ligation of these vessels is advocated (1) to protect against bleeding, as a preliminary step to a radical surgical procedure on the head or neck; (2) to control active hemorrhage, and (3) to diminish the blood supply to inoperable neoplastic lesions. The authors discuss the approach to the carotid sinus and present observations on 26 patients in whom ligation of the carotid arteries was performed for advanced malignant neoplasm of the head and neck. The survival of 21 patients indicates that this procedure is not associated with a formidable mortality. Follow-up studies on these patients indicate that the longest survival after operation was three years. Ligation of the carotid arteries is advocated as a valuable aid in the management of patients with advanced malignant neoplasms of the head and neck.

**Carcinomas of Thyroid and Lateral Aberrant Thyroid Cancer.**—Wozencraft and his co-workers present several cases which illustrate the difficulty of establishing a valid diagnosis of "lateral aberrant thyroid" carcinoma. The sequence of events in these cases would have served to support such a diagnosis had investigation ceased with the removal of the tumors of the neck or with the usual pathologic examination of thyroid tissue subsequently resected. In each case there was an encapsulated mass in the neck containing a thyroid tumor of papillary and follicular structure, and, after the diagnosis made on this first tissue investigated, hemithyroidectomy was done in 2 cases and thyroidectomy in the third. Subsequent procedures resulted in the discovery of similar tumor tissue within the thyroids. The important fact is that careful gross examination did not reveal the lesion within the thyroid; the cancers were discovered only after exhaustive microscopic study of the thyroid tissue. The authors feel that at present there is enough information about the behavior of papillary thyroid carcinoma to account for many events that formerly seemed to require the "lateral aberrant" theory for satisfactory explanation. The slow growth of many of these tumors and the survival for decades of patients with metastasis no longer need preclude the conception that these tumors are malignant. In a large proportion of reported cases of "lateral aberrant thyroid" tumors, similar tumors have been found in the thyroid when it was explored. These findings can be explained more readily by the concept that they represent primary thyroid tumors with metastasis than is possible with the "lateral aberrant" concept.

**Effect of Sex Hormones on Carcinoma of Breast.**—Taylor and his associates observed the effects of estrogenic substances in the last eighteen months on 42 patients with advanced inoperable carcinoma of the breast. They selected 29 patients with advanced carcinoma of the breast for androgen therapy. In this group there were more patients of younger age and more with osseous metastases than in the group given estrogens; included here, too, were patients who showed a poor response to estrogens. It was found that diethylstilbestrol and ethinyl estradiol produced regression in primary lesions and in soft tissue metastases of cancer of the female breast and apparent inhibition of osseous metastases in certain cases. These effects were found in no more than half the patients treated. Age was the only clearly determined factor influencing the response of these patients to estrogens. The most satisfactory results are obtained in patients more than 60 years of age. Apparent acceleration of tumor growth was occasionally produced by estrogens in younger patients, less often in older ones. Androgens produced reduction in soft tissue, as well as in osseous metastases in some cases. The response to androgens is similar to that of estrogens, except that androgens are effective in both younger and older age groups, whereas estrogens may more frequently cause acceleration of growth in the younger age group. Some patients seem to respond equally well to either drug, while others respond to neither. Androgens also occasionally produce acceleration of tumor growth. Androgens controlled the pain and produced recalcification of osseous metastases more efficiently than estrogens. Neither estrogens nor androgens produced a permanent control of metastatic breast cancer.

**Use of Nitrogen Mustards in Carcinoma.**—Karnofsky and associates have obtained, in the course of their study of the effects of the nitrogen mustards on various types of neoplastic disease, a remarkable temporary remission in a patient with an anaplastic carcinoma of the lung. This observation prompted the more extensive trial of the nitrogen mustards in primary lung carcinoma. Methyl-bis (beta-chloroethyl) amine hydrochloride ($HN_2$), a nitrogen mustard, was used in the treatment of 35 patients with inoperable carcinoma of the lung. In nearly three fourths of the patients some clinical improvement occurred. This was evidenced by an alleviation in symptoms such as cough, dyspnea, hemoptysis, pain, weakness and the syndrome associated with obstruction to the superior vena cava and by such objective changes as regression of pulmonary and metastatic lesions and absorption of pleural effusions. The improvement usually lasted from two weeks to two months, and further courses of the drug were usually not as effective as the first. In the rapidly growing, anaplastic lung cancer, the nitrogen mustard frequently alleviated symptoms and appeared to interrupt the course of the disease briefly; here it may be more effective and sometimes less hazardous than roentgen therapy. Some clinical improvement was produced also in the more slowly progressing lung tumors, but in these conditions, particularly in the early stages, roentgen therapy may alleviate symptoms for long periods. It is suggested that nitrogen mustard may occasionally be effective as an adjuvant to roentgen therapy in the palliative management of lung cancer. In 1 patient with a recurrent pleural effusion caused by metastases to the pleura, the intrapleural injection of $HN_2$ prevented further formation of fluid. Of 18 patients presenting a miscellaneous group of tumors the use of $HN_2$ caused brief clinical improvement in 2 with metastatic carcinoma of the prostate no longer responding to hormonal therapy and in 1 patient each with carcinomatosis from a gastric cancer, metastatic seminoma, carcinomatosis from adenocarcinoma of the uterus, neurogenic sarcoma and neuroblastoma.

**The Cornea in Vitamin Deficiencies.**—Bowles and co-workers observed heavy vascularization, thickening and opacity of the cornea in 13 of 22 rats which were placed on a pantothenate-deficient diet when 41 to 61 days of age. Similar but less severe changes were seen in 11 of 23 rats placed on a pyridoxine-deficient diet when 45 to 57 days of age. The changes observed were similar to those observed in early vitamin A deficiency and in deficiencies of isoleucine and of valine.

**Self Selection of Diet.**—Scott and Verney describe experiments on the appetite of rats for thiamine-containing foods. Rats with thiamine deficiency show a preference for diets containing as little as 0.1 and as much as 1,000 parts per million of thiamine. The appetite for thiamine-containing foods was not universal in thiamine-deficient rats, and a small minority always made a poor choice. Rats fed a diet with a critically low concentration of thiamine were in better condition than rats offered a choice between this diet and a thiamine-free diet. Appetite for thiamine-containing foods was not established until the animals were distinctly deficient as judged by weight gain and food intake. It was concluded that while the learned appetite for thiamine can lead to better nutrition than would wholly random eating, it can at best only approach, and under critical conditions fails to approach, the benefit obtained by obligatory eating of a diet prescribed on the basis of known requirements.

**Uremia in Obstructive Uropathy.**—Valk discusses the uremic manifestations found in association with obstructive nephropathy. The uremic syndrome observed in patients with obstructive nephropathy may be explained adequately on the basis of the inorganic acidosis, the hypocalcemia, the dehydration, the anemia and the vitamin deficiency. Correction of these abnormalities has caused disappearance of the syndrome in uremic patients even in the presence of continued nitrogen retention. Since the nonprotein nitrogen of the blood represents only an index of filtration pressure and not necessarily a measure of renal damage, it becomes an index of renal damage only when there is associated acidosis and hypocalcemia. If the nonprotien nitrogen is high and the carbon dioxide-combining power is normal, the patient requires only adequate urinary drainage to release the increased intratubular hydrostatic pressure. It is not necessary to postpone operative procedures in such patients since there is no significant renal damage if the carbon dioxide-combining power is normal. The author operates on patients with obstructive renal disease and with nitrogen retention if the carbon dioxide-combining power is normal, or, if it is abnormal, as soon as the acidosis has been corrected by giving 100 cc. of sixth molar sodium lactate intravenously for each volume per cent the patient's carbon dioxide-combining power is below 60 volumes per cent.

**Khellin in Bronchial Asthma.**—Major studied the effectiveness of a new drug in the treatment of asthma. The drug is khellin or khellinin, the active principle extracted from the seeds of the umbelliferous plant Ammi visnaga, known in Arabic as *Khella,* which grows wild in the Mediterranean area and in Arabia. He reviews reports on this drug published by Anrep and others in the British literature. He obtained a limited supply so that he could treat 12 patients, all of whom had severe bronchial asthma and could be relieved during attacks only by doses of epinephrine or aminophylline so large as to be regarded as potentially dangerous. All had found diphenhydramine hydrochloride and tripelennamine hydrochloride disappointing. With the exception of 1 of the patients, who could not take the drug, all experienced great relief from the use of khellin. The author concludes from his admittedly limited experience that khellin is of great value in bronchial asthma. The drug is still expensive.

*Vagotomy for Peptic Ulcer. J. E. Summers.—p. 209.
Treatment of Tinea Capitis in General Practice. L. Carrick.—p. 213.

**Present Status of Treatment of Peptic Ulcer.**—Walters and associates of the Mayo Clinic report on a series of 177 patients, 83 of whom had been previously reported. In this series vagotomy was done with or without other gastric operations, and the late results were considered excellent in 79 per cent of the cases. There were 5 hospital deaths or a mortality rate of 2.8 per cent. Disturbances of motility occurred in the immediate postoperative period in 19 cases and in 14 persisted for three and a half to eighteen months. In the 77 patients of series 1, 5 patients had proved recurring ulcers and in addition 9 had recurrence of the symptoms of ulcer and one could not help considering the possibility of recurrence of the ulcer. The total of these showed an incidence of 18.2 per cent of patients who had had a persistence or recurrence of their ulcer symptoms. In 11 of these 14 cases, in which insulin tests were made after operation, results were negative. In 7 instances of gastrojejunal ulcer after gastroenterostomy, in which the gastroenteric anastomosis and the gastrojejunal ulcers were removed, continuity of the gastrointestinal tract was restored and vagotomy was performed. Two of the patients later had abdominal pain, loss of appetite and weight, and craters of duodenal ulcers were seen on roentgenologic examinations months later. This incidence of recurrence is only slightly lower than it is when the same procedures are employed without vagotomy. It would seem that the Hollander insulin test does not always indicate the completeness of vagotomy, or that complete vagotomy is not necessary in every case to accomplish relief of pain and other desirable results.

**Vagotomy in Peptic Ulcer.**—Summers shows that the problem of peptic ulcer in general, and that of duodenal ulcer in particular, has not been solved. He believes that subtotal (partial) gastric resection is the best method of treatment for chronic gastric ulcer. Vagus nerve resection, by interrupting the cephalic (psychic) phase of gastric secretion, diminishes the acidity of the gastric secretions. This is of great importance in the human being, in whom the psychic phase predominates. Inasmuch as hyperacidity is the cause of peptic ulcer, especially of duodenal and stomal or jejunal ulceration, vagus nerve section rests on a sound physiologic basis. The clinical results reported from vagus nerve section for peptic ulcer are, for the most part, unusually favorable.

**Gastric Ulcer.**—According to Welch and Allen, diagnosis of gastric ulcer was made in 512 patients, 379 men and 133 women, in the Massachusetts General Hospital during the period 1938 to 1947. The average age of the patients at admission to the hospital was 55; since the duration of symptoms before admission averaged five years, the average age at onset was 50, in contrast to duodenal ulcer, in which the average age at onset of symptoms is about 30. Differential diagnosis of ulcer and cancer cannot be made by present technics in about 10 per cent of the cases. From the point of view of cancer control all gastric ulcers should therefore be operated on at once. Following these principles 97 per cent of 295 patients in this series who had resections for gastric ulcer were treated correctly. The 9 patients (3 per cent) who were followed an inordinate period before resection were exactly equal in number to the deaths after resection. If medical therapy is elected (217 cases), stressing the operative mortality, the discomforts of operation and the postgastrectomy symptoms that may appear, such cases must be carefully selected, studied by the best radiologist and gastroscopist available, and followed vigilantly with early recourse to surgery if healing is not prompt. New operative technics provide satisfactory excisional surgery for ulcers of the cardia. Radical surgery for hemorrhage, the most common complication of gastric ulcer, is both safe and desirable. The authors conclude that surgical therapy is indicated in approximately 75 per cent of the patients with gastric ulcers and that excellent results are to be expected after gastric resections.

**Pulmonary Hazard of Ingestion of Mineral Oil.**—Schneider reports 5 cases of oil aspiration pneumonitis in 5 ambulatory male patients between the ages of 60 and 67 who have been habitually taking mineral oil for laxative purposes. The gravitational distribution of the lesions at the lung bases, more on the right than the left, and ultimately in both lower lung fields, and the paucity of symptoms and physical signs, at least in the early phases of this man-made disease, are emphasized. It appears clear that it takes some time for a roentgenologically evident pulmonary reaction to this bland, liquid foreign body to develop. Good nutrition, comfort and general well-being of the patient are striking in the presence of even extensive pulmonary involvement. As the pulmonary reaction to the liquid petrolatum piles up to an imposing roentgenographic appearance, the patient becomes noticeably dyspneic on exertion and a hacking cough may develop. Because of the age of these patients, if the lesion is one sided, the common error is made of calling this benign disease a malignant neoplasm and subjecting the patient to needless lobectomy or pneumonectomy. Examination of the sputum for oil droplets and an aspiration biopsy of the affected lung may be of aid in establishing the diagnosis. Early lipid pneumonia changes will ultimately resolve if the taking of mineral oil is discontinued. Three of the 5 patients were picked up on tuberculosis case-finding surveys and all 5 were seen within a two year period. Many more such cases will be discovered in older population groups if the index of suspicion of the disease remains high.

**Encephalitis Complicating Antirabies Vaccination.**—Pickar and Kramer report 1 case of encephalomyelitis without paralysis complicating antirabies vaccination in a man aged 26 who had been bitten in the right leg by a cat, the brain of which had shown inclusions compatible with diagnosis of rabies. Manifestations of allergy were absent during the early part of the course of vaccination with phenol-killed vaccine. After seven injections erythema and swelling occurred at the sites of inoculation. There was a gradual increase in severity of manifestations with each succeeding treatment. On admission to the hospital the patient presented a picture of encephalitis and beginning circulatory collapse. One hundred milligrams of diphenhydramine hydrochloride (benadryl®) was given intravenously in 1,000 cc. of 5 per cent dextrose in sodium chloride solution and 100 mg. was given by mouth four hours later. Prompt improvement resulted in all symptoms. Treatment was continued in doses of 100 mg. orally three times daily, but the patient became extremely somnolent and after nine doses the drug was discontinued. During the succeeding twenty-four hours no antihistamine drug was given, and there was rise of temperature accompanied by severe frontal headache and diplopia. Treatment was reinstituted with tripelennamine hydrochloride in doses of 100 mg. three times daily and was continued for the next seven days, at the end of which period the patient was asymptomatic. The possible role of allergy in the causation of this accident was suggested by the observation of a strongly positive reaction to a skin test with a high dilution of the vaccine originally employed and by the total suppression of the skin reaction by use of tripelennamine. Further clinical trial of antihistamine agents in the treatment of the neuroparalytic accidents of antirabies vaccination is warranted.

**Insulin Subshock in Anxiety States.**—Bedell treated 30 patients, 7 men and 23 women between the ages of 19 and 54, with severe psychoneurosis, anxiety being a prominent feature, with a course of subshock insulin, along with psychotherapeutic interviews. The duration of the course of treatment was determined by the individual response to treatment and ranged from one week to eight weeks with an average of three and a half weeks per patient. The insulin in subshock doses appears to relieve tension and to facilitate autonomic balance. With the subsidence of the distressing physical symptoms, such as headache, choking sensations, tachycardia and pylorospasm, and return of a feeling of relaxation, the patient is much more amenable to psychotherapy. After at least six months' follow-up results were as follows: One patient was unimproved, 1 has relapsed, 3 improved markedly but have been lost to follow-up, 1 continued to improve slowly, and 24 were greatly improved or apparently recovered.

**Intrapericardial Foreign Bodies.**—Sandusky reports 2 soldiers, aged 19 and 26, in whom intrapericardial foreign bodies were successfully removed. In one, the foreign body was lodged in the myocardial muscle. In the other, two missiles lay within the pericardial sac adjacent to the great vessels. The author regards the following as indications for the elective removal of foreign bodies from the pericardial sac: (1) to prevent infection, (2) to prevent injury to adjacent structures, (3) to prevent neurosis. In addition, operation is indicated when a foreign body lies within the limits of the pericardial shadow on fluoroscopic examination because of the possible error in localization.

**Carcinoma Cells in Sputum and Bronchial Secretions.**—Woolner and McDonald examined sputum or bronchial secretions for carcinoma cells from a total of 1,600 patients. In 150 of these the results were positive. Sputum was examined while fresh or it was collected in a few cubic centimeters of 95 per cent alcohol. Five smears were made from each specimen. The smears were fixed, while wet, in equal parts of absolute alcohol and ether for thirty minutes. The staining method adopted was Harris' hematoxylin followed by dilute eosin as a counterstain. Carcinoma cells in smears could be distinguished from normal cells by numerous atypical characteristics including large size, variation in size and shape of the cells and of the nucleus, the nuclear-cytoplasmic ratio, hyperchromatism of the nucleus and the presence of large nucleoli. The appearance of carcinoma cells in sputum and bronchial secretions varies with the histologic type of tumor in the bronchus. Cancer cells originating in a bronchogenic carcinoma of small cell "oat-cell" type or in a keratinizing squamous cell type provide the most distinctive morphologic characteristics. In the more undifferentiated tumors, a diagnosis of "carcinoma cells present" was made without reference to histologic type. In 146 of the 150 cases the source of the atypical cells was believed to be a tumor in the bronchial tree. In 141 of the 146 cases a final diagnosis of carcinoma of the lung was made. In 3 cases diagnoses made on the basis of smears were proved to be false positive. In 2 cases the final diagnosis was not definitely established. Carcinoma cells in sputum or bronchial secretions provided the only preoperative microscopic evidence of cancer in 25 of a total of 58 cases in this series, in which surgical exploration was carried out. Of 24 cases of bronchogenic carcinoma in which the lesion could be removed, cancer cells in the smears provided the only microscopic evidence of cancer in 9 cases.

**"Vertical Epidemic" of Mammary Carcinoma in Mice.**—According to Gross, recent observations on mouse mammary carcinoma may fundamentally influence the approach to the problem of cancer in general. Mammary carcinoma of mice, a disease essentially similar to breast cancer of women, is caused by a filterable agent, which is transmitted from one generation to another through the milk of nursing females. This agent can be destroyed by heating to 61 degrees C. for thirty minutes; i. e., it would not resist pasteurization. The agent has antigenic properties and can be neutralized in vitro by a specific immune serum. The development of mammary carcinoma in mice can be prevented by isolating the newly born animals from their potentially cancerous mothers and by having them nursed by female mice whose milk is free from the tumor agent. A female mouse nursing her young may appear healthy while she is infecting her offspring with the tumor agent. The only indication suggesting that she discharges the tumor virus is her record showing that mammary carcinomas developed in her female ancestors. The law of obligate communicability long established for other infectious diseases appears to be valid also for breast cancer of mice. The transmission of the mammary carcinoma agent occurs only from one host to another of successive generations. The term "vertical epidemic" has been suggested for this type of transmission. Many parasites of plants and insects follow this pattern of transmission, passing from one host to another through either seeds or ova. "Vertical epidemic," however, should not be confused with inheritance; these are two fundamentally different phenomena. There is a possibility that mammary cancer of other mammals, including man, may also be caused by agents similar to that responsible for mouse mammary carcinoma. If this assumption is correct, women who have a family history of tumors should not nurse their babies; artificial feeding or feeding with pasteurized human milk should be substituted. This preventive measure may interrupt the flow of the virus and eradicate human breast cancer within one generation; breast nursing could then be resumed in later generations. It is possible that mammary carcinoma of mice is not exceptional in its etiology. Other malignant tumors may eventually prove to be caused by transmissible agents. It would then be logical to assume, however, that milk *is not the only means of transmission of such agents*; transfer through ova, and otherwise, would also have to be considered. The hypothesis is advanced that there exists a group of viruses causing various malignant tumors, which could live in close association with normal cells, and usually cause no symptoms of disease. They would be transmitted among hosts of successive generations; i. e., vertically. In most instances the carriers would never show tumors. Occasionally, however, prompted by obscure factors, the tumor virus would become activated, causing a local new growth. Because of the existence of many asymptomatic carriers, and the occasional "skipping" of generations, it would become possible to trace the host-to-host passage of the "vertically" transmitted tumor agents only when complete records are on hand covering the span of many successive generations.

**Thoracic Duct: Injuries and Their Treatment.**—Holmberg describes 3 cases in which the thoracic duct was injured in the course of operations and 1 case of subcutaneous rupture of the duct. In 2 of the cases repeated operations were necessary, in 1 case tamponade and in the other thoracotomy with ligature of the thoracic duct. In the third case, the injury was discovered at operation and the two ends of the duct were sutured. In the fourth case, the injury healed spontaneously. All these patients recovered without a continued secretion of chyle. The author reviews the anatomy of the thoracic duct, the physiology of the lymphatic vessels and the literature on the treatment of injuries to the thoracic duct. He stresses that in the event of injury to the duct or its larger afferent branches, the disturbed fluid balance should be restored, so far as possible, to normal values, which requires an energetic administration of albumin, a supply of fluid and salts (calcium, etc.) and, in the case of a protracted fistula of the lymphatic duct, the administration of vitamins. The supply of fat should be reduced to a minimum. Atropine may be tried, in order to diminish the flow of chyle. Ligature is recommended in case of injury to the cervical thoracic duct. Should it fail, tamponade can be done, which should then be left undisturbed for at least eight days. In case of injury to the intrathoracic part of the duct, an expectant procedure is recommended. Should this not produce the desired result, a ligature must be made both centrally and peripherally to the injury. As a third expedient in cases of injury to the intrathoracic part of the duct, drainage outward according to the method of Brown may be tried. This method is of palliative nature only, being intended to prevent the formation of chylothorax. Minor injuries to the thoracic duct may heal spontaneously. Owing to the advances in fluid therapy and in thoracic and cervical surgery, the prognosis of injuries to this duct is relatively favorable.

**Hodkgin's Disease.**—Herve reports 125 patients, 86 male and 39 female, between the ages of 4 and 73 years with Hodgkin's disease. The highest incidence was in the age groups between 30 and 50 years. The cervical lymph nodes were involved primarily in 59 patients (48 per cent), the subclavicular lymph nodes in 27 patients (21.6 per cent) and the axillary lymph nodes in 16 patients (12.88 per cent). Secondary involvement of the lungs, mediastinum and pleura occurred in 52 patients, abdominovisceral involvement in 23, and splenomegaly in 17 patients. Local roentgen treatment is the method of choice. The zones which are involved clinically must be irradiated as soon as the diagnosis has been established. Prophylactic irradiation of lymph nodes which have not yet been affected by the disease does not delay the progressive course of the disease. Maintenance roentgen treatment in the absence of clinical manifestations is not indicated for the same reason. The average survival time between the first irradiation and the fatal outcome was 26.4 months. The average time elapsed between the onset of symptoms and the first treatment was 13.2 months. The total average survival time was 39.6 months. Twenty-three of 108 patients (20.3 per cent) were alive five years after treatment was instituted and 6 of 72 (8.3 per cent) were alive ten years after the initiation of the treatment. One patient had only one recurrence in seventeen years, and 1 patient had two recurrences in fourteen years. Local roentgen therapy is the rational palliative treatment for Hodgkin's disease, the etiologic factor of which has not yet been determined. It does not seem likely that new irradiation technics will improve the actual results of treatment, but combined treatment with roentgen rays and derivatives of dichlorodiethylsulfide (yperite) has been given a trial since January 1947.

**Dichlorodiethylsulfide Derivatives in Cancerology.**—Herve treated 31 patients, 13 with Hodgkin's disease, 5 with lymphosarcoma, 1 with myeloid and 1 with lymphoid leukemia and 11 with allied and miscellaneous disorders with methyl-bis(beta-chloroethyl)amine hydrochloride at the Anticancer Center of the University of Liége. Acute lymphogranulomatosis did not respond favorably to the nitrogen mustard therapy. This treatment is indicated in the chronic type. The general condition in chronic disease was improved, temperature dropped, pruritus subsided, the eosinophile leukocytes disappeared and adenopathies of medium degree receded rapidly. Splenomegaly and massive adenopathies were resistant. Sedation of pain occurred rapidly. Clinical periods of remission lasted from one to five months. A remission with disappearance of adenopathies was obtained in 1 patient who was resistant to roentgen rays. Tumor masses disappeared more rapidly as the result of nitrogen mustard therapy in 5 patients with lymphosarcoma than in those with Hodgkin's disease, and objective and subjective improvement seemed to last longer. One patient who was given four injections of the drug responded less favorably to the last two injections. Roentgen treatment seemed to be superior to nitrogen mustard therapy, but the latter may be used in patients who have become resistant to roentgen treatment. Nitrogen mustard therapy failed in acute leukemia but proved equal in value to roentgen treatment in chronic leukemia. Nitrogen mustard therapy should be employed in patients with lymphoid neoplasia who have become resistant to irradiation. Nitrogen mustard therapy and roentgen treatment should be combined when each of the agents alone has been found ineffective. Nitrogen mustard therapy may be useful as treatment of an attack in neoplasm with rapid growth and in generalized lymphoid disease. Nitrogen mustard therapy alone or combined with irradiation treatment appears to have a definite place in the treatment of the neoplasms discussed.

**Hypoprothrombinemia After Penicillin Treatment in Infants.**—Axtrup says that during 1947 in the Pediatric Clinic of Lund University 3 infants, all less than 6 months old, were observed who showed a fall in the prothrombin content during treatment with penicillin. Two of these infants showed a hemorrhagic tendency, which in 1 case was so severe that the hemorrhages contributed to the fatal outcome. Literature contains reports of hemorrhage as a complication in penicillin treatment. Such phenomena result mainly when the penicillin is applied intrathecally, but similar symptoms have also been noted after subcutaneous or intramuscular injection—though only when the doses were very large. It is possible that these hemorrhages may be attributed to a lowering of the prothrombin by the penicillin.

**Exchange Transfusion in Erythroblastosis Fetalis.**—Mitera and associates resorted to exchange transfusions in 9 infants with icterus gravis neonatorum. Observations on these patients convinced them that this treatment is justified when the anamnesis and the serologic findings indicate erythroblastosis, even if the clinical picture is not fully developed in the newborn. Positive serologic findings are: (*a*) incompatibility of baby's and mother's Rh system; (*b*) signs of isoimmunization; i. e., Rh antibodies in mother's and baby's serum. The sooner exchange transfusion is given, the smaller is the damage caused to the organism by Rh isoimmunization and the better the results. It is essential to know the mother's serologic status during pregnancy and, if necessary, advise a premature delivery. The authors injected citrated blood into the cubital or saphenous vein and withdrew blood from the radial artery. They recommend injection of an amount of blood equaling two tenths of the baby's weight and the withdrawal of about 80 cc. less.

**Cardiac Symptoms and Vasoneurosis Caused by Endocrine Disturbances.** — Schliephake refers to an increase in patients who complain of palpitation, vertigo, malaise and a sensation of pressure in the region of the heart. This clinical picture has been given various designations such as neurocirculatory dystonia, exertion syndrome and, in young persons, cor juvenile. These patients are often treated like those with cardiac defects, because the electrocardiographic changes are overestimated. The function of the heart muscle in these persons is not impaired; only the sympathetic innervation of the heart and of the peripheral circulation is involved. The equilibrium between the vagus and the sympathetic, or between the adrenergic and cholinergic systems, is disturbed. These disturbances in the sympathetic system are not primary but are the result of disturbances in the endocrine system. Some of the symptoms suggest adrenal disturbances, but it is impossible to say whether the primary failure is in the chromaffin system or whether it is due to a deficiency in adrenotropic or corticotropic hormones of the hypophysis. The author studied blood sugar in these patients, giving particular attention to the contrainsular hormone of the hypophysis and its behavior under the influence of short wave irradiation of the hypophysis. He found that whereas in healthy subjects short wave irradiation of the hypophysis is usually followed by a noticeable increase in the sugar content of the blood, in the patients with the aforementioned disorders the opposite tendency prevails. Impairment of the function of the hypophysis seems to play a part. The malnutrition prevailing in recent years may be responsible for the increase in these disorders. The author believes that advice against physical exertion (often given because heart disease is suspected) is not justified in these patients. On the contrary, physical activity is to be recommended.

**Chronic Subdural Hematoma.**—Meurer and Heberer discuss the clinical aspects of chronic subdural hematoma on the basis of 2 case histories. Acute subdural hemorrhages are usually the result of severe traumas, while the chronic forms are generally caused by milder trauma. Sometimes the patient does not even recall the accident. The interval between the accident and the appearance of symptoms is longer in the chronic than in the acute hematomas. Vascular anomalies, hypertension or alcoholism may be contributing factors, but this has not been definitely elucidated. Treatment consists in surgical removal of the hematoma. The authors feel that the operation recommended in 1926 by Cushing and Putnam with complete removal of the capsule of the hematoma following osteoplastic opening of the cranium is more extensive than necessary, and is employed now only when it is impossible to decide before the operation whether a subdural hematoma or a tumor exists. The parietotemporal trepanation is a less extensive, less trying, but still effective operation for the removal of the subdural hematoma. The capsule of the hematoma is not removed in this operation, but the result is nevertheless quite satisfactory.

**Sodium Thiosulfate in Pulmonary Tuberculosis.**—Albert-Weil treated many patients with pulmonary tuberculosis, 12 of whom, 4 men and 8 women between the ages of 20 and 48, are reported in detail, with intravenous or subcutaneous injections of sodium thiosulfate combined with intramuscular injections of watery extract of bovine pancreas and lipid extract of spleen. Two cubic centimeters of a solution of 0.16 Gm. of sodium thiosulfate in 2 cc. of distilled water were injected daily for thirty days. At an interval of ten days a second course of these injections was given, and treatment was continued for months and even years with a total dose of 25 to 30 cg. of the drug per kilogram of body weight and six to seven courses of injections per year. At the same time repeated courses of twelve combined injections of 2 ampules of pancreas extract and of 1 to 2 ampules of lipid extract of spleen were given at intervals of ten to fifteen days. During treatment, blood cell counts, sedimentation rate tests, blood urea determinations and examinations of sputum and urine were carried out. Adjuvant treatment consisted of oral administration of vitamin D and calcium, of synthetic estrogens in certain female patients and of strict rest. The clinical picture improved rapidly, and there was progressive clearing of the pulmonary lesions seen on roentgenologic examination. It is suggested that sodium thiosulfate, an agent which regulates the ratio of glutathione in the blood and in the tissues, exerts a regulator action on the hepatic function, which plays an important part in tuberculosis. In addition, the drug has a desensitizing, antiflocculating and antianaphylactic effect. It makes Koch bacilli lose their acid resistance. The importance of prolonged treatment with divided doses of the drug and its synergy with watery extract of bovine pancreas and lipid extract of spleen are emphasized.

Lymphosarcoma Presenting as Edema of Eyelids. M. T. F. Carpendale. —p. 305.

**Congenital Absence of Gallbladder.**—According to Smyth, congenital absence of the gallbladder is a rare anomaly in man. In most cases of congenital absence of the gallbladder there is gross malformation or agenesis of the extrahepatic ducts. The large majority of children with this condition die in the first three to six months of life. The author discusses the theories that have been advanced to explain the absence of the gallbladder, reviews the clinical features that characterize complete absence of the gallbladder and cites the case of a woman, aged

72, whose symptoms were diagnosed as chronic cholecystitis. At operation the gallbladder was not found. The fossa for the gallbladder was absent, and the recognized abnormal sites for the gallbladder were explored without result, but a large stone was palpated in the common duct and removed. Twelve days after operation the bile ducts were outlined with an opaque medium introduced through the T-tube. The first picture showed dilatation of the ducts but no evidence of gallbladder or filling defect due to stone. A second radiogram, taken after the hypodermic injection of morphine showed the stimulating effect of morphine on the sphincter of Oddi, causing strong contraction and thus helping to outline the bile ducts to the full extent. The patient made a good recovery. So far as could be ascertained, this case is the first in which cholangiography was used to confirm the diagnosis at operation of congenital absence of the gallbladder. It is commonly held that when the gallbladder is removed the bile ducts dilate and take over in part the functions of the gallbladder, but it has been noted in some cases of congenital absence of the gallbladder that the ducts are not abnormally dilated. Some believe that bile ducts do not become dilated unless stones are a complication. In their opinion congenital absence of the gallbladder, or removal of the organ by operation, leads to a compensatory relaxation of the sphincter rather than dilatation of the common bile duct.

**Erythroblastosis Fetalis.**—Sadowsky and Brzezinski direct attention to the great discrepancy between the incidence of erythroblastosis fetalis and that of Rh-incompatible marriages. Insufficient maternal immunization as a result of the limitation of pregnancies has been one of the most generally accepted explanations. Thus, according to the original theory of Levine, only the second or third pregnancy in Rh-incompatible marriages can sufficiently immunize the mother to produce erythroblastosis fetalis or hemolytic disease of the newborn. To test this explanation the authors studied a group of Rh-negative women who had married Rh-positive men and had had a considerable number of pregnancies. The incidence of Rh-negative women among the obstetric material of these authors was 9.6 per cent and the incidence of erythroblastosis fetalis 0.05 per cent. The authors selected 32 Rh-negative women who were married to Rh-positive men and had had 6 to 14 pregnancies and at least 6 deliveries at term. Their blood was repeatedly examined for agglutinating, blocking and conglutinating Rh antibodies before, during and after the last pregnancy, and in some cases before, during and after the last two pregnancies. A group of 34 Rh-positive women who had 6 to 14 pregnancies were used as controls. The authors found that repeated incompatible pregnancies (6 to 14) are in themselves insufficient to cause maternal immunization. This seems to invalidate the view that hemolytic disease of the newborn is a relatively rare condition because of the limitation of the number of pregnancies in Rh-negative women married to Rh-positive men.

Treatment of Ventricular Paroxysmal Tachycardia. H. A. P. Hartog and J. E. van Beynum.—p. 256.

**Vitamins in Treatment of Pregnancy Toxemias.**—Bijdendijk and van Assen resorted to the use of vitamin E in women with toxemia of pregnancy, because it has a favorable influence on hyperestrinism. Vitamin B complex was administered, because it promotes the detoxication of estradiol in the liver. Observations on the first patient suggested that the favorable effect of these vitamins on the toxemia of pregnancy is due chiefly to vitamin E and that the vitamin B complex has a supporting effect. The authors cite 5 patients who were treated with these vitamins and in whom pregnancy toxicosis was influenced so favorably that the pregnancy could be carried to a favorable termination without a salt-free diet.

*Leiomyosarcomas in Stomach and Intestine. B. Fretheim.—p. 69.

**Leiomyosarcomas in Stomach and Intestine.**—Fretheim states that leiomyomas constitute 1 per cent of the neoplasms in the gastrointestinal tract. They occur most often in the stomach and small intestine and are to be considered potentially malignant. Their localization is in the submucosa or subserosa or both. They are characterized by slow growth over a period of years, tendency to necrosis and late development of metastases. The chief symptom is usually a sudden severe melena. Leiomyomas with subserous localization give symptoms more by their size and location. Treatment consists in radical removal. Roentgen treatment is of doubtful value. Preoperative diagnosis is often possible. Three cases of leiomyosarcoma, 2 in the stomach, 1 in jejunum, and 1 case of leiomyoma in jejunum are described. In the 3 cases with sudden marked melena without preceding dyspepsia, ulceration or signs that there had been ulceration on the mucosal side of the tumor were seen; no signs of metastases appeared although the tumor had apparently existed for eight years in the first case and for thirteen in the third, in which signs of spontaneous recovery were seen; no signs of metastases appeared, although the tumor The first case showed the advisability of radical resection ot the stomach or total gastrectomy in the case of such tumors, as there was recurrence after five years.

*Pachyperiosteoderma (Pachyderma with Sulci with Hypertrophic Pachyperiosteosis of Long Bones). Its Finding in Bronchopulmonary Cancer. M. R. Castex, E. G. Mazzei and F. Schaposnik.—p. 119.

**Pachyperiosteoderma in Bronchopulmonary Cancer.**—According to Castex and collaborators pachyperiosteoderma is a rare condition affecting adults of either sex between the ages of 20 and 40 years. The condition has an insidious onset and a slow course. The changes in the skin are those of pachyderma with fissures. The expression of the patient's face and the appearance of his legs and hands are those of an elderly leper. The changes in the bones are of the acromegalic type. The condition may be associated with bronchopulmonary cancer. The authors report a case of this type in a man 46 years of age, and cite a similar instance from literature in a woman 61 years of age. The authors' patient presented cough, fever, fatigue, chills, frequent perspiration and loss of weight. He complained about articular pain. Roentgen examination showed enlargement of the bones, which was particularly striking at the ankles and the wrists. Roentgen examinations of the thorax showed a dark round shadow in the upper field of the left lung, the size of which rapidly increased. Cachexia, asthenia and arterial hypotension characterized the final stage of the disease, which lasted three years.

*Therapy of Tuberculosis of Lower Lobes of Lung. A. Trenchi and W. García Fontes.—p. 154.
Treatment of Various Types of Tuberculous Empyema. J. A. Sciuto.—p. 192.

**Treatment of Tuberculosis of Lower Lobes of Lung.**—Trenchi and Garcia Fontes state that tuberculosis of the lower lobes of the lung has a tendency to early formation of cavities and to spread to the lower lobe of the contralateral lung. In patients with clinical symptoms and roentgen signs of tuberculosis of the lower lobes and a persistent negative search for tubercle bacilli, differential diagnosis should consider bronchiectasis, a residual cavity of either acute abscess or a basal hydatid cyst, cancer of the lung and chronic pneumonitis. In patients with clinical symptoms, roentgen signs of tuberculosis of the lower lobes and positive sputum, collapse therapy is indicated provided bronchial endoscopy does not reveal bronchial or tracheobronchial tuberculosis. The authors report 7 cases of tuberculosis of lower lobe among 509 cases of pulmonary tuberculosis observed in a pavilion for male tuberculous patients. The cavities were either elastic or semirigid and of a moderate size. They were located either at the apex of the lower lobe or at the posterior basal segment. Initial artificial pneumothorax obliterates the cavities at the aforementioned locations. Failure of artificial pneumothorax is an indication for phrenic paralysis if the cavity is located at any of the segments of the lower lobes of the lungs, with the exception of the posterior basal segment. Cavities at the posterior basal segment are best treated by a lobectomy or the removal of the corresponding bronchopulmonary segment. In some cavities of the lower lobe phrenicectomy followed by pneumoperitoneum gives good results. Giant, fibrous and rigid cavities at any of the segments of the lower lobes constitute surgical problems as yet unsolved.

*Value of Urethane in Treatment of Leukemias and Other Hemopathies. Two Years of Clinical and Hematologic Experience. E. Storti. —p. 549.

**Exsanguination Transfusions in Leukemias.**—Croizat and his co-workers treated 2 patients, 1 man aged 49 and 1 girl aged 15, who had myeloid leukemia, with exsanguination transfusions. The male patient had been treated for six years with roentgen irradiation of the spleen, but this method had become ineffective. Urethane failed likewise. Examination of the blood revealed 2,240,000 red blood corpuscles and 524,000 white blood corpuscles with a formula typical for myeloid leukemia. Four exsanguination transfusions were given within twenty days; the patient received 22.5 liters of blood, while 19.5 liters were withdrawn. Myeloid leukemia in the female patient had been diagnosed only recently. Ten million units of penicillin was given because hereditary syphilis was suspected, but this treatment was ineffective. Blood count revealed 3,820,000 red blood corpuscles and 75,000 white blood corpuscles with a formula typical for myeloid leukemia. Two exsanguination transfusions were given within eight days; the patient received 8.5 liters of blood, while 7.3 liters were withdrawn. The exsanguination transfusions were well tolerated by the patients. In both patients there was a pronounced increase in the number of red blood corpuscles while the number of the white blood corpuscles was diminished; both the young and the adult granular forms of the leukocytes were reduced in number; in both patients the myeloblasts disappeared almost completely. There was first a rise in the leukocyte count and only several hours after the transfusion there appeared a progressive diminution of the leukocytes and particularly of the young types. A true lavage of the bone marrow and of the hemopoietic organs during the first stage may be followed by a specific "antileukosis" during the second stage. Considerable reduction of the volume of the spleen in both patients favors this concept.

**Urethane in Leukemias and Other Hemopathies.**—Storti treated 42 patients, 18 with chronic myeloid leukemia, 4 with lymphatic leukemia, 6 with acute leukemia, 6 with lymphogranulomatosis, 2 with lymphosarcomatosis, 1 with polyglobulism of the Vaquez type and 5 with malignant tumors of various organs, with urethane; 4 normal persons served as controls. The majority of these cases were followed up for two years. Chronic myeloid leukemia is most sensitive to urethane, while lymphatic leukemia is less sensitive; acute leukemia is not influenced by urethane but may be improved by combined treatment with urethane, penicillin and transfusions. The reaction to urethane was less rapid in patients with myeloid leukemia of two years' duration who had received irradiation treatment previously. The splenomegaly of patients with chronic myelosis of four years' duration which had become resistant to roentgen ray treatment receded after the administration of urethane combined with transfusions, but fatal acute leukemia resulted after six months of treatment. Several patients with chronic myelosis who had been treated satisfactorily with urethane showed a noteworthy sensitivity to the action of roentgen rays several months after urethane was discontinued. Urethane should be employed first in all cases of myelosis or chronic lymphadenosis which have not yet been treated by any other method. Treatment with urethane should be instituted with doses of 3 to 4 Gm. daily by mouth and should be continued for long periods after normalization of the blood picture had been achieved, with doses of 2 Gm. daily and with hematologic control every two weeks. It is suggested that urethane acts as an inhibitor of the enzymatic cellular activity. In lymphogranulomatosis the masses of granulation tissue were reduced considerably in volume and in consistency as a result of the treatment with urethane; combined treatment with urethane and weak irradiation at long intervals deserves further trial. In patients with lymphosarcoma the volume of the masses in the lymph nodes was reduced with urethane treatment but the progressive course of the disease continued. Urethane was ineffective in polycythemia.

### 25:709-754 (March 2) 1949. Partial Index

Audio-Electroencephalography and Pentothal Sodium. J. Calvet, F. A. Birague and C. Grèzes-Rueff.—p. 709.

New Achievements in Treatment of Cancer of Rectum. J. Ducuing. —p. 710.

Arterial Hypertension and Its Surgical Treatment (Apart from Hypertension Nephritis). Riser.—p. 714.

*Parallel Sclerosis of Heart and Lung. R. Roques, R. Bollinelli, Parayre, Arlet and Calazel.—p. 721.

*Part Played by Lipocaic Insufficiency in Diabetes in Juvenile Persons. M. Sendrail and A. Bazex.—p. 730.

**Parallel Sclerosis of Heart and Lung.**—Roques and co-workers report 35 patients, 32 men and 3 women, between the ages of 42 and 76, with simultaneous sclerosis of the heart and the lungs. This condition has a predilection for persons over 50. It constitutes in the aged a common feature of cardiopulmonary failure which can be differentiated from pulmonary sclerosis with cardiac involvement and from cardioaortic sclerosis with pulmonary complications. Two phases of the simultaneous sclerosis of the heart and the lungs may be distinguished: The first is characterized by the independent involvement either of the heart or of the lungs. The cardiac lesions are of a vascular nature, while the pulmonary lesions are those of emphysema, apical sclerosis and bronchitis. The second phase is that of visceral interreaction in the course of which cardiac decompensation with predominantly right ventricular failure dominates the clinical picture. In this stage only a thorough analysis of the symptoms will make it possible to ascertain which is primarily pulmonary and which is primarily cardiac. In the majority of the cases death resulted from bronchopneumonia with an infected infarct as the main pathologic factor.

**Lipocaic Insufficiency in Juvenile Diabetes.**—Sendrail and Bazex report 4 boys between the ages of 10 and 19 years and 4 girls between the ages of 2 and 20 years with severe diabetes mellitus of insular type preceding the other symptoms of their syndrome, which consisted of infantilism and nanism, a disturbance of the distribution of fat, hepatomegaly and hyperlipoidemia (Mauriac's syndrome). The pathogenesis was confined to a diabetic lipoidosis. Mauriac's syndrome may be interpreted on the basis of a double functional incompetence of the islands of Langerhans, that concerned with regulation of glycogen storage and regulation of lipids, rather than by assuming a failure of the function of the anterior lobe of the pituitary. The occurrence of lipid hepatitis depends on multiple lipotropic factors, the most active of which is Dragstedt's lipocaic hormone. The lipocaic deficiency may be responsible for the complex of symptoms which characterize the syndrome of Mauriac. Juvenile diabetes appears to combine two groups of manifestations, those due to insulin deficiency and those due to lipocaic deficiency.

# Book Notices

**Office Gynecology.** By J. P. Greenhill, B.S., M.D., F.A.C.S., Attending Obstetrician and Gynecologist, Michael Reese Hospital, Chicago. Fifth edition. Cloth. Price, $5.25. Pp. 461; with 120 illustrations. Year Book Publishers, Inc., 304 S. Dearborn St., Chicago 4, 1948.

In the fifth edition of this useful office manual, the author has made it even more inclusive as a guide for this important branch of gynecologic practice. The book has always been admirably adapted for both the general practitioner and the specialist.

One questions the advisability of many physicians doing some of the more complex procedures in the office, such as sterilization by coagulation of the uterine cornu. The description of local anesthesia for dilatation and curettage also hints that this is an office procedure, which indeed it can be, but should not be frequently, nor should it be done there by many physicians.

Space allotted to older office practices, such as the use of pessaries, douches and pelvic heating, is reduced somewhat, and properly so. However, these portions of the book remain adequate and are most practical.

The chapters on endocrinology and menstrual irregularities are both factual and good. A table of commercial endocrine products will be found in this section and should be useful for occasional reference. The book ends with a chapter that provides excellent information and advice as to the premarital conference and examination—presented in good taste.

The book is remarkable for being so inclusive of nearly every type of office gynecologic procedure. Revision is up to date. As stated in the review of the first edition, it is an authoritative and complete office tool for the physician treating gynecologic patients for the less serious, but often annoying, conditions that can properly be handled in the office by either the general practitioner or the gynecologist.

**Pain Syndromes: Treatment by Paravertebral Nerve Block.** By Bernard Judovich, B.S., M.D., Physician in Charge, Neuralgia Clinic, Graduate Hospital, Philadelphia, and William Bates, B.S., M.D., F.A.C.S., Professor of Surgery, Graduate School of Medicine, University of Pennsylvania, Philadelphia. Foreword by Joseph C. Yaskin, M.D., Professor of Neurology, Graduate School of Medicine, University of Pennsylvania, Philadelphia, Pa. Third edition [of Segmental Neuralgia in Painful Syndromes.] Cloth. Price, $6. Pp. 357, with 181 illustrations. F. A. Davis Company, 1914-16 Cherry St., Philadelphia 3, 1949.

The authors show that, clinically, the interpretation of pain can be greatly facilitated by eliciting hyperalgesic or tender skin zones which accompany pain. The presence of tenderness, and its distribution, whether local or segmental, have been of great aid in diagnosis and therapy.

The work is based on the fact that, clinically, the combination of segmental pain and tenderness usually appears to be due to factors which irritate roots, ganglia or trunks of the spinal sensory nerves, and not due to painful impulses originating in diseased viscera. The authors believe that pain and segmental tenderness of skin in most instances appear to be of somatic origin rather than of visceral origin.

Segmental pain and tenderness is a symptom complex due to toxic absorption, poor posture, trauma, arthritis of the spine, malignant metastases and other contributing factors. The syndrome has no specific origin.

Much attention is given to the abdominal wall neuralgias and other conditions often mistaken for visceral organic disease. The authors stress the clinical value of tenderness and devote much space to therapy, especially the technic of nerve infiltration, which has yielded the most satisfactory relief of pain.

The chapter dealing with brachial plexus pain has been enlarged by the inclusion of a new summary of etiologic factors and a new outline of diagnostic procedures.

The problem of the anterior scalene syndrome is approached by reevaluation of signs and symptoms. Factors are suggested which the authors believe are responsible for failure to obtain relief of pain following scaleniotomy. A method of clinical examination is described to help avoid surgical failures. Conditions which simulate an anterior scalene syndrome are discussed. Distinguishing symptoms and signs of primary and reflex scalene syndromes have done much to help in understanding some of the puzzling pain problems affecting neck, shoulder and upper extremity.

Endometriosis is discussed as a cause of major backache. The intravenous use of procaine as a method of pain control is presented with a mode of action, indications and technic of administration. The technic is given for aborting attacks of migraine in selected cases. A new chapter on atypical facial pain has been added.

**Public Health in the World Today.** Edited by James Stevens Simmons, Dean, Harvard School of Public Health, Cambridge, Mass. Assistant Editor: Irene M. Kinsey. With a foreword by James Bryant Conant, President of Harvard University. Cloth. Price, $5. Pp. 332, with 17 illustrations. Harvard University Press, Cambridge 38, Mass., 1949.

Man, following wars, usually takes a heightened interest in the health of his fellow man. In 1947 and 1948 the Harvard School of Public Health presented twenty-four guest speakers on public health and related subjects. The speeches are divided into four successive subjects: (1) The Profession of Public Health; (2) Public Health in the United States Today; (3) Public Health Programs and Problems Abroad, and (4) Public Health in a New Era.

The history of medicine and nutrition is traced to the present. Although the role of the doctor as leader is undeniable, much of the problem today is outside his domain—in the fields of education, economics and sociology.

The second section, tracing the history of the public health service in the United States since 1798, shows vast organizations at work. The needs are summarized as education of the public, further development of the new field of industrial medicine and surgery, and more psychiatric help. Abroad, the picture is less encouraging. Although the World Health Organization of the United Nations is actively campaigning, without political discrimination, to improve the social and economic as well as the medical well-being of the people, the group does not allot all problems to one agency. Although the war has left Europe with many health problems, the Far East is even more disease ridden and malnourished. In the tropics, the past fifty years have been marked by the advent of tropical medicine and public health programs, but much work is still necessary.

The last section, "Public Health in a New Era," faces squarely the situation in public health today. Formerly serious problems of acute respiratory infections have been brought largely under control, and the diseases of childhood have been similarly replaced by the diseases of old age as the major killers. Of the ten leading causes of death, only premature birth is associated with early life. Heading the list are heart disease and cancer. The public health worker fights these by educating the public to recognize symptoms, by administering tests to locate sufferers and by helping the elderly make the mental adjustments.

Another problem of great importance today has been created by the extensive development of travel. Safety, disease control, sanitation and environmental hazards (especially in aviation) now call for rigid inspection and control.

The advent of the atomic era has introduced still another hazard: radiation exposure. Protection against this danger has led to the development of an entirely new field, called health physics. One of the more important jobs in this work is keeping contact with radiation at a minimum through careful disposal of waste.

As a survey of public health these articles set forth the weaknesses in this phase of social progress which can be corrected if all will work to eliminate them. All weaknesses cannot be listed, but several stand out: 1. Although we have the information to wipe out such scourges as smallpox within a year by universal vaccination or appropriate treatment, preventive medicine has lagged behind in the application of its knowledge. No great disease has actually been banished from the earth by preventive medicine. 2. We have not met the environmental changes which continue to create public health problems. 3. We need well trained and equipped health units, more dentists, more psychiatrists and available psychiatric aid and more research into the diseases of old age. 4. To further these steps and the health of the individual, the public must be educated to the needs of, and the solutions to, the problems.

Public health workers hope through the World Health Organization an almost singular example of international cooperation in sharing of knowledge, personnel and equipment, to see at last a world united.

**Handbook of Midwifery.** By Marageret Puxon, M.D., M.R.C.O.G., Obstetric Consultant, Essex County Council, Essex, England. Cloth. Price, 25s. Pp. 326. Sylviro Publications, Ltd., 19 Welbeck Street, London, W.1, 1949.

This handbook is well written and covers the subject adequately. Evidently, English physicians need such a work, for the author states, "Unfortunately, the increase in antenatal care in this country has so far tended towards excessive interference, so that the stillbirth and neonatal rates remain high, in contrast to the remarkable improvement in maternal mortality in recent years."

The author stresses the use of analgesia in the first stage of labor, especially the use of meperidine hydrochloride in 100 mg. doses. After delivery, leg exercises are begun on the second day. Early rising is not recommended except in patients who have not had perineal repairs. A fourteen day stay in the hospital is recommended.

The chapter on the Rh factor in obstetrics is particularly well written, stating the known facts in an orderly fashion. The advice not to employ version in occipitoposterior positions is open to argument, especially when it is advised for face presentations. Throughout the book the author warns the physician to be on the lookout for shock and postpartum hemorrhage.

The low cervical cesarean section is recommended in preference to the classic. Interrupted nylon® sutures are used to close the wound in the lower uterine segment. No mention is made of the Portes cesarean section in cases of infection. The use of the cesarean section is broadened, and it is recommended for suspected difficult deliveries throughout the book. Unfortunately, symphysiotomy is still recommended.

The chapter on the treatment of immediate partum hemorrhage recommends the hot douche for its control. Also the use of ergonovine maleate injected directly into the uterus through the abdominal wall is stressed, and packing the uterus is recommended as a last resort.

This book is recommended to those who wish a quick résumé as an aid in the care of the obstetric patient.

**Die beiderseitige Nierensteinkrankheit.** Von Dozent Dr. Bertrand Bibus. Band III, Wiener Beiträge zur Urologie. Herausgegeben von Prof. Dr. Richard Übelhör. Boards. Price, $6. Pp. 169, with 40 illustrations. Wilhelm Maudrich, Spitalgasse 1B, Wien IX/2; imported by Grune & Stratton, Inc., 381 Fourth Ave., New York 16, 1948.

This small book devoted to a discussion of bilaterally occurring renal calculi is well prepared. Other monographs in the series are by Drs. Hutter, Glingar and Hyrutschak, all well known contributors to urologic literature, and these monographs are edited by Prof. Lorenz Übelhör. This volume is divided into three parts. First there is a general discussion of the subject, under which etiology, chemistry, course of the disease and its complications, its association with other complicating diseases of the kidneys and roentgen diagnosis are thoroughly considered. The second part is devoted to conservative or nonoperative treatment and the third part to operative therapy. The usual important divisions are made, and there are nine pages devoted to stone in a solitary kidney. Bibus states as definite indications for surgical attack on a stone-bearing solitary kidney: First, colic and hematuria of such degree and so harmful to the patient that the risk of operation is of secondary consequence. Second, recurrent anuria due to stone in an uninfected kidney, even if the immediate anuria can be overcome by ureteral catheterization. He correctly states that repeated instrumentation usually leads to infection and the patient is thereby subjected to added danger. Third, not only the actual complete obstruction produced by a stone in a solitary kidney, but the apparent likelihood or imminence of such a complication. Fourth, acute onset of infection of the kidney or in the perirenal tissues. Fifth, acute anuria produced by stone. As his sixth indication, he says that the decision to operate on a person in a chronic suburemic state is a difficult one, and he elaborates on the age and general status of the patient as being of great importance in the final decision.

Under general considerations of operative technic, he conforms with generally accepted procedures. For example, he does not favor pyelostomy as against nephrostomy, because of the danger of persistent urinary fistula. If for any reason the pelvis of the kidney is to be opened, he recommends the insertion of drainage retrograde from parenchyma to pelvis; but in instances when the pelvis of the kidney is not to be or cannot readily be opened, as in intrarenal pelvis, he favors the small nephrostomy without complete mobilization of the kidney. This technic has the advantage of a smaller skin incision and in general is less traumatic to the patient. This reviewer has seen this operation a number of times and has never been convinced that the drainage, whether by Pezzar catheter or other means, has been accurately placed, and has never used this technic, although well qualified surgeons in this country use it.

In discussion of pyelotomy or nephrotomy he naturally recommends the former whenever possible.. Where both are required, when possible the combined incisions should be low so that drainage from the kidney will be to the best advantage. Heminephrectomy and resection of a calyx are looked on as they are in this country.

In general, this monograph is well worth reading if one is thoroughly familiar with German medical style and language. The use of words and the style are rather involved and heavy. The forty illustrations are instructive, especially the roentgenograms.

**The Driving Forces of Human Nature and Their Adjustment: An Introduction to the Psychology and Psychopathology of Emotional Behavior and Volitional Control.** By Dom Thomas Verner Moore, Ph.D., M.D. Fabrikoid. Price, $6.50. Pp. 461, with 26 illustrations. Grune & Stratton, Inc., 381 Fourth Ave., New York 16, 1948.

Dom Thomas Verner Moore is known for his scholarly productions in psychopathology. Moore has an intense interest in vector analysis, which is a statistical procedure used in psychology to determine constellations of traits or syndromes which are found in certain spheres of abnormal psychology. Most of these syndromes represent clinical syndromes, but are defined in new terms. Nevertheless their identification from the description of single traits with the current terminology is not difficult. One must remember too that Father Moore is known for an effective dilution of freudian psychology. In the present volume he has adequately and acceptably gone through the narrow channel between the Scylla of the Catholic Church's attitude at that time toward psychonalysis and the Charybdis of orthodox freudian psychology. The present volume is a complete clinical survey of the application of his own beliefs toward the psychoneuroses, their development and expression with some emphasis on the psychosomatic aspect of the psychoneuroses and with some discussion of child guidance.

If one has sufficient background to evaluate the deviations of Moore's thinking from accepted psychiatric thought, the book should be a valuable asset in developing his thinking in terms of breadth. One must hesitate to recommend this volume as material for a beginner in the field of psychopathology.

**Toxoplasmosis: A Clinical, Serological and Histopathological Study with Special Reference to the Eye Manifestations. Presentation of Twenty Cases of Proved or Presumable Toxoplasmic Retinopathy and Retino-Encephalopathy with Associated Ocular Manifestations.** By Dr. C. D. Binkhorst. Cloth. Price, $3.75. Pp. 163, with 20 illustrations. H. E. Stenfert Kroese's Uitgevers-Mij N.V., Leiden, Netherlands, 1948.

This monograph on toxoplasmosis covers the field mentioned in the long title. It gives a comprehensive review of the existent knowledge of the subject divided into the usual scheme of epidemiology, immunology, histopathology, clinical aspects, diagnosis and treatment. Sulfonamide compounds have slight therapeutic effect in experimentally infected animals; penicillin has no effect, and streptomycin and chloramphenicol apparently have not yet been tested. There is a brief summary of the 49 cases thus far reported, including 20 of the author's, with detailed discussion of ocular changes.

The serologic studies reported are not reliable, being based on old technic which has since been improved. The clinical and pathologic descriptions and the illustrations are excellent. Here and there are slight deviations from conventional English, indicating foreign authorship, which adds a degree of charm to the opus.

# Queries and Minor Notes

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

## ISOLATION PERIODS IN COMMUNICABLE DISEASE

*To the Editor:*—What is the latest information on length of quarantine for measles, mumps, chickenpox, whooping cough, scarlet fever and diphtheria? What are the reasons for changing the old periods of quarantine?

M.D., Ohio.

Answer.—Rigid quarantine regulations are seldom required for the diseases mentioned. However, customary isolation periods are as follows: (1) measles, from the onset of illness until the rash has disappeared; in uncomplicated cases this generally means about ten days; (2) mumps, until all swelling of the parotid glands has subsided, or eight days from the onset of illness; (3) chickenpox, fourteen days, or until the body is free of all crusts; however, the American Public Health Association has expressed the opinion that varicella is not contagious six days after the appearance of the first lesions, regardless of any crusts that may persist; (4) whooping cough, until three weeks after the beginning of the paroxysmal stage; (5) scarlet fever, a minimum period of fourteen days, but a continuation of isolation if there are abnormal discharges; if the latter persist, until forty-five days, when negative nose and throat cultures for hemolytic streptococci should be secured before the patient is released; (6) diphtheria, minimum, seven days, or at any time after that when two successive cultures from nose and throat, taken not less than twenty-four hours apart, are negative for diphtheria bacilli.

Isolation periods are not the same in all states, and consequently the information supplied may be in conformity with public health regulations in one locality but not in another. For some years the American Public Health Association has worked for uniform requirements throughout the country. Changes in isolation periods which are adopted from time to time are based on scientific progress concerning the nature of the acute infectious diseases.

## DIAPHRAGMATIC HERNIA IN PREGNANCY

*To the Editor:*—A young woman has a diaphragmatic hernia (discovered on a physical examination for entering nurses' training). She passed the physical examination satisfactorily, but roentgen rays showed the hernia. She has been advised to have the hernia repaired before getting pregnant.

W. A. Dean, M.D., Tulsa, Okla.

Answer.—There are several factors involved in this problem. One wonders how this hernia was picked up by "routine" roentgen examination unless either the patient complained of symptoms or the hernia was extensive enough to show by flat plate. These hernias are frequently missed by so-called routine studies and are sometimes difficult to demonstrate with barium examination.

If the hernia is asymptomatic or merely a defect in the diaphragm then it probably is of only academic interest and the patient should merely be informed of its presence in case of future trouble.

If the hernia is symptomatic or abdominal viscera are present in the chest cavity then the hernia should be repaired now.

The only effect of pregnancy would be to increase the intra-abdominal pressure and the relaxation of the abdominal wall frequently takes care of this. If the hernia causes symptoms during pregnancy, it can be repaired then.

## USE OF LIVER PREPARATIONS

*To the Editor:*—Please furnish information about the proper use of liver extracts parenterally. It is not uncommon to see patients treated for hypochromic anemia with U. S. P. 15 unit liver extract solution. The detail men tell me that I am doing wrong by using crude liver extract in such cases! Recently when asking for a ½ unit crude liver extract I was told to take a two unit liver, dilute it four fold and use it!

Anthony M. Susinno, M.D., Palisades Park, N. J.

Answer.—Crude extracts of liver are still considered by some authorities to be superior to highly refined preparations for the treatment of spinal cord changes incident to addisonian pernicious anemia. Because it was considered likely that too highly refined and concentrated extracts for injection might omit some, as yet unknown, important principle which may form a part of what is called the antipernicious anemia factor, the U. S. Pharmacopeia Anti-Anemia Preparations Advisory Board has limited the concentration of parenteral liver extract to a maximum of 15 U. S. P. injectable units per cubic centimeter of the finished solution. Most pharmaceutical manufacturers prepare other lesser concentrations of liver extract by dilution of a more concentrated preparation, so that a solution for injection labeled to contain 2 U. S. P. injectable units does not necessarily represent a more "crude" preparation as implied by the lesser concentration. The U. S. Pharmacopeia, however, provides for crude preparations having not more than 2 U. S. P. injectable units per cubic centimeter that are permitted to be labeled as liver injection (crude) when prepared, so that the final product is directly derived from a solution having an alcohol concentration not higher than 70 per cent by volume. Crude extracts labeled as such are usually not available in concentration less than 1 U. S. P. injectable unit per cubic centimeter. Undiluted extracts are thus distinguished from diluted products of the same concentration by the label designation indicated.

The choice between "crude" and "refined" products for the treatment or prevention of neurologic complications of pernicious anemia is still the subject of some controversy, but it is now usually conceded that all extracts which conform to U. S. P. requirements are approximately equal in their ability to prevent or reverse these manifestations of the disease. The diluted preparations should not therefore be viewed so much in the light of inferiority as from the standpoint of suitable concentration to permit adequate maintenance dosage. This should provide not less than the equivalent of 1 U. S. P. unit (oral or injectable, depending on the mode of administration of the product) daily. The minimum recommended dosage can be given as 15 U. S. P. units twice a month with less inconvenience than with lesser doses at shorter intervals, once the disease is brought under control.

Liver extract is ordinarily indicated for treatment of hyperchromic macrocytic anemia rather than for hypochromic microcytic anemia.

## LICHEN PLANUS

*To the Editor:*—A male patient aged 59 is suffering with lichen planus distributed over the entire body, including all extremities, since July 1948. Despite adequate treatment with bismuth compound, and iron, and roentgen therapy, the eruption has progressed with short remissions. The patient has considerable pruritus. Can you suggest anything that might benefit this patient?

Joseph Burns, M.D., Miami Beach, Fla.

Answer.—The use of calciferol (vitamin $D_2$) has recently been recommended for the treatment of lichen planus, but experience with it is still limited. The dosage presumably is the same as for lupus vulgaris; i. e., 50,000 units two or three times daily. The calcium level of the blood serum must be checked at frequent intervals. Most physicians still rely on a combination of rest and relaxation, both mental and physical; the use of heavy metals, as bismuth, mercury or arsenic, and sometimes liver extract. Bismuth sodium triglycollamate, an oral preparation of bismuth, one to two tablets three times a day for four to six weeks, has some enthusiastic advocates. In addition, it is well for the patient to use antipruritic lotions or ointments.

## INSTABILITY IN DIABETES

*To the Editor:*—A woman, aged 34, has been under treatment for diabetes for twenty-four years. At the present time she takes 40 units of globin insulin in the morning and is on a 1,600 calory diet. She is sugar free before breakfast. Before the noon meal her sugar varies from none to 3 or 4 plus. On alternate afternoons she will be sugar free with many episodes of hypoglycemia coming on between four and six o'clock in the evening. Other afternoons the sugar content runs from 1 to 4 plus. An internist she has consulted maintains that she should keep herself sugar free at all times. Her health is otherwise good, and even when hospitalized she reacts the same way. Can you offer suggestions as to the management of this case?

H. V. Temple, M.D., Moab, Utah.

Answer.—In occasional cases complete control of glycosuria is obtainable only at the risk of episodes of hypoglycemia, and in such cases it sometimes is desirable to permit some glycosuria, especially at noon and in the evening, provided always that morning urine is sugar free. When globin insulin is used it sometimes is desirable to give a dose of regular insulin in the morning and inject the globin insulin at noon. The action of globin insulin in most cases is shorter than twenty-four hours, and by the procedure suggested quick action is obtained in the morning when it is needed most and the dose of globin insulin given can be smaller. In the case described I suggest a

Public health workers hope through the World Health Organization an almost singular example of international cooperation in sharing of knowledge, personnel and equipment, to see at last a world united.

**Handbook of Midwifery.** By Marageret Puxon, M.D., M.R.C.O.G., Obstetric Consultant, Essex County Council, Essex, England. Cloth. Price, 25s. Pp. 326. Sylviro Publications, Ltd., 19 Welbeck Street, London, W.1, 1949.

This handbook is well written and covers the subject adequately. Evidently, English physicians need such a work, for the author states, "Unfortunately, the increase in antenatal care in this country has so far tended towards excessive interference, so that the stillbirth and neonatal rates remain high, in contrast to the remarkable improvement in maternal mortality in recent years."

The author stresses the use of analgesia in the first stage of labor, especially the use of meperidine hydrochloride in 100 mg. doses. After delivery, leg exercises are begun on the second day. Early rising is not recommended except in patients who have not had perineal repairs. A fourteen day stay in the hospital is recommended.

The chapter on the Rh factor in obstetrics is particularly well written, stating the known facts in an orderly fashion. The advice not to employ version in occipitoposterior positions is open to argument, especially when it is advised for face presentations. Throughout the book the author warns the physician to be on the lookout for shock and postpartum hemorrhage.

The low cervical cesarean section is recommended in preference to the classic. Interrupted nylon® sutures are used to close the wound in the lower uterine segment. No mention is made of the Portes cesarean section in cases of infection. The use of the cesarean section is broadened, and it is recommended for suspected difficult deliveries throughout the book. Unfortunately, symphysiotomy is still recommended.

The chapter on the treatment of immediate partum hemorrhage recommends the hot douche for its control. Also the use of ergonovine maleate injected directly into the uterus through the abdominal wall is stressed, and packing the uterus is recommended as a last resort.

This book is recommended to those who wish a quick résumé as an aid in the care of the obstetric patient.

**Die beiderseitige Nierensteinkrankheit.** Von Dozent Dr. Bertrand Bibus. Band III, Wiener Beiträge zur Urologie. Herausgegeben von Prof. Dr. Richard Übelhör. Boards. Price, $6. Pp. 169, with 40 illustrations. Wilhelm Maudrich, Spitalgasse 1B, Wien IX/2; imported by Grune & Stratton, Inc., 381 Fourth Ave., New York 16, 1948.

This small book devoted to a discussion of bilaterally occurring renal calculi is well prepared. Other monographs in the series are by Drs. Hutter, Glingar and Hyrutschak, all well known contributors to urologic literature, and these monographs are edited by Prof. Lorenz Übelhör. This volume is divided into three parts. First there is a general discussion of the subject, under which etiology, chemistry, course of the disease and its complications, its association with other complicating diseases of the kidneys and roentgen diagnosis are thoroughly considered. The second part is devoted to conservative or nonoperative treatment and the third part to operative therapy. The usual important divisions are made, and there are nine pages devoted to stone in a solitary kidney. Bibus states as definite indications for surgical attack on a stone-bearing solitary kidney: First, colic and hematuria of such degree and so harmful to the patient that the risk of operation is of secondary consequence. Second, recurrent anuria due to stone in an uninfected kidney, even if the immediate anuria can be overcome by ureteral catheterization. He correctly states that repeated instrumentation usually leads to infection and the patient is thereby subjected to added danger. Third, not only the actual complete obstruction produced by a stone in a solitary kidney, but the apparent likelihood or imminence of such a complication. Fourth, acute onset of infection of the kidney or in the perirenal tissues. Fifth, acute anuria produced by stone. As his sixth indication, he says that the decision to operate on a person in a chronic suburemic state is a difficult one, and he elaborates on the age and general status of the patient as being of great importance in the final decision.

Under general considerations of operative technic, he conforms with generally accepted procedures. For example, he does not favor pyelostomy as against nephrostomy, because of the danger of persistent urinary fistula. If for any reason the pelvis of the kidney is to be opened, he recommends the insertion of drainage retrograde from parenchyma to pelvis; but in instances when the pelvis of the kidney is not to be or cannot readily be opened, as in intrarenal pelvis, he favors the small nephrostomy without complete mobilization of the kidney. This technic has the advantage of a smaller skin incision and in general is less traumatic to the patient. This reviewer has seen this operation a number of times and has never been convinced that the drainage, whether by Pezzar catheter or other means, has been accurately placed, and has never used this technic, although well qualified surgeons in this country use it.

In discussion of pyelotomy or nephrotomy he naturally recommends the former whenever possible. Where both are required, when possible the combined incisions should be low so that drainage from the kidney will be to the best advantage. Heminephrectomy and resection of a calyx are looked on as they are in this country.

In general, this monograph is well worth reading if one is thoroughly familiar with German medical style and language. The use of words and the style are rather involved and heavy. The forty illustrations are instructive, especially the roentgenograms.

**The Driving Forces of Human Nature and Their Adjustment: An Introduction to the Psychology and Psychopathology of Emotional Behavior and Volitional Control.** By Dom Thomas Verner Moore, Ph.D., M.D. Fabrikoid. Price, $6.50. Pp. 461, with 26 illustrations. Grune & Stratton, Inc., 381 Fourth Ave., New York 16, 1948.

Dom Thomas Verner Moore is known for his scholarly productions in psychopathology. Moore has an intense interest in vector analysis, which is a statistical procedure used in psychology to determine constellations of traits or syndromes which are found in certain spheres of abnormal psychology. Most of these syndromes represent clinical syndromes, but are defined in new terms. Nevertheless their identification from the description of single traits with the current terminology is not difficult. One must remember too that Father Moore is known for an effective dilution of freudian psychology. In the present volume he has adequately and acceptably gone through the narrow channel between the Scylla of the Catholic Church's attitude at that time toward psychonalysis and the Charybdis of orthodox freudian psychology. The present volume is a complete clinical survey of the application of his own beliefs toward the psychoneuroses, their development and expression with some emphasis on the psychosomatic aspect of the psychoneuroses and with some discussion of child guidance.

If one has sufficient background to evaluate the deviations of Moore's thinking from accepted psychiatric thought, the book should be a valuable asset in developing his thinking in terms of breadth. One must hesitate to recommend this volume as material for a beginner in the field of psychopathology.

**Toxoplasmosis: A Clinical, Serological and Histopathological Study with Special Reference to the Eye Manifestations. Presentation of Twenty Cases of Proved or Presumable Toxoplasmic Retinopathy and Retino-Encephalopathy with Associated Ocular Manifestations.** By Dr. C. D. Binkhorst. Cloth. Price, $3.75. Pp. 163, with 20 illustrations. H. E. Stenfert Kroese's Uitgevers-Mij N.V., Leiden, Netherlands, 1948.

This monograph on toxoplasmosis covers the field mentioned in the long title. It gives a comprehensive review of the existent knowledge of the subject divided into the usual scheme of epidemiology, immunology, histopathology, clinical aspects, diagnosis and treatment. Sulfonamide compounds have slight therapeutic effect in experimentally infected animals; penicillin has no effect, and streptomycin and chloramphenicol apparently have not yet been tested. There is a brief summary of the 49 cases thus far reported, including 20 of the author's, with detailed discussion of ocular changes.

The serologic studies reported are not reliable, being based on old technic which has since been improved. The clinical and pathologic descriptions and the illustrations are excellent. Here and there are slight deviations from conventional English, indicating foreign authorship, which adds a degree of charm to the opus.

# Queries and Minor Notes

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

## ISOLATION PERIODS IN COMMUNICABLE DISEASE

**To the Editor:**—What is the latest information on length of quarantine for measles, mumps, chickenpox, whooping cough, scarlet fever and diphtheria? What are the reasons for changing the old periods of quarantine?

M.D., Ohio.

Answer.—Rigid quarantine regulations are seldom required for the diseases mentioned. However, customary isolation periods are as follows: (1) measles, from the onset of illness until the rash has disappeared; in uncomplicated cases this generally means about ten days; (2) mumps, until all swelling of the parotid glands has subsided, or eight days from the onset of illness; (3) chickenpox, fourteen days, or until the body is free of all crusts; however, the American Public Health Association has expressed the opinion that varicella is not contagious six days after the appearance of the first lesions, regardless of any crusts that may persist; (4) whooping cough, until three weeks after the beginning of the paroxysmal stage; (5) scarlet fever, a minimum period of fourteen days, but a continuation of isolation if there are abnormal discharges; if the latter persist, until forty-five days, when negative nose and throat cultures for hemolytic streptococci should be secured before the patient is released; (6) diphtheria, minimum, seven days, or at any time after that when two successive cultures from nose and throat, taken not less than twenty-four hours apart, are negative for diphtheria bacilli.

Isolation periods are not the same in all states, and consequently the information supplied may be in conformity with public health regulations in one locality but not in another. For some years the American Public Health Association has worked for uniform requirements throughout the country. Changes in isolation periods which are adopted from time to time are based on scientific progress concerning the nature of the acute infectious diseases.

## DIAPHRAGMATIC HERNIA IN PREGNANCY

**To the Editor:**—A young woman has a diaphragmatic hernia (discovered on a physical examination for entering nurses' training). She passed the physical examination satisfactorily, but roentgen rays showed the hernia. She has been advised to have the hernia repaired before getting pregnant.

W. A. Dean, M.D., Tulsa, Okla.

Answer.—There are several factors involved in this problem. One wonders how this hernia was picked up by "routine" roentgen examination unless either the patient complained of symptoms or the hernia was extensive enough to show by flat plate. These hernias are frequently missed by so-called routine studies and are sometimes difficult to demonstrate with barium examination.

If the hernia is asymptomatic or merely a defect in the diaphragm then it probably is of only academic interest and the patient should merely be informed of its presence in case of future trouble.

If the hernia is symptomatic or abdominal viscera are present in the chest cavity then the hernia should be repaired now.

The only effect of pregnancy would be to increase the intra-abdominal pressure and the relaxation of the abdominal wall frequently takes care of this. If the hernia causes symptoms during pregnancy, it can be repaired then.

## USE OF LIVER PREPARATIONS

**To the Editor:**—Please furnish information about the proper use of liver extracts parenterally. It is not uncommon to see patients treated for hypochromic anemia with U. S. P. 15 unit liver extract solution. The detail men tell me that I am doing wrong by using crude liver extract in such cases! Recently when asking for a ½ unit crude liver extract I was told to take a two unit liver, dilute it four fold and use it!

Anthony M. Susinna, M.D., Palisades Park, N. J.

Answer.—Crude extracts of liver are still considered by some authorities to be superior to highly refined preparations for the treatment of spinal cord changes incident to addisonian pernicious anemia. Because it was considered likely that too highly refined and concentrated extracts for injection might omit some, as yet unknown, important principle which may form a part of what is called the antipernicious anemia factor, the U. S. Pharmacopeia Anti-Anemia Preparations Advisory Board has limited the concentration of parenteral liver extract to a maximum of 15 U. S. P. injectable units per cubic centimeter of the finished solution. Most pharmaceutical manufacturers prepare other lesser concentrations of liver extract by dilution of a more concentrated preparation, so that a solution for injection labeled to contain 2 U. S. P. injectable units does not necessarily represent a more "crude" preparation as implied by the lesser concentration. The U. S. Pharmacopeia, however, provides for crude preparations having not more than 2 U. S. P. injectable units per cubic centimeter that are permitted to be labeled as liver injection (crude) when prepared, so that the final product is directly derived from a solution having an alcohol concentration not higher than 70 per cent by volume. Crude extracts labeled as such are usually not available in concentration less than 1 U. S. P. injectable unit per cubic centimeter. Undiluted extracts are thus distinguished from diluted products of the same concentration by the label designation indicated.

The choice between "crude" and "refined" products for the treatment or prevention of neurologic complications of pernicious anemia is still the subject of some controversy, but it is now usually conceded that all extracts which conform to U. S. P. requirements are approximately equal in their ability to prevent or reverse these manifestations of the disease. The diluted preparations should not therefore be viewed so much in the light of inferiority as from the standpoint of suitable concentration to permit adequate maintenance dosage. This should provide not less than the equivalent of 1 U. S. P. unit (oral or injectable, depending on the mode of administration of the product) daily. The minimum recommended dosage can be given as 15 U. S. P. units twice a month with less inconvenience than with lesser doses at shorter intervals, once the disease is brought under control.

Liver extract is ordinarily indicated for treatment of hyperchromic macrocytic anemia rather than for hypochromic microcytic anemia.

## LICHEN PLANUS

**To the Editor:**—A male patient aged 59 is suffering with lichen planus distributed over the entire body, including all extremities, since July 1948. Despite adequate treatment with bismuth compound, and iron, and roentgen therapy, the eruption has progressed with short remissions. The patient has considerable pruritus. Can you suggest anything that might benefit this patient?

Joseph Burns, M.D., Miami Beach, Fla.

Answer.—The use of calciferol (vitamin $D_2$) has recently been recommended for the treatment of lichen planus, but experience with it is still limited. The dosage presumably is the same as for lupus vulgaris; i. e., 50,000 units two or three times daily. The calcium level of the blood serum must be checked at frequent intervals. Most physicians still rely on a combination of rest and relaxation, both mental and physical; the use of heavy metals, as bismuth, mercury or arsenic, and sometimes liver extract. Bismuth sodium triglycollamate, an oral preparation of bismuth, one to two tablets three times a day for four to six weeks, has some enthusiastic advocates. In addition, it is well for the patient to use antipruritic lotions or ointments.

## INSTABILITY IN DIABETES

**To the Editor:**—A woman, aged 34, has been under treatment for diabetes for twenty-four years. At the present time she takes 40 units of globin insulin in the morning and is on a 1,600 calory diet. She is sugar free before breakfast. Before the noon meal her sugar varies from none to 3 or 4 plus. On alternate afternoons she will be sugar free with many episodes of hypoglycemia coming on between four and six o'clock in the evening. Other afternoons the sugar content runs from 1 to 4 plus. An internist she has consulted maintains that she should keep herself sugar free at all times. Her health is otherwise good, and even when hospitalized she reacts the same way. Can you offer suggestions as to the management of this case?

H. V. Temple, M.D., Moab, Utah.

Answer.—In occasional cases complete control of glycosuria is obtainable only at the risk of episodes of hypoglycemia, and in such cases it sometimes is desirable to permit some glycosuria, especially at noon and in the evening, provided always that morning urine is sugar free. When globin insulin is used it sometimes is desirable to give a dose of regular insulin in the morning and inject the globin insulin at noon. The action of globin insulin in most cases is shorter than twenty-four hours, and by the procedure suggested quick action is obtained in the morning when it is needed most and the dose of globin insulin given can be smaller. In the case described I suggest a trial of the effect of 20 units of regular insulin before breakfast, followed by an injection of 20 units of globin insulin before the noon meal.

The causes of the instability in such cases of diabetes are probably many. Frequently they cannot be explained. In many cases instability seems to depend not so much on the utilization of glucose as on instability of hepatic glycogen.

## SENSITIVITY TO RUBBER NIPPLES

**To the Editor:**—An infant's oral tissues are sensitive to rubber nipples to the extent that the mouth and tongue swell and become inflamed. Does any one manufacture a nipple of a substance other than rubber?

M.D., New York.

ANSWER.—It is improbable that the rubber itself or latex from which the nipple is made is causing the irritation in this infant; more probably, if the irritation is due to the nipple it is from some chemical used in the molding or formation of the latex into the form of the nipple. A dermatitis has been described by Schwartz of the United States Public Health Service among laborers wearing rubber gloves in the tanning industry. In this instance it was shown that it was not the rubber latex of the gloves which caused the dermatitis, but certain chemicals used in the manufacture of the rubber gloves. It would seem worth while to inquire into the chemicals used in the manufacture of rubber nipples and perhaps by skin tests ascertain which chemical might be causing the symptoms in this baby. If this could be easily ascertained a rubber nipple might be selected from a firm that did not use this chemical in the manufacture of their nipples.

Before the advent of rubber nipples or glass bottles in the early centuries, such contrivances as small horns with parchment nipples were used, as well as jugs, cans or cups with spouts made of wood, earthenware, tin and other materials. These were used down to the eighteenth and nineteenth centuries, when glass and rubber nipples first came into use.

As far as is known present day nipples are all made of rubber latex. Use of a glass medicine dropper or teaching the infant to drink from a spoon, small glass or cup might solve this problem.

## SUTURE OF PILLARS AFTER TONSILLECTOMY

**To the Editor:**—I have observed a surgeon suture the anterior pillar to the posterior pillar after tonsillectomy, in order to prevent postoperative hemorrhage. Is this considered good procedure?

Paul Russell, M.D., Inglewood, Calif.

ANSWER.—Suturing of the anterior and posterior pillars for the prevention of hemorrhage after tonsillectomy is not a generally accepted procedure among otolaryngologists. It is recommended instead that there be careful inspection of the tonsil fossae for any bleeding areas or vessels. The bleeding points may then be grasped with long artery forceps and a ligature applied by one of several methods. The tonsil pillars contain specialized muscle groups, the names of which denote their origin and attachment. The palatoglossus muscle lies in the anterior pillar; the posterior pillar includes the palatopharyngeus muscle. The latter is the more important but both are concerned with deglutition and, indirectly, with phonation. Respect for these structures is mandatory in a well performed tonsillectomy. Suturing of the pillars together renders them liable to inclusion in the scar tissue laid down during the healing process, with resultant swallowing or phonatory dysfunction. Furthermore, bleeding may occur despite the suturing of the pillars, in which case the blood may dissect either into the soft palate or into the deep cervical fascial spaces, adding still further complications.

## CHANGE OF CLIMATE IN RECURRENT OTITIS

**To the Editor:**—What is the therapeutic value of change of climate in relationship to hearing in a 5 year old child who apparently has allergic tendencies and asthma? This child lives in Oklahoma and has been advised to move to New Mexico or Arizona. What is your opinion on the results of irradiation of the nose and throat with radium?

J. M. Hesser, M.D., Benson, Ariz.

ANSWER.—If the hearing loss is primarily of the auditory nerve or perception type, no change in climate is apt to do any good. If the deafness is of the conduction or middle ear variety and due to frequent attacks of otitis media, then a change to another climate may be of considerable benefit, in certain circumstances.

If it is to work, the removal to another area must result in elimination of the offending allergens. The best example would be in cases of allergy due to pollen present in the home area but absent in another locale.

Improvement of allergy may often result in a diminution in the number and severity of head colds, for these are increased in number and protracted in the person suffering from nasal allergies. Middle ear involvement is seen often in children of this type, and the course of the deafness is further prolonged by the necessary use of antibiotics and sulfonamide compounds in combating the infection. The antibiotics prevent or modify suppurative otitis media and its complications, but their use often results in the appearance of an exudative catarrh which causes considerable deafness and, for weeks after, acute otitis.

Results of irradiation of the nose and throat with radium or roentgen rays are not easily evaluated. If irradiation is used to reduce the number of infections or mechanical obstruction due to lymphoid tissue there is good reason to believe that, in a fair number of cases, considerable improvement is obtained. Like any other therapeutic measure, the results are open to differences in interpretation. Those who use it in conjunction with operation, either before or after, are of the opinion that many persons, especially young children, are so improved that radiation is an agent well worth using empirically. After the passage of time, the effects of radiation therapy wear off. In this event careful retreatment may again offer improvement.

## NASAL IRRIGATION

**To the Editor:**—I am bothered by nasal obstruction whenever I have a cold. When I was in the Army, an otolaryngologist irrigated my nose with a hypertonic or hypotonic solution of either dextrose or sodium chloride. This is the only thing which has ever given me relief without causing an increased congestion after the effects wore off. Are there any methods of relieving nasal congestion which do not cause increased congestion? Does a chloretone® (chlorobutanol) solution have this effect?

W. R. Cohlan, M.D., North Fork, Calif.

ANSWER.—As a general rule, it is not advisable to use nasal irrigation for the relief of nasal obstruction. In exceptional cases an irrigation may be employed to remove thick secretions which the patient is unable to expel. When the nose is irrigated frequently, there is a tendency to a waterlogging of the tissues which impairs their functional capacity and leads to an edematous state. Furthermore, the introduction of a large amount of fluid into the nose may lead to the removal of the mucus blanket which covers the ciliated epithelium and is one of the primary elements in the normal defense mechanism of the nose. A saline irrigation affords temporary relief; repetition may lead to secondary engorgement and stasis. So far as the chlorobutanol solution is concerned, the relief experienced by the patient is in fact an illusion, the same as is experienced after the use of menthol and thymol. In other words, these drugs cause a mild degree of anesthesia which imparts the sensation of increased breathing space.

The safest and simplest method of relieving nasal congestion in an acute rhinitis is to use ephedrine 1 per cent in isotonic sodium chloride solution or to take ephedrine hydrochloride, grain 3/8 (25 mg.) by mouth three or four times daily.

At times an underlying allergy may be a factor, in which case relief may be had from the antihistaminics.

## SPONTANEOUS PNEUMOTHORAX

**To the Editor:**—The query concerning spontaneous pneumothorax (The Journal, January 1, p. 69) suggests the following comments:

The diagnosis of recurrent spontaneous pneumothorax has apparently not been proved, since it is stated that roentgen examination showed partial collapse on the last occasion and it is implied that roentgenograms were not made on the five previous occasions. Also the physical examination was negative in result, and usually the physical examination reveals clearcut signs unless the collapse is extremely slight, in which case the symptoms and period of convalescence necessary would be of short duration, or unless the lungs are already partly adherent. In cases in which roentgen and clinical findings suggest recurrent spontaneous pneumothorax and an adequate air-filled pleural space exists, the next logical step in diagnosis is thoracoscopy. This may reveal an adhesion with a tear in the lung near its visceral attachment which acts as a valve and prevents reexpansion, or it may reveal a large cystic space which actually represents the interior of an inflated lung cyst, in which case some form of pulmonary cystic disease is the cause. Other evidence of pleural disease may be discovered. Such a case was reported by Theodos (*Dis. of Chest* 14:115, 1948) in which cystic changes were limited to the right lower lobe and cure was achieved by lobectomy (Willauer).

The treatment of spontaneous pneumothorax depends on its cause, and without accurate diagnosis it is just as dangerous to treat this condition as any other disease. Thus talc insufflation (Steele), suggested in the answer, would prove hazardous in those conditions mentioned in which the talc might gain access to the lung. Talc insufflation should never be done without careful inspection of the visceral pleura thoracoscopically. The improvement of diagnostic methods and increased skill in their application will narrow the already rare indications for the production of pleural symphysis with talc or by any other method.

# CONGESTIVE HEART FAILURE

## Adaptation of the Body to Inadequate Cardiac Output

WILLIAM DOCK, M.D.
Brooklyn

Until early in the nineteenth century physicians considered dropsy as a disease in itself, much as our generation deals with hypertensive cardiovascular disease. When renal, cardiac and hepatic diseases were defined, edema became merely a symptom. Starling pointed out that rise in venous pressure or fall in plasma protein would have similar effects in shifting fluid from the blood stream to the tissue spaces, and for several decades this explanation seemed to cover all cases of dropsy. High venous pressure was thought to underly the dyspnea, the proteinuria and the hepatic changes characteristic of heart failure. MacKenzie and Lewis were almost alone in their assumption that when the heart muscle failed the body would not receive its usual blood supply and that fatigue and dyspnea were due to anoxic metabolism. This view was given emphasis in Altschule's critical study [1] of heart failure. There the lack of correlation between symptoms and the elevation of venous pressure was noted.

In 1941 Borst, of Amsterdam, the Netherlands, in reporting the electrolyte retention which follows gastric hemorrhage, pointed out that in all forms of dropsy there were circulatory disturbances similar to those in hemorrhage, shock or dehydration.[2] He concluded that salt and water retention were secondary to inadequate cardiac output and that excretion of urine with a low sodium content in patients with congestive heart failure was one of the essential proofs that failure to maintain the proper output was present in this condition. This work was not known to Stead and his colleagues when they developed the view that cardiac edema was due to reduced volume of glomerular filtrate and was reflexly brought about by an inadequate blood supply to the tissues.[3] The existence of such a reflex mechanism had been proved by the classic studies of Homer Smith on renal blood flow.[4] Such a mechanism also operates in hypoproteinemia, and along with it increased desoxycorticosterone action as shown by reduction in electrolyte content of the sweat as well as of the urine.[5] The salt content of sweat and urine both return to normal, as does the glomerular filtrate, when the blood volume is restored by injecting human albumin.

Hemorrhage and shock reduce cardiac output by diminishing the venous return. In heart failure, venous return is ample but the work done by the heart is not adequate to meet the needs of the body. Disease of the pericardium may embarrass diastolic filling of the heart, and disease of the myocardium may diminish effectiveness of systolic discharge. If either develops rapidly in a person otherwise normal, the minute volume flow of blood under basal conditions will be reduced, and signs and symptoms like those of shock may be recognized. If it occurs gradually in a person who has metabolic or other causes for high basal cardiac output, the actual basal output may be normal or high, and in the latter case pulse pressure, heart sounds and impulses also will be increased. As in the case of other systems, the indications of failure do not depend on the absolute amount of work the organ or system is doing, but on the ratio of work done to that necessary for homeostasis, for maintaining a normal internal environment under existing stresses. The cardiac output adequate for a starving man at rest would be wholly inadequate for a Peruvian miner carrying a pack up a ladder 17,000 feet above sea level.

### ADAPTATION TO CIRCULATORY FAILURE

When the cardiac output drops rapidly from an adequate to an inadequate level, whether because of shock, hemorrhage, pericardial tamponade, extreme tachycardia, acute myocardial failure or acute obstruction to systolic emptying, the symptoms are the same. Loss of consciousness, particularly if erect or sitting; pallor, cold sweat, nausea, weakness and anuria are common to all these conditions, and death may occur suddenly. Gasping respiration is not uncommon. Systemic venous pressure may be within the normal range, or low in shock or slightly or moderately elevated in acute forms of cardiac disease. Diastolic arterial pressure may be low or normal, or even elevated, if the patient was hypertensive previously. The patient may feel well and even appear well if lying still, but

he becomes critically ill and has a drop in diastolic pressure, or he may even die, if exercise or the erect posture is attempted. Because the indications of acute cardiac failure and of shock are identical, and the venous pressure in either may be in the normal range, the differentiation often must be made on collateral evidence. This may be misleading, as when a patient being treated for peptic ulcer goes into shock and is assumed to be having internal hemorrhage but is later proved to have had a painless myocardial infarct. It is well to bear in mind that management must often begin without knowledge of the nature of the underlying condition, and that a confidently held diagnosis may prove erroneous in a case of acute circulatory collapse.

When shock or acute failure subsides into a subacute state, with the patient comfortable at rest but easily made dyspneic or giddy on effort, it is possible to demonstrate that a number of compensatory mechanisms are at work. After hemorrhage, hematic dilution and new formation of blood are striking; in heart failure, increase in the heart volume usually is demonstrable together with a rise in venous pressure and in total blood volume. In all these conditions the percentage decrease in renal blood flow is much greater than in cardiac output,[6] and the urine is scanty, highly concentrated but poor in sodium chloride. In all such patients splanchnic blood flow is decreased and hepatic venous oxygen tension is low.[7] These changes are observed in heart failure even when the basal cardiac output is high because of anemia or other causes. Another change common to all, but most striking in heart failure with severe anemia, is a rise in venomotor tone, shifting blood into the large veins and raising central venous pressure even when the total blood volume is low. Venomotor tone is controlled by the nervous system, and the high venous pressure in chronic heart failure falls promptly on the injection of sympathicolytic agents such as tetraethyl ammonium chloride.[8] The change peculiar to myocardial failure is an increase in ventricular volume (dilatation of the heart) and later, if the disorder persists for weeks or months, hypertrophy of the heart and great veins. Decrease in renal and splanchnic blood flow, rise in vasomotor tone, sodium and water retention and rise in blood volume—these adaptations occur in hemorrhage, acute or subacute shock, and in all types of heart failure, acute or chronic.

In the earlier stages of progressive myocardial failure patients show few or none of the signs and symptoms of acute circulatory collapse. They do have weakness or fatigability and have dyspnea on effort or after going to sleep in the recumbent position. Some of those who are dyspneic at night have excellent capacity for physical effort by day. Few persons with chronic cardiac disease are giddy in the erect position, because real discrepancy between cardiac output and the circulatory demands of the body occurs only in the severe or terminal phases of chronic or recurrent heart failure, whether due to pericardial or myocardial disease. Both these latter types are alike in signs and symptoms and can be distinguished only by careful study of the heart itself.

## CARDIAC BURDEN: EXTRINSIC FACTORS IN HEART FAILURE

Myocardial failure is due to myocardial fatigue and loss of efficiency, but it usually is seen associated with conditions which elevate the basal level of mechanical work performed by the ventricles. However, myocarditis, coronary insufficiency or infiltration by amyloid or glycogen may so impair the heart muscle that it fails to meet basal demands which are even less than normal. The burdens to be considered are (1) increase in rate, with shortening of the period of recovery, (2) increase in resistance to systolic ejection and (3) increase in stroke volume of blood being moved.

1. Increase in rate is usually observed in heart failure. It often is due to systemic infection, toxemia or other conditions which are in themselves bad for the heart. But in emotional tachycardias without hypertension, and in acute ectopic cardiac arrhythmias, occasion is afforded for observing how myocardial failure may be precipitated by accelerated rate alone. Many illnesses which confine patients to bed are followed by postural tachycardia which lasts for weeks or months. In such cases cardiac insufficiency may develop not during the acute illness but during convalescence. This is not uncommon after myocardial infarction and is one of the phenomena which has led some physicians to urge early assumption of the sitting posture and walking short distances on the level after recovery from the initial episode. A faster rate increases fuel and oxygen needs of the heart per minute, at constant levels of work. It shortens time available for recovery. As metabolic processes become slower with advancing age, heart failure is seen more often with any given degree of acceleration and after relatively short periods of acceleration. At ages under 25, cardiac insufficiency may not occur for days with an ectopic rhythm causing a rate of 200 or more; after the age of 50, failure is not uncommonly evident after a day or even a few hours with rates over 150.

2. Elevated systemic pressures up to twice the normal level and elevated pulmonic pressures up to four times the normal level, when developed slowly over months or years, are tolerated by the heart without evidence of dilatation or failure in the majority of instances. This is also true of aortic and pulmonic stenosis. Nevertheless, when hypertension develops rapidly or when it has been present for years or decades, dilatation and failure occur far oftener than with normal pressures. In mitral stenosis, auricular and pulmonary venous pressure rises on the left side first, pulmonary arterial pressure rising as a result of changes in the lungs. When failure occurs, right-sided dilatation with a rise in systemic venous pressure is often more striking than evidence of further rise in pulmonic venous pressure. In these cases pulmonic hypertension is of paramount importance as the burden which precipitates failure.

3. Elevated stroke volume is well tolerated for months or decades when it occurs in young persons and develops gradually. It may be present in fever, exophthalmic goiter, anemia, pregnancy, osteitis deformans and arteriovenous fistulas. It is seldom the only circulatory burden present when failure sets in, for in almost all cases acceleration of the heart rate is present, along with the increased volume flow. Because of rapid rate, stroke volume infrequently is significantly elevated in

heart failure except in the cases of valvular insufficiency or complete block. In all the aforementioned conditions the ventricle empties against low resistance, and the increase in burden on the muscle is not proportional to rise in the stroke volume. It must be remembered that the normal increase in stroke volume, occurring in exercise, is due to peripheral vasodilatation, with fall in diastolic pressure and arterial resistance. The great increase in minute volume of athletes under maximal stress occurs with no increase, and often an actual decrease, in heart volume. This is interpreted as meaning that myocardial effort per beat is not increased. Ventricular emptying is performed efficiently and ventricular diastolic and venous pressures are low. Even pulmonic resistance decreases during exercise, and right ventricular dilatation is not seen in the hearts of trained men doing maximal work, with pulmonary blood flow per minute five to eight times the basic rate. Yet in such men, the heart increases in size with the rise in output and arterial pressure which occurs for a short time on resumption of normal breathing after straining to expire against a closed glottis. We may conclude that the Valsalva experiment imposes greater burdens, of brief duration, than does moderate or even vigorous exercise, and that rise in diastolic pressure imposes a far greater burden on the heart than does a rise in stroke volume due to peripheral vasodilatation.

In summary, accelerated rate is usually present when the heart fails, elevated arterial resistance often is present, elevated stroke volume seldom. Rise in stroke volume due to increased need of the tissues for blood causes no great burden to the normal heart or that in early failure; rise in resistance to systolic emptying is well tolerated but does burden the heart; accelerated rate causes a proportional rise in cardiac metabolism and shortens the recovery period. In patients under 25 years of age, myocardial inflammation or infiltration is the usual cause of heart failure; in those over 35 years of age such a complication is present in less than half the cases, while abnormal burdens on the heart are commonly present. Some of these burdens can be reduced by treatment, and this may alleviate or entirely remove the signs and symptoms of heart failure. Failure to seek out such corrigible burdens is a cardinal sin for a physician.

When myocardial failure begins to develop, it necessarily results in decrease in efficiency of systolic emptying. Failure to empty is the cause of dilatation and of a rise in diastolic pressure within the ventricle. Even in severe cardiac insufficiency, ventricular filling takes place chiefly in the first half of diastole and auricular and ventricular pressures are approximately the same through the last half or two thirds of diastole. Thus the venous pressure is simply a reflexion of the diastolic pressure in the right ventricle. While rise in venous pressure and ventricular filling do augment systolic discharge, this usually falls below the requirements of the tissues for blood in all patients with symptoms of cardiac insufficiency. To maintain arterial pressure, vasoconstriction in various regions occurs and blood is shunted to the brain and the heart. While it is feasible to measure cardiac output and the fractions going to various regions, this is not necessary for clinical purposes. Useful clues to the degree of fall in the ratio of actual cardiac output to optimal cardiac output are given by the liver and the kidneys.

## EFFECTS OF LOW OUTPUT ON LIVER AND KIDNEYS

Using aromatic acid excretion and polysaccharide excretion as measures of renal blood flow and glomerular filtrate formation, it was shown by early students that the erect posture and exercise reduced renal flow and filtration, the latter falling much less than the former.[4] Later studies disclosed that violent exertion may reduce urine formation to zero for some minutes and be followed by oliguria and proteinuria. In shock, exercise and heart failure, reduction in renal blood flow, in urine formation and in sodium excretion are useful indexes of the decrease in adequacy of cardiac output. Rate of edema formation depends largely on the fall in ratio of excreted sodium to sodium ingested or injected, although when sodium ingested is low and excretion is forced by mercurial diuretics, water retention may exceed sodium retention, and the sodium content of blood and edema fluid may be lower than normal. In the patient with evidence of chronic cardiac disease, proteinuria which is not explained by a specific renal lesion and retention of administered salt may be taken as evidence of a definite fall in the ratio of actual to optimal cardiac output. Accurate measurements of renal blood flow and of cardiac output permit investigators to give some precision to the calculation of this ratio. When cardiac output is normal or high but renal filtrate or blood flow is reduced, either the kidney is the seat of local disease or optimal output must be extremely high.

Because renal metabolism, unique in this respect, declines with renal blood flow, no renal injury is sustained in shock of cardiac insufficiency unless the output of the heart is less than one-fifth optimal for many consecutive hours. The liver, however, does not reduce its metabolism when its blood supply is reduced. The cells at the centers of the lobules, where blood enters the radicles of the hepatic veins, are exposed to the lowest oxygen tensions and are the first to suffer when cardiac output becomes inadequate. But in shock the whole liver may be anoxic, and irreversible shock is associated with severe hepatic damage. When there are brief intermittent episodes of heart failure, hepatic cellular damage at the centers of lobules is repaired between bouts of failure and there are no signs of hepatic injury.

In chronic failure the central part of the lobe atrophies, and the lobule becomes a wall of parenchyma around a venous lake, which varies in size with the severity and duration of cardiac insufficiency. Fatty degeneration and interstitial edema affect even the periphery of the lobules when cardiac output is inadequate. This results in increased bulk and tenderness of the liver. In some instances aching pain may arise in the swollen liver. Thus, the state of the liver becomes another clue to the severity and duration of a decline in actual cardiac output in relation to optimal output. Hepatic disease may confuse the evidence, and anemia always accentuates hepatic damage in relation to decline in splanchnic flow. It is to be emphasized that rise in venous pressure, which is lowest at the center or outflow zone of the lobule, does not damage the liver. In heart failure and in cirrhosis of the liver venous pressure is high in glands like the pancreas, where venous pressure is always higher than in the liver, through which all the splanchnic venous blood flows. In spite of exceedingly high venous pressures, changes do not occur in gastrointestinal or pancreatic glands similar to those observed in the liver in cardiac failure. While hepatic damage is not due to high venous pressure, once the centers of lobules are changed to venous lakes hepatic volume increasingly reflects the levels of hematic volume and venous pressure.

### EDEMA AND DYSPNEA IN CARDIAC DISEASE

Shortness of breath is due to many factors. A decidedly important one is the responsiveness of the central nervous reflexes which control respiration. Many persons become short of breath, but actually overventilate their lungs, when they are emotionally disturbed. In its extreme form this is hysterical hyperpnea. Heart disease not infrequently occurs in patients with highly reactive breathing centers, and they are dyspneic with little organic disease. The sensitivity of the nerve endings in the lung is increased by inflammation or by sudden changes in the stiffness of the lung. Hence one observes dyspnea at rest at the onset of pneumonia, when only a small fraction of the lung is involved, and may encounter none in advanced tuberculosis. Edema of the lungs, or sudden rise in pulmonary venous pressure, may stiffen the lungs and make respiration rapid, shallow and inefficient. Both of these conditions also encroach on the air space in the lungs and reduce the vital capacity—the volume of air the patient can move with one maximal inspiratory and expiratory effort. Dyspnea is often minimal in young persons with mitral stenosis and exceedingly high pulmonic venous pressure. This leads one to conclude that pulmonary edema and sensitization of the respiratory reflexes due to inadequate supply of blood to the tissues of the body are the chief causes of cardiac dyspnea and of the dyspnea seen in shock and anemia.

Pulmonary edema, the chief factor in determining the urgency of cardiac dyspnea, is often a purely local manifestation of general anasarca. At times, however, pulmonary edema is pronounced although edema elsewhere in the body is not demonstrable. To understand these two types of pulmonary edema, and their endless intergradations and combinations, the main factors responsible for the localization of edema must be borne in mind. The thesis that edema is merely a resultant of high venous pressure and low serum protein is now known to be inadequate.

*Experimental Production of Edema.*—The simplest way to cause experimental edema is to abolish the pulse wave and perfuse the vessels with blood under a constant head of pressure. Lymph flow depends on the pulsation of the small vessels; it ceases and edema develops rapidly when pulsation is reduced or abolished.[9] Then venous pressure may be low and serum protein high, but edema forms quickly and inevitably. Vasoconstriction or arterial disease with resulting low pulse pressure predispose to edema formation. In thrombophlebitis of the leg edema formation is minimal, in spite of high venous pressures, unless there is arteriospasm. Relief of this spasm by paravertebral block may cause the edema to diminish greatly in a few hours, although venous pressure actually rises with the increase in arterial flow.[10]

In normal men and animals lymph flow ceases in a motionless dependent limb.[11] High venous pressure merely exaggerates the rate of edema formation in such dependent tissues. There is no general lymphostasis in patients with cardiac disease, even when venous pressure at the orifice of the thoracic duct is unusually high. When the legs have been edematous for long periods, the patient with cardiac disease may have dilated channels and incompetent valves in the lymphatic vessels of the edematous regions.[11b] When the leg is raised to the level of the heart as the subject lies down, flow in these channels is as rapid as that in the narrow lymphatic vessels of normal skin. The chief effect of increase in rate of tissue fluid formation, in cardiac disease or in hypoproteinemia, is to increase the rate of lymph flow.

The rate of fluid accumulation in the forearm when veins and lymphatics are occluded by a pneumatic cuff at 20 mm. of mercury is about equal to the lymph flow, per gram of tissue, from the heart or the lung of a dog under basal conditions.[12] At a venous pressure of 50 mm. of mercury fluid accumulates ten to twenty times as fast. In the dog, lowering plasma protein from 6.5 Gm. to 4 Gm. per hundred cubic centimeters raised the lymph flow sevenfold, and compression of the pulmonary veins until pulmonary arterial pressure was raised from 22 to 55 mm. of mercury raised lymph flow thirtyfold.[11a] These observations suggest that extra fluid formed in the tissues by rise in venous pressure can be rapidly returned to the blood stream via the lymphatic vessels. But in injured or dependent regions edema formation is hastened by high venous pressures.

Hemoconcentration is seen in acute cardiac failure only if the patient has become dehydrated. The blood volume either is normal in relation to the hemoglobin level in the patient with cardiac disease, or it is elevated. Renal function declines not because of but in spite of a high plasma volume, and on recovery renal function rises as blood volume falls. Thus, cardiac edema can never be explained in terms of high venous pressure, rapid formation of tissue fluid, extrarenal diversion of fluid or renal retention to restore blood volume.

The experiments of Wégria and his associates [13] with dogs show that rises in renal venous pressure between the limits of 15 and 40 cm. of water do not reduce renal blood flow or filtration rate, but as the venous pressure rises the rate of reabsorption of water and salt by the tubule increases. Pressure was raised only in the left renal vein, and the functions of the two kidneys were compared. A concentrated urine, low in sodium, came from the congested kidney. At levels of venous pressure around 30 cm. of water, salt and water excretion by the congested kidney was reduced as much as 50 per cent in these experiments with acute venous pressures. Therefore, rise in systemic venous pressure does augment the salt and water retention which is evoked by a fall in the ratio of actual cardiac output to optimal cardiac output, with reflex renal and endocrine adjustments similar to those in shock and with the low blood volume of hypoproteinemia. The mechanisms which evolution has perfected to deal with shock are not inhibited when cardiac output is impaired by heart failure, they are potentiated by rise in systemic venous pressure.

Until the body begins to store up water and salt, rise in venous pressure does not cause massive edema. When retention of water and salt has increased the extracellular fluid of the body by 10 to 20 per cent, edema appears regardless of venous pressure. This will first be evident in the sites where tissue pressure is low, pulsation is small and venous pressure relatively high. In the splanchnic area, which drains through the portal vein, venous pressure is relatively high in all mammals. In man, due to the erect posture, venous pressure is relatively high in the legs during much of each day and it is high in the dorsal part of the lungs when man is supine in bed. In most mammals retention of fluid is first evidenced by ascites; in man it is first apparent in the legs by day and in the lungs at night. In many women premenstrual edema occurs as a result of the salt-and-water-retaining action of ovarian steroids. This usually takes the form of edema of legs and ankles; it occurs with normal levels of protein, venous pressure and pulse pressure. Similar edema can be evoked with desoxycorticosterone, or with daily doses of sodium chloride over 25 to 30 Gm. If cardiac failure is latent, any of these causes for ankle edema may produce pulmonary edema beginning usually with acute nocturnal seizures.

*Pulmonary Edema.*—While the spongy pulmonary tissue would appear to be a preferred site of edema formation, it must be remembered that the mean pulmonary arterial pressure is actually less than the colloidal osmotic pressure of plasma, so that transudation will occur slowly under normal conditions. Even after pulmonary hypertension has developed, the high pulse pressure, the rapid lymph flow and the evaporation from aerated alveolar surfaces all serve to cut down pulmonary edema. When venous pressure rises gradually, over months or years, as in the lungs in disease of the mitral valve, the walls of the venules are structurally altered, so that transudation is matched by lymph flow under the existing venous pressure levels.

Pulmonary edema occurs late in hypoproteinemia or when pulmonary venous pressure rises steadily to abnormally high levels, but it may be the first sign of cardiac insufficiency. In the past, this has been blamed on "left-sided failure," because it was usually seen in aortic valve disease and in hypertension; no one seemed disturbed by its late occurrence in that form of disease of the left side of the heart, mitral stenosis, in which pulmonary venous pressure was highest and the capacity of the left side of the heart to receive and forward blood was least adequate to respond to bodily needs or right ventricular output. In mitral stenosis pulmonary arterial pressure rises, secondary to the rise in venous pressure in the lungs, and the right ventricle often is greatly hypertrophied. From appearances, this right ventricle should be able to force large amounts of blood into the lungs and thus overwhelm the left side. But pulmonary edema occurs late, when generalized edema and ascites are well defined. In patients who do have pulmonary edema, the left ventricle is hypertrophied, while the right may be normal. Any acute rise in pulmonary venous pressure and resistance to pulmonary flow would seem far more likely to reduce right ventricular output in these persons than in the patients with mitral stenosis. And as the patients who get acute pulmonary edema often do so at night, when bodily demand for blood flow is minimal, and are able to carry out vigorous effort by day, it seems unlikely that high right ventricular output alone causes pulmonary edema in these cases. The paradox of acute pulmonary edema is best understood by comparing what happens in a typical day in mitral stenosis and in a case of aortic disease with acute nocturnal dyspnea due to pulmonary edema.

## EFFECT OF SODIUM RETENTION

*Mitral Stenosis.*—A patient with mitral stenosis, slight ankle edema and an enlarged liver has learned that she sleeps better propped up on several pillows. In the sitting position, even in normal persons, vital capacity is higher than when recumbent. As the center of mass of the left ventricle averages 7 to 10 cm. lower, in relation to the center of mass of the lungs, in the erect position than when one is supine, the average pulmonary venous pressure must rise 5 to 8 mm. of mercury in order to maintain the same blood flow in the supine posture as when erect.[14] Cardiac output rises when one lies down, partly because the venous blood trapped in the legs and abdomen by gravitational pressure in the veins flows back into the main venous reservoir, partly because a slight fall in peripheral resistance and in diastolic pressure occurs when the cerebral region is lowered to the plane of the heart. On going to bed, therefore, everyone experiences a rise in pulmonary venous pressure and a lower venous pressure in the legs. In mitral disease both effects are reduced, because the patient usually sleeps propped up in bed. Because pulse pressure in persons with mitral disease is usually low, and the legs are still below the cardiac level when the patient sleeps, edema fluid is mobilized slowly and sudden shifts of blood and edema fluid seldom occur at night. If such a patient has much salt at dinner, she usually notices that her legs are more edematous next morning, and her dyspnea on dressing may be increased.

*Aortic Insufficiency.*—On the other hand, a well-compensated middle-aged man with aortic insufficiency usually has high pulse pressures in his legs and no decrease in cardiac output under basal conditions. On exercise, his pulse pressure increases, but if he is on his feet and working all day, his output may not rise enough to prevent decrease in renal blood flow, with salt and water retention. Usually this is excreted as fast as it is mobilized from his lower extremities after he goes to bed. His cardiac output is normal for basal conditions, and in bed it is not as great as when he was exercising and had muscular vasodilatation by day. One day his exertions are greater, his salt intake higher and his fluid retention more than usual. Although he has not noticed edema of his ankles, when he lies down a liter or more of saline solution rapidly is mobilized into his blood stream, raising effective blood volume and cardiac output even higher than it usually is when he is in the recumbent position. Since his muscles are at rest and muscular vasodilatation absent, systemic resistance is relatively high. In aortic insufficiency the left ventricle empties its huge stroke volume but diastolic reflux is increased if the peripheral vascular tone is high.

---

[14] Dock, W.: Anatomical and Hydrostatic Basis of Orthopnea and of Right Hydrothorax in Cardiac Failure, Am. Heart J. **10:** 1047-1055, 1935.

As a result of increased stroke volume without vasodilatation, left ventricular diastolic pressure and pulmonary venous pressure soon rise above the daytime level. Edema begins to form in the lungs, where ventilation is minimal and evaporation much less than when the patient was active during the day. Most of the lung is dependent to the left ventricle, and edema forms readily at the most dependent parts. Aeration ceases in these, and arterial cyanosis develops as blood pours through these airless lobules. Arterial anoxia causes reflex pulmonary vasoconstriction and rise in heart rate; these in turn reduce pulmonary pulse pressure and lymph flow. Pulmonary edema rapidly increases. The man awakes, gasping and frightened. Breathing now causes audible rattles, which frighten him more, and this in turn causes pallor and further systemic vasoconstriction, accelerated heart action with further loss of myocardial efficiency, further rise in ventricular diastolic and pulmonary venous pressures. Now, even if he sits up, the pulmonary edema may increase, but it will gradually disappear if he walks about or if the vicious circle is broken by the relaxation afforded by morphine, the improved heart action effected by strophanthin, or the fall in venous return which follows venesection or pressure breathing with oxygen.

If this man had ingested only 200 mg. of sodium the previous day he could not have retained enough saline fluid in his tissues to initiate the episode; had he been given a mercurial diuretic at 5 p. m. he would have been disturbed by nocturia but not alarmed by dyspnea. A comparison of cases of mitral and aortic heart disease brings out the relative unimportance of venous hypertension in relation to the signs and symptoms of cardiac insufficiency. Because episodes of nocturnal dyspnea occur with little other evidence of heart failure, some physicians have though the attacks must be of nervous origin. Yet the dramatic nature and occasionally fatal outcome of such bouts have led others to regard them as evidence of severe heart failure. This seldom is the case; not infrequently a man with aortic insufficiency will be able to resume hard work the morning after such a seizure.

*Advantages of Sodium Restriction.*—What is proved by these cases is that nothing is more harmful to the person with cardiac disease than rapid increase of blood volume by infusion of saline. The effects are especially striking when patients are suffering from febrile illness, or have been undernourished, or have just undergone operative intervention. Then liberal administration of isotonic sodium chloride solution by vein can quickly precipitate acute pulmonary edema even though myocardial failure is minimal. The rapid mobilization of edema fluid from the legs, when an ambulatory patient lies down flat, imposes a similar burden on the heart and lungs. Because they do not evoke vasodilatation or increased pulmonary ventilation, meals rich in salt and infusion of saline solution actually are worse for the heart and cause pulmonary edema in the recumbent patient much more readily than does moderate exercise in the erect posture.

About 3 Gm. of sodium must be retained to form every liter of edema fluid. When the vena cava is ligated, venous pressure in the legs is higher than in most persons with cardiac disease, but there is no sodium retention by the kidney, lymph flows freely and edema of the legs is minimal. When cardiac output falls below optimal, even though systemic venous pressure is normal, edema, ascites and hydrothorax develop if the patient is active by day and has a liberal salt intake. Among the great apes, living on seeds, nuts and fruit, sodium intake rarely is over 250 mg. on a 3,000 calorie intake; among primitive people in the tropical rain forests it is rarely more than 500 mg. per day, and often is much less. On many American diets, the sodium intake exceeds 5 Gm. per day. A truck-driver, eating four meals a day in restaurants, retained over 9 Gm. of sodium a day for three days at the onset of acute nephritis. The mechanism for sodium retention, evoked whenever actual cardiac output falls below optimal levels, is invaluable to tide men and animals over hemorrhage or shock but may lead to rapid development of anasarca when persons on modern highly unphysiologic levels of salt ingestion have even moderate degrees of heart failure for a few days.

Rate of edema formation in the person with cardiac disease is determined more by salt ingestion than by reduced cardiac output and renal blood flow, and is therefore a poor sign of the severity of failure. Its localization is not always a dependable clue to the side of the heart on which venous pressure is most elevated. Women with hypertensive heart disease often have severe ankle edema with normal systemic venous pressures. A patient with aortic, mitral and tricuspid insufficiency may have a pulsating liver but no orthopnea or ankle edema in spite of a low cardiac output and extremely high systemic and pulmonic venous pressure. Pulsation and lymph flow in such a patient's tissues are unusually good, and the blood volume is high in relation to extracellular fluid.

### PULMONARY EDEMA AFTER MYOCARDIAL INFARCTION

The development of acute pulmonary edema within a few hours after the onset of myocardial infarction with evidence of peripheral vascular collapse is not uncommon. Here blood volume and extracellular fluid volume may be normal at the onset, and it therefore has been customary to ascribe the pulmonary edema to high venous pressure back of the injured left ventricle. In these cases the pulmonic second sound, as well as the other heart sounds, is usually faint. Pulmonary arterial hypertension, which invariably accompanies significant rise in pulmonary venous pressure, is absent or minimal. Pulmonary venous hypertension probably is a minor factor in this type of edema, which has been observed in other types of shock, including the shock induced in dogs by removing 25 per cent of their blood volume.[15] Pulmonary edema in these states of profound shock is apparently due to injury to the pulmonary capillaries by the products of tissue anoxia; it is aggravated by infusion of saline solution but not by transfusion. Once pulmonary edema became recognized as a sequel of peripheral shock, the mystery of pulmonary edema in acute coronary attacks, with faint pulmonic second sounds, appeared to be solved, and the rationale of transfusion in this type of shock was established.

Pulmonary edema and hydrothorax rather than high venous pressure are the important pulmonary factors in causing dyspnea in heart failure. Since cardiac edema results from the changes evoked by a decline in adequacy of cardiac output, even cardiac dyspnea is due, fundamentally, to the decrease in effectiveness of systolic discharge and the ingestion of too much salt. The aim of therapy is, therefore, to reduce the bodily demand for a large volume of blood flow, to increase the effectiveness of systole and to combat the rise in blood volume and extracellular fluid volume by withdrawing sodium or by venesection.

[15] Eaton, R. M.: Pulmonary Edema: Experimental Observations on Dogs Following Acute Peripheral Blood Loss, J. Thoracic Surg. **16**: 668-694, 1947.

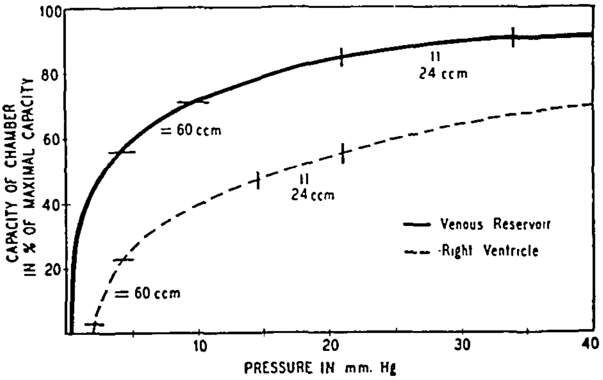
*Adaptation of Body to Lessened Cardiac Efficiency.*—While it is not possible to study the rate at which the body adapts in various ways to a falling level of cardiac efficiency, it has been most instructive to observe adaptation to rising myocardial efficiency under therapy. In a group of patients with low cardiac output, observed by DiPalma,[16] the blood volume prior to therapy was over 100 cu. cm. per kilogram of body weight, as compared to less than 80 cu. cm. in normal persons and 85 cu. cm. in a group with failure due to high cardiac output. Circulation time averaged 26 seconds in the high output group and 39 seconds in those with low output. The latter group, during two weeks of definite clinical improvement, had a fall of 65 per cent in circulation time and 28 per cent in blood volume. In the high output group, with striking clinical improvement, the fall in blood volume was only 5 per cent and that in circulation time was only 35 per cent. Red cell mass remained constant in those with high output but fell 25 per cent during recompensation of the low output group. In the latter group, total plasma protein values fell faster than blood volume, so that on the third day of therapy the serum protein level had fallen from 6.5 to 5.8 Gm. per hundred cubic centimeters, the blood volume from 7,400 to 6,200 cu. cm.

It is thus proved that when venous pressure rises, a high blood volume can be maintained only by increasing the total mass of blood protein and red cells, and when venous pressure falls, protein and red cells must be destroyed in order for a decline in blood volume to occur. In failure with high output, peripheral vasodilatation allows blood to enter venules under relatively high pressure, and to return rapidly to the heart even if the venous channels are relatively narrow, due to high venomotor tone. In such cases blood volume increases but little in heart failure, and if anemia is severe, the volume remains less than normal. With low output failure, the body is able to get along with a reduced total blood flow, and there is a vasoconstriction which reduces the pressure under which blood enters the venules. Wide venous channels and sluggish return flow call for a great increase in blood volume in these cases, and circulation time is slow. In both types of cases the most suitable adjustments are effected by the body.

## THE NATURE OF COMPENSATION

The mechanisms called into action by a decrease in the ratio of actual to optimal cardiac output are effective in increasing venous return. When heart failure and rise in diastolic pressure in the ventricles are minimal, this suffices to raise cardiac output by increasing diastolic filling. At longer fiber length, as Starling demonstrated, the ventricle releases more energy and does more work at the ensuing systole. In advanced failure further dilatation may actually decrease stroke volume, and in such instances cardiac output falls on exercise or on lying down and rises following venesection. These patients are also the ones in whom great improvement, with decrease in heart size, occurs if they learn to live on diets low in sodium and protein. If metabolism is lowered and compensatory rise in blood volume is prevented, such patients are greatly benefited.

As failure progresses, output is not restored to optimal levels by rise in venomotor tone and in blood volume. In veins and ventricles, as in a rubber balloon, stretch decreases as pressure rises. At high levels of pressure, in the ventricles and the venous reservoirs, relatively small changes in volume occur with large changes in pressure. Where normally 60 cu. cm. can be transferred from auricles and veins to ventricles in early diastole with a rise in ventricular and fall in venous pressure that totals 10 mm. of mercury or less, at high pressures in a heart of the same size, 25 cu. cm. transferred from venous reservoir to ventricle will equalize pressure in the two chambers, with pressure changes totaling 20 mm. of mercury or more. (See the accompanying chart.) Only by decided hypertrophy of the ventricles and the venous reservoirs can a normal stroke volume be restored to an inefficient overburdened ventricle. This type of hypertrophy does occur and explains why, in chronic heart disease, capacity for exercise may be restored to a considerable degree even though venous pressure is decidedly elevated and the shadow of the heart is abnormally large. The capacity for coronary flow increases with the ventricular weight, as long as atherosclerosis spares the large arteries.[17] Such a heart shows true compensation; the extrinsic mechanism has furnished an adequate blood volume and venous pressure, the vascular bed and heart have provided capacity to permit adequate stroke volumes at high ventricular diastolic pressures; high diastolic pressures in the ventricle evoke adequate systolic emptying. Cardiac output now more nearly approaches optimal under basal conditions or even under stress. Renal and splanchnic blood flow approach normal levels, salt and water excretion balance ingestion, and the patient's circulation is reestablished in spite of a weakened and overburdened heart. Further stress and weakening produce new episodes of failure, and eventually recompensation fails.



Volume-pressure relationships of the ventricles and venous reservoirs: The horizontal lines show the pressure changes recorded in the normal subject, the vertical lines those recorded in severe heart failure, during the equalization of auricular and ventricular pressures occurring in early diastole. The stroke volume in the normal is taken as 75 cu. cm. with 80 per cent of filling occurring in early diastole. The volume noted for the case of failure is that which would be possible without hypertrophy: approach to normal stroke volume is made by hypertrophy of the ventricle and the venous reservoir.

---

[16] DiPalma, J. R., and Kendall, P. E.: The Relationship Between Blood Volume and Blood Specific Gravity in the Recovery from Cardiac Decompensation, J. Lab. & Clin. Med. **29**: 390-397, 1944.

[17] Dock, W.: Capacity of Coronary Bed in Cardiac Hypertrophy, J. Exper. Med. **74**: 177-186, 1941.

But intervals of years, or even decades, of effective living may pass between one episode of failure and the next. During all this time, heart volume, circulation time and venous pressure are abnormal and vital capacity is low. Yet dyspnea at rest is absent, dyspnea on effort is moderate, and edema does not develop on diets reasonably low in salt. Recovery from cardiac insufficiency occurs when heart volume, vital capacity and venous pressures return to normal; compensation occurs when the patient learns to live on satisfactory terms with a dilated and hypertrophied heart.

### SUMMARY

The adaptations of the body to reduced venous return to the ventricles (shock, pericardial embarrassment) or to diminished force of ventricular beat (myocardial failure) are numerous and effective. In some cases, decreased utilization of blood by the body is a striking feature, output remaining low and the tissues adapting themselves to low oxygen and high carbon dioxide tensions. In others, where peripheral vasodilatation is essential to maintain life of the tissues, blood flow may be twice normal under basal conditions in heart failure. Then again, high arterial pressure may be maintained in spite of cardiac insufficiency. In all cases venous tone rises, the renal and splanchnic blood flow falls, the blood volume and extracellular fluid volume increase. Whether rise in venous tone or in blood volume is most pronounced depends on whether the body can be satisfied by an output less than normal and a sluggish return flow through wide venous channels (low output failure) or whether arteriolar vasodilatation raises venous pressure and permits rapid return flow through narrow channels (high output failure).

To adapt itself to high arterial pressures the ventricle hypertrophies in thickness, with little change in capacity; the reverse is true in hypertrophy to maintain high outputs at normal or low diastolic pressures.[18] To adapt to high ventricular and venous pressures, when muscular efficiency is low, the ventricles and the auricles and great veins grow to be exceedingly capacious; they may finally maintain a normal stroke volume with the heart and venous reservoir three to ten times as capacious as normal.

These adaptations would be rather effective if the patient remained on a diet with a normal mammalian salt intake (less than 1 Gm. a day) and as long as he did not lie on his back. If he does the latter, pulmonary edema may develop, which can scarcely occur when the heart and lungs maintain the relations normal in mammals, the heart lower than the lungs in the gravitational field.[18] Man has not yet succeeded in effecting circulatory adaptation in the postures and on the diet which he has taken up recently in his evolutionary history. Chronic heart failure, as seen clinically, represents a combination of superb physiologic response to stress, with the breakdown of this mechanism due to man's wilful insistence on a perverted diet rich in salt and his preference for the supine rather than the prone posture when at rest. It probably will prove more effective, in the long run, to develop agents which permit man to eat his salt and not absorb or retain it, than to try to cure him of his acquired taste. And it is much easier to raise the head of his bed 18 inches (46 cm.) than to teach him to sleep on his face or propped up on pillows.

## MEDICINE AND THE STATE

LORD HORDER, G.C.V.O., M.D., F.R.C.P.
London, England

When you paid me the honor of asking me to present this lecture, you will remember that I did not delay in my acceptance of your invitation. Aside from the distinction enjoyed by your society, the realization that I was following men like Thayer, William Mayo, Charles Martin, Walter Cannon, George Minot and Ludvig Hektoen, who, in addition to their eminence in medicine had been, and are, much esteemed friends, gave me a thrill of pleasure. The pleasure, however, was tinged with fear—that I should prove a very unworthy follower of colleagues whose names will pass into history as having contributed to the greatness of medicine.

To some who listen to me and wonder that I choose so topical a subject for my address as the relations between the doctor and the state, I would excuse myself by saying that I believe the present situation in respect of these two important elements in society today to be of vital importance to the progress not only of medicine but of civilization itself. There has been *no single* factor in the evolution of the human race, whether regarded physically or morally, so great as medicine. To substantiate this claim would take me much too far afield.

I am concerning myself this evening with the interaction of medicine and the state *in their joint effort* to help forward human progress through a scheme of *medical care for the people.*

### REQUIREMENTS FOR IDEAL MEDICAL CARE

In the first place, therefore, I suggest that we define our needs in regard to an ideal scheme of medical care. This is not really very difficult.

1. We must help the fit to remain fit, by "keeping the ring" for them and by preserving the amenities. There was formerly an "occupational" fitness but this has seriously diminished, largely as the result of urbanization of great numbers of our citizens. We must also help the near-to-fit to be quite fit. This does not require artificial means, because health is a natural thing—Nature tends that way if she is given a chance.

2. We must raise the general standard of fitness (i. e., health) by correcting certain tendencies toward lowering it which are inherent in modern life. The life led by many clerks, miners and school children impedes natural functions. More important still, we must provide enough of the proper food for those millions of our fellows who do not at present get it.

3. We must do our utmost to control disease due to preventable agents. This means research and an army of well trained medical officers of health to implement the knowledge that we have and are yearly increasing.

4. We must cure or alleviate disease when it occurs. This means an army of well qualified doctors for attendance on the family in its homes, and well equipped hospitals for institutional treatment.

These are our needs, and they should be considered in that order—more and more in that order as civilization progresses and as the grosser infections come under control.

---

Chairman of the Fellowship for Freedom in Medicine, London.

William W. Root Lecture, delivered at the Annual Dinner of the Alpha Omega Alpha Society, Atlantic City, N. J., June 9, 1949.

### PRINCIPAL FACTORS IN MEDICAL CARE

In trying to satisfy these requirements we are all concerned, not merely the doctor, the medical officer of health and the administration, but the people themselves. You cannot make people healthy any more than you can make them good.

Of the citizen I do not speak today, important though his contribution is. The second party in the scheme is the doctor, the "health man" who makes contact with the citizen and "gets the thing across." He is the most important part of the medical care system, because it falls to him to diagnose the citizen's degree of health or, alternatively, the nature and degree of the citizen's deviation from health. This function of the doctor cannot be usurped by any one else. The doctor is right and is acting in the public interest in zealously guarding this privilege—great obligations are laid on him. The fact that he enjoys public confidence to the extent that he does is proof that in the main he carries out these obligations.

The third party to the contract is the state. The function of the state in regard to medical care is to see that the whole gamut of knowledge and skill, which is resident in the physician, gets as unobstructed a channel as possible between it and the citizens. The state should help in the construction of the machine of medical care but should not itself run the machine. This is the job of the expert, and the expert is the doctor.

### PRESENT THOUGHT ON NATIONALIZED MEDICINE

With these preliminary and basic considerations let me turn to what I have called the present situation with regard to medicine and the state.

President Truman's now historical message to Congress on April 22 last opened with the following pronouncement:

> In a special message to the Congress on November 19, 1945, and in a number of messages since that date, I have recommended the enactment of comprehensive legislation to improve the health of the people.
>
> The issues involved in these recommendations have been debated all over the country. . . . There has been increasing recognition of the need for positive, planned action to bring adequate health services within the reach of all our people. . . .
>
> Legislation has already been enacted which is helping substantially to provide better health services and medical care.
>
> However, the action thus far taken falls far short of our goal of adequate medical care for all our citizens. If we are to deal with the problem realistically and in its true dimensions, action is required on a broader scale. . . .
>
> Now that we have the medical knowledge that can bring good health within our reach to a degree heretofore undreamed of, we must improve the means for putting that knowledge to practical use. Good health is the foundation of a nation's strength. It is also the foundation upon which a better standard of living can be built for individuals. To see that our people actually enjoy the good health that medical science knows how to provide is one of the great challenges to our democracy.

The President proceeded to outline in very broad terms the desiderata in respect to an extension of medical care for the whole nation and considered that this can be accomplished only by a method of compulsory health insurance.

Neither of the two terms with which we in Great Britain have become so familiar—socialized medicine and nationalized medicine—occurred in the President's message. This omission may, of course, have been deliberate. In a way, the omission of the term socialized medicine may be a good thing, because (as I have so often pointed out) it is an entirely ambiguous expression. It may merely mean making medical care available to every citizen, a purpose to which all of us with a humanist outlook must surely subscribe; or it may mean nationalizing medical practice—that is, the state taking control of the medical profession in all its branches and all the mediums through which it operates.

On July 5 last, medicine was actually nationalized in Great Britain as the result of the passing of an Act of Parliament so framed that the minister of health could, by regulations under the Act, direct the whole medical care of the country, whether operating through institutions such as hospitals or through physicians engaged in private practice. His powers under the Act are almost unlimited. I consider it vital that this distinction between socialized medicine and nationalization of medicine be made clear to the public. My own country was misled into thinking that what was intended was the socialization of medicine in the first sense I have attributed to the term, whereas what the government had in view was the nationalization of medicine in the same sense as it had nationalized the mines and the railways and now proposes to nationalize steel.

To return to the President's message, men of good will hailed this as indicating an earnest endeavor to take social betterment, through medical care, a long step forward; the cynic saw in it little else than one more example of political exhibitionism.

It does not really matter whether the message was an expression of the Messiah complex or of political expediency; what matters is that it has caught the public imagination and that the citizen has tuned in to the idea and is quite likely to ask for some practical fulfilment of the implied promise. And not only has it appealed to the man in the street—who, after all, when benefits are offered and no immediate payment of a proportionate kind is asked in return, is very prone to join that curiously mixed group which the scriptures tell us are "never satisfied"—but to more responsible folk. When I was in Washington recently, I found my colleagues of the Food and Agriculture Organization of the United Nations were also intrigued, as it were, by a presidential slogan; they were talking in terms of point 4 of the Inaugural Message and seemed to have forgotten that at Hot Springs and at Quebec the formula which guided their efforts was even wider in its scope and was several years older. This formula committed "the Nations accepting the Constitution of the United Nations to a determination to promote the common welfare—for the purposes of raising levels of nutrition and standards of living," and so forth.

There was nothing really new in all this. It was rather like opening a scientific meeting by reading the Sermon on the Mount—and why not, since science exists for man and not man for science? What is new is the emergence of the individual, an event which is the real crux of what has been called the changing order in society, and which we discussed so fully at the centennial of the New York Academy of Medicine in 1947. This emergence has synchronized with a number of profound alterations in the way of living and in social attitude. Among these are industrial expansion, poverty, the rise of big business and big government, the arrival of social service and the development of voluntary health insurance plans.

### EMERGENCE OF THE INDIVIDUAL

There are two even more basic elements in this concentration on the individual which is the fundamental feature in the changing order. The first is recognition of the fact that the citizen himself and not his goods and chattels, or the want of them, constitutes the real wealth or poverty of a nation. Thinking men have told us this again and again. (You remember the old cliché, "The health of its citizens is a nation's greatest asset.") But we did not listen until dire national peril was upon us. During the recent war we passed our men and women through a finer comb than we had ever done before, and now, in the postwar era, manpower is the commodity we find in shortest supply.

The second basic element leading to the emergence of the individual is his own spiritual evolution. That the evolution of personality proceeds along lines which tend to help humanity forward is generally accepted. In the course of this evolution the individual very reasonably says to medicine, "What can you do for me?"

Now, although it is true that, being based on science, medicine to be really progressive should command a degree of autonomy—of freedom—there is agreement that its full powers should be applied to the attainment of the health and happiness of the individual. In so far as the state acts wisely in the interests of the citizens, this desideratum has always been recognized. At first it was recognized only dimly, but later more clearly, so that there has today opened up for the statesmen, the sociologist and the physician a large field for their inquiry and their action, and this field is common ground. The man of medicine must not spend all his time in this field; he must go apart, whether in the laboratory or at the bedside, or, like Harvey, walk under the trees rapt in thought so that by observation, by experiment and by contemplation he may keep medicine dynamic. For it is through medicine that the doctor makes his contribution, a contribution which no one else can make. On the other hand, to stand aloof from the work going on in this same field is to do a disservice not only to society but to medicine itself; but to become entirely absorbed in it is to do a disservice no less serious. Sigerist said:

"The history of the medical ideal is the history of human society. Seeing that the position of the sick in society differs with every cultural epoch, the demands upon the doctor and his position in the social structure change constantly; but though they differ in detail they remain the same in their fundamental claims. The good physician was at all times the physician who felt himself bound by the medical ideal of his time. Men like Hippocrates, Sydenham, Laennac, Billroth and Osler were therefore great physicians and will always occupy a special position in the history of medicine. A clear understanding of the prevailing medical ideal is of great importance."

Can we achieve this end, about which we are all agreed? And, if so, how? Let us suppose that we in Great Britain had been given the chance of helping the state by making constructive suggestions—what would these have been? In the first place there is surely consensus concerning certain basic desiderata: 1. Medical care should provide everything that science can offer toward the preservation of health and the cure of disease; the whole corpus of knowledge, as it is termed, must be implemented in the citizen's interest. 2. Then surely it is agreed that these benefits should be available to the entire population. 3. Seeing that the general public has a vital interest in our plans, it should be adequately represented in their formation. 4. But inasmuch as it is the doctor who must render the medical care, he should play a dominant part in the preparation of the scheme he will be called on to carry out.

If, as I say, we had been consulted as to how this ideal could be achieved we should have emphasized our belief that gradual extension and improvement of medical care is preferable to revolutionary changes and that, while recognizing the responsibility of the government for the citizen's health, we should have warned the state that sweeping legislative action would defeat its own purpose by impairing the spirit and quality of a service which is essentially individual and personal.

### CRITERIA FOR ACHIEVEMENT OF THE MEDICAL IDEAL

As to the conditions necessary to bring about the desiderata I have enumerated, there are certain paramount criteria. The gist of these is that the quality or standard of medical care must be preserved; provision of public health services is, of course, essential; then there must be effective use of hospitals with adequate facilities; trained professional and nonprofessional personnel is a *sine qua non*; organization and coordination of physicians through the extension of medical groups and health centers must be encouraged; voluntary prepayment plans should be supported; extensive education for both physicians and the public is required, and, finally, government help, preferably by grants in aid, would be necessary. Indeed, a method of grants in aid would seem to offer the brightest promise, as far as help by a central authority is concerned.

We must realize that the practical expressions of unplanned energies are often cumbersome and wasteful. This is the price we pay for highly individualized societies. We began doing things many years ago; we did some of them so well that it has never been considered helpful to scrap them. There are parts of the machinery of our health services which work perfectly; some units stand out as pieces of perfect organization and efficiency—the large voluntary teaching hospital; many special hospitals; the well-managed cottage hospitals, as we term them in Britain; some of our public health services, and our Medical Research Council. A wise state, on examination of these units, will not scrap them at sight but, realizing that it cannot hope to do the thing better (or as well), will stand by them, will help them and will integrate them in a general scheme of medical care.

One other thing; to make medicine a complete science in the service of man, we must see that it infiltrates the important and now more clearly perceived sphere which lies between that in which the diseases of the individual patient are treated by the individual physician and the sphere in which the preservation of the public health is achieved by the medical officer of health. This largely untilled field includes all the environmental factors which influence health and happiness: conditions of work, home life, the sense of security or insecurity. In short, as Professor Ryle has stated: "Our next advance (in medicine) will be . . . concerned with causes, but with the ultimate, rather than the intimate, causes of disease." Professor Ryle's term "social pathology" is an apt designation for this work. A study of the environmental factors in the etiology of disease was overdue; it is high time that they were studied and the results statistically analyzed.

That, I think, is how we should have put the case for medicine in its relation to society. But we should fail in an important part of our duty if we did not, at the same time, warn the state that if it did not attend to the more basic needs of the citizens our direct contribution from medicine would avail little. By basic needs I mean: a sufficient amount of the proper food, suitable shelter and clothing, a satisfactory job of work, access to fresh air and sun, reasonable leisure and the amenities of life. The doctor must stake out the citizen's claim in every one of these needs. We physicians must lead in all this; we must guide the politicians, since they cannot act without expert help; we must keep the citizen's end up, since he learns to rely on us for support.

But suppose the politician won't be guided? Suppose it is as Swift wrote in a letter of Pope: "Although I have known many great Ministers ready enough to hear opinions, yet I have hardly ever seen one that would descend to take Advice; and this pedantry ariseth from a maxim which they themselves do not believe at the time they practice it, that there is something profound in politics, which men of plain honest sense cannot arrive to." In that case the physician has no alternative but to appeal to public opinion, continuing to serve his patient in the manner which he believes to be in the patient's best interest.

### THE NEED FOR UNITY OF ACTION

That, I say, is how we should have stated our case. And, as far as we had a chance of so doing, we in Britain did. It was a pity that we had no machinery by which we could express ourselves as a corporate whole. We had no actual guild. Lacking unity and scattered in different camps, we were taken off our feet. Precipitate action was the order of the day. We were bustled into premature action against our better judgment. The rank and file of the profession were maneuvered into acquiescence by economic pressure and not from conviction. Only unity could have saved us, and unity was what, at the critical moment, we lacked. We forgot that we were experts and that only as experts should we agree to cooperate. We moved from an attitude of dignity and calm detachment from political clamor to one of subservience to a doctrinaire socialist adventure. We ceased to be masterpieces and became pawns in the game. And so we have become what we vowed at all costs we never would become—mere servants of the medical bureau. The whole philosophy of the physician-patient relation has changed. We are no longer in control. Instead of saying "What is troubling you; tell me, so that I may help you," we say "What is it that you want?"

Those who have nationalized medicine in Great Britain call us, who have pleaded for evolution rather than revolution, reactionaries. But it is they who are the reactionaries. They have put back the progress of medicine, both in its art and its science, a hundred years. Medicine had found that the close relation of doctor and patient was the sine qua non in medical care. For the time being this has been to a large degree sacrificed.

You in America can, if you will, escape this peril. You have time. I am old enough not to be charged with egregiousness if I offer my colleagues here a warning and express a hope. Do not risk a head-on collision with the state; if you do you will lose. Accept the challenge that is implied by the President's message. "Make medicine available for every citizen," he says. "Certainly," you should say, "that is what medicine is for. But what medicine? Our medicine, the medicine that results from tradition, long training, knowledge of our fellow man and the creaming off from science of the best that it offers to the physician? Or a stereotyped medicine of the state, which is but a bastard sort of medicine?" Surely, there can be only one answer. It is easy to level down; this can be done almost by a stroke of the pen. It is difficult to level up; this takes time and labor and much thought. So, I say, do not move away from general principles; they are the only things which ultimately triumph. And what are these general principles? Expert knowledge, detachment from politics, public confidence and courage; these are the essentials that enable medicine to make its contribution to the common health and the common happiness. You have in this country fought a good fight against the quack doctor in private life. You have a harder fight before you—the fight against the quack in public affairs. Put the case for medicine before the Public,—put it clearly, modestly and briefly. This is their case as well as ours, it is even more their case than ours. I believe that, with vision, you will succeed. If you fail, if the public will not be saved, well, in the vernacular, "that is just too bad." It will be a depressing thought for me, with so many good friends among you, that, while you are a country of infinite capacity and infinite ingenuity, you are yet a country of infinite credulity!

---

# RATE OF BLOOD FLOW THROUGH STANDARD GAGE NEEDLES UNDER PRESSURE

JAMES D. BREW, M.D.
and
LESLIE V. DILL, M.D.
Washington, D.C.

The recent war coupled the great need for the rapid transfusion of blood with the need for readily available supplies of blood and plasma. The use of large needles and methods of pumping these fluids intravenously under positive pressure resulted in the transfusion of previously unheard of quantities at almost unbelievable rates of flow. Most civilian hospitals are well aware of these methods, and several articles have been published with standard technics. Reports of the use of large amounts of blood are now a daily occurrence.

Except in emergency rooms where treatment for traumatic accidents is frequent, the main need for the rapid transfusion of large quantities of blood exists almost solely on the delivery floor and in the operating room. It is still difficult, even in many well equipped institutions, to obtain the apparatus for supplying blood under pressure and needles of sufficient size for the rapid transfusion of blood.

Jean Poiseuille, about the year 1800, expressed the flow of incompressible liquids through tubes of small bore in the absence of turbulence as:

$$q = \frac{pr^4}{-8nl}$$

where q is flow in cubic centimeters per second, p is pressure in dynes per square centimeter, r is the radius of the tube, n is the viscosity and l is the length in centimeters.

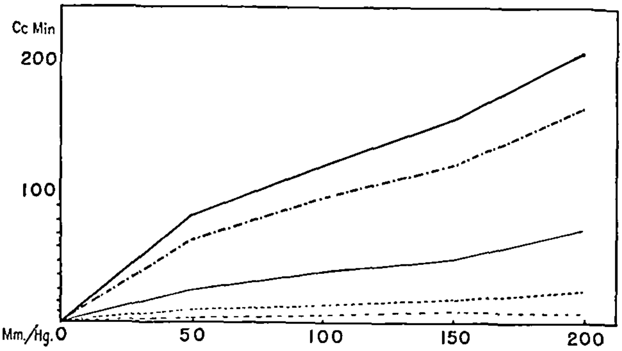
---

From the Departments of Obstetrics and Gynecology, Georgetown University Hospital and the Yater Clinic (Dr. Dill).

Reviewing this equation roughly, one may say that with a given transfusion system, and using material of the same viscosity:

$$q \text{ varies as } pr^4$$

This is of significance in that although the flow is shown to increase directly with the pressure, it increases directly with the fourth power of the radius of the end of the tube.



The rate of flow in cubic centimeters of blood per minute (vertical column of figures) through standard gage needles under the stated pressure. (The horizontal row of figures shows the pressure in millimeters of mercury.)

This paper is presented to emphasize the necessity for including in transfusion sets, as standard equipment, the materials for the rapid transfusion of blood.

## METHODS AND MATERIALS

The materials used were standard equipment modified for pressure transfusion administration. These consisted of a Baxter 19-R Y-type recipient set, blood flasks, B-D needles numbers 22 (0.016 inch, or 0.041 cm.), 20 (0.023 inch, or 0.058 cm.), 18 (0.033 inch, or 0.084 cm.), 15 (0.054 inch, or 0.137 cm.) and 13 (0.071 inch, or 0.180 cm.), an infusion stand and a mercury type sphygmomanometer with a suitable tubing arrangement for application of measured pressure to the blood flask. The fluid used in the flask was whole blood, which was in a good state of preservation.

Table 1.—*Relationship Between Blood Flow and Pressure Applied to the System*

| Needle Size | Blood Flow (Cc. per Minute) According to Pressure | | | |
|---|---|---|---|---|
| | 50 Mm. Hg. | 100 Mm. Hg. | 150 Mm. Hg. | 200 Mm. Hg. |
| 22 | 4.75 | 6.75 | 7.0 | 8.6 |
| 20 | 13.25 | 18.5 | 24.0 | 30.0 |
| 18 | 32.6 | 44.0 | 54.0 | 74.0 |
| 15 | 68.0 | 95.0 | 135.0 | 164 |
| 13 | 84 | 122.6 | 154 | 208 |

Table 2.—*Relationship of Change at Constant Pressure of Inside Diameter of Needle to Change in Flow**

| Needle Size | Increment in Bore | Increment in Flow |
|---|---|---|
| 20 | 1.4 times | 2.8 times |
| 18 | 2.0 times | 7.0 times |
| 15 | 3.4 times | 16 times |
| 13 | 4.4 times | 18 times |

* Bases of comparison are the inside diameter of the 22 needle and flow of 4.75 cc. per minute at a pressure of 50 mm. of mercury.

The apparatus was set up as if for pressure transfusion, with rubber reinforcements applied at weaker points to protect against disruption. The blood flask was placed at a level 28 inches (71 cm.) above the needle adapter. Needles of the various sizes were fitted to the needle adapter, and flow rates of fluids throughout the system were recorded with pressures of 50, 100, 150 and 200 mm. of mercury.

Two readings were obtained at all pressures for each type of needle on three separate blood samples. The average obtained from the series is presented in the charts.

## RESULTS

Table 1 and the chart show the rates of flow as recorded by the equipment described, with needles varying in size from 22 (0.016 inch [0.041 cm.]) to 13 (0.071 inch [0.180 cm.]), with pressures varying from 50 to 200 mm. of mercury.

It is noted that the flow increases directly with pressure and becomes doubled with an increase in pressure of four times in needle size from 22 to 18. With the large bore tubing, the flow at 200 mm. of mercury of pressure is approximately 2.5 times that at 50 mm. of mercury of pressure.

The most obvious observation is not the increase in flow with increase in pressure, but the vast difference in flow occurring from smaller to larger needles. Table 2 shows the increase in flow at a constant pressure with increasing diameters of needles.

The largest increment in flow occurred between the 18 needle and the 15 needle, where the diameter changed 1.4 times but the flow was increased 9 times.

## COMMENT

It may be seen from the tables and the chart that the use of a pump except on an exceedingly small bore needle (specifically, 22) increases the flow through that system linearly and roughly in proportion to the increment in pressure. Viscosity effects and eddy currents produced by irregularities of bore of the system undoubtedly account for the loss in flow over the theoretical values. The most striking difference noted was the sudden increase in flow in changing from an 18 to a 15 needle, even without pressure other than the force supplied by gravity (roughly taken as 50 mm. of mercury).

There are objections to the use of a needle of this large bore, but for the most part they are theoretical and greatly outweighed by the advantages. Objections given are: (1) difficulty in insertion in patients with small or collapsed veins, (2) unavailability of such needles in standard equipment and (3) the danger of overloading the right side of the heart with rapid inflow of fluid. In patients with small veins, when no real reason for rapid transfusion is evident, a smaller bore needle may be substituted until the need for rapid transfusion is imminent. In patients with collapsed veins due to shock, there should be no quibbling—the largest bore needle that can be insterted into the vein should be used and a cut-down made of large veins with the insertion of a cannula effected without loss of time.

The last objection, that of overloading the right side of the heart with large amounts of blood, is valid only in patients not in shock or whose circulating volume has not been depleted. *It is true that blood being pumped* into a normally circulating volume at the rate of 60 cc. per minute may cause right-sided cardiac failure, or in patients with myocardial damage this may be a valid contraindication even in the presence of mild shock. There is no reason to believe that pulmonary edema from overloading the circulation can be produced in patients with normal cardiovascular systems who have lost blood rapidly.

### CONCLUSIONS

When the need or possible need for the rapid transfusion of blood exists, a transfusion set which can constantly infuse large quantities of liquid should be utilized. The effect of rapid blood loss may be minimized by the application of pressure within physiologic limits and the use of needles of sufficient bore to allow infusion of large quantities of blood. Under the conditions of this experiment, it would seem that the utilization of pressure from 100 to 200 mm. of mercury on the transfusion system and 15 gage needles will suffice to transfuse blood at a rate sufficiently rapid to meet all but the most severe and sudden types of blood loss.

# CLONORCHIASIS IN THE UNITED STATES

## Report of Four Cases

MORTON H. EDELMAN, M.D.
and
CLIFFORD L. SPINGARN, M.D.
New York

Human infection with Clonorchis sinensis (the Chinese liver fluke or the Oriental bile duct fluke) has been encountered infrequently outside of the Far East. Reports in Western medical literature deal largely with the infection in Chinese and Japanese who have emigrated.[1] However, Binford[2] reported 4 instances of clonorchiasis in leprous Hawaiians; the disease was contracted, presumably, by the ingestion of fish imported from China. Howard[3] observed the disease in an Englishman who had never left Great Britain.

During the past eighteen months, in the course of routine examinations for intestinal parasites, we detected the ova of C. sinensis in the stools of four Caucasians living in New York City. These persons had come to the United States from Shanghai, China, where they had lived for several years. To our knowledge these are the first cases of this disease among members of the white race to be observed in this country. The discovery of these cases is another example of the global dissemination of regional diseases by the movement of populations as a result of the last war. It is likely that other persons infected with C. sinensis are already in our midst or will live in the United States in the future. This possibility has been favored by the presence of our military forces in China, Korea and Japan, the principal endemic foci of clonorchiasis. In fact, a recent report stated that this disease was observed among American military personnel in China.[4] It is the purpose of this communication to present clinical data obtained in the study of the 4 cases of infection with Clonorchis and to review briefly the principal epidemiologic and clinical features of the disease.

### GENERAL CONSIDERATIONS

*Geographic Distribution.*—Clonorchiasis is encountered chiefly in China, Japan and Korea; it occurs also on the island of Formosa and in French Indo-China.[5] The heaviest incidence is in South Central China, in Kwangtung Province, where 80 per cent of the population of Canton were found to harbor the parasite.[5] In Hong Kong 13.9 per cent of the postmortem examinations in one survey revealed infection with Clonorchis.[6] Recent studies indicate that the Shanghai district is an important focus of this disease.[7] Clonorchiasis occurs throughout Japan, with the heaviest foci of human infection in the prefectures of Okayama, Saga, Hyogo and Saitama. In 1938 a survey of intestinal parasitism in Japan revealed that 0.26 per cent of 346,353 persons found to be carriers of the eggs of parasites harbored liver flukes.[8] In Korea this disease is widespread. The incidence is greater in the southern part of the country, especially in the lowlands. In certain regions 10 to 25 per cent of the persons examined in surveys were found to be infected.[9]

*Epidemiology.*—Clonorchis sinensis is a small trematode (fluke) which resides in the biliary passages of fish-eating mammals. It was first described in man by McConnell in 1875 at the autopsy of a Chinese in Calcutta.[10] Our knowledge of the life cycle of the fluke and the manner of human infection is due largely to the studies of Faust and associates.[11] The trematode ova are passed in human or animal feces and, on contact with fresh water, liberate free swimming, ciliated miracidia which parasitize various species of small snails, Parafossarulus striatulus (China), Parafossarulus var. japonicus and Bulinus fuchsiana (Japan). Within the snail they give rise to sporocysts. Finally, free-swimming cercariae are liberated from the snail and live for twenty-four to forty-eight hours. If the cercariae reach a suitable fresh water fish, they penetrate the musculature and encyst there as metacercariae. After ingestion of the fish by man, the encysted metacercariae give rise to the adult worms. About forty species of Oriental fish belonging to the families Cyprinidae, Gobiidae, Anabantidae and Salmonidae have been reported as naturally infected.[5]

The ingested metacercariae excyst in the duodenum of man, and the larvae migrate to the common bile duct and the intrahepatic biliary channels, where they mature into adult worms in one month. The adult flukes cannot withstand the action of the intestinal juices. The ova, deposited in the biliary passages, find their way to the intestinal tract either directly or after being

stored in the gallbladder. In heavy infections ova are also deposited in the pancreas.[12] The entire life cycle from ovum to adult fluke is completed in three months.

In a study of the fish-eating habits of Chinese who harbored C. sinensis,[11] it was observed that 58 per cent ate raw fish prepared in salads, 18 per cent ate raw fish dipped in boiling water, broth or congee (rice gruel), 14 per cent ate the fish slightly fried, 6 per cent ate it dry and 4 per cent cooked the external part leaving the inside uncooked. The 4 infections reported by Binford among leprous Hawaiians [2] were acquired, presumably, by the eating of imported fish. Howard's case in England [3] probably involved infection in this manner. In a case recently reported by Crawford [4] the patient ate fish at a Chinese banquet on only one occasion.

In the Chinese province of Kwangtung, the principal focus of the disease, the raising of fresh water fish in ponds is an important industry, and night soil, which is considered necessary for the development of the fish, is fed regularly to them. This practice, coupled with the fact that thin slices of raw fish are a popular delicacy, favors the widespread dissemination of the disease.[5]

In China and Korea the spread of the disease is favored by the infection of cattle, dogs and cats. Twenty-five per cent of the dogs in Peiping, China, and 8.5 per cent of the street dogs in Mukden, Manchuria, were found to be infected. Rats may also serve as reservoir hosts. The presence of the infection in animal hosts in North China, Manchuria and Korea is an indication of the danger of infection when uncooked or insufficiently cooked fish are eaten in these areas.[5]

*Pathology*.—The majority of adult worms live in the large bile ducts with the production of distention, dilatation and eventual thickening of these passages. Hoeppli made a detailed postmortem, histologic study of the livers of 66 Chinese who were infected with C. sinensis but who succumbed to other diseases.[12] He found fibrous thickening and dilatation of the larger bile ducts and increase in the periportal connective tissue in 49 cases. A definite cirrhosis, similar to Laennec's cirrhosis except for the presence of the parasite, was noted in only 1 case. In addition, Hoeppli observed proliferation of epithelium of the bile duct, eosinophilic infiltration and fatty changes in the hepatic cells. Involvement of the pancreas occurred in 11 per cent of the cases.

Helwig and Brown,[1e] in a study of 2 cases in which necropsies were performed, described fibrous connective tissue surrounding the dilated hepatic ducts. The spaces around the ducts were infiltrated with inflammatory cells, including eosinophils, neutrophils, moderate numbers of lymphocytes and plasma cells. The adult flukes were found in the dilated hepatic ducts but not in the gallbladder, cystic or common bile ducts. Miyaka found an adult worm in the center of a gallstone.[13] Otto [14] has described a catarrhal cholangitis associated with the occlusion of the larger biliary passages by sticky masses of Clonorchis ova. The reports of Katsurada, Mebius and Yamigima [13] indicate that in long-standing cases with repeated heavy infections, cirrhosis of the liver is not rare. If the disease is progressive, ultimately a true cirrhosis results in shrinkage of the liver with alterations of the architectural pattern, splenomegaly and ascites. The observations are those of cholangitic biliary cirrhosis. The patient of Favorite and Horneff [1d] had edema and ascites for six years, followed by dyspnea and cyanosis; at necropsy the observations were indistinguishable from those of Laennec's cirrhosis, except that the bile ducts were distended with numerous trematodes. Bercovitz [15] found a fatty cirrhosis in one of his cases.

Those who are most familiar with this disease have suggested that primary carcinoma of the liver may be related in some way to the presence of C. sinensis and the pathologic changes it produces in this organ. Hoeppli [12] has stated that it is the impression of some physicians in China that primary carcinoma of the liver is more frequent in the south of China than in the north and parallels the incidence of infection with Clonorchis, which is greater in the south of China. In a case reported by Swalm, Gault and Morrison [1b] an aspiration of the liver which was performed after death in a patient with clonorchiasis revealed interlobular cirrhosis and primary carcinoma of the liver.

## REPORT OF CASES

CASE 1.—A white Russian woman aged 34 complained of low grade fever for six years. She was born in Manchuria but had lived in China for fifteen years. For ten years prior to visiting the United States she had resided in Shanghai, where she had eaten fresh water fish. In 1942, one year after the onset of a low grade fever, she was told that she had an enlarged liver. In 1943 she had an episode of intense jaundice with dark urine and clay-colored stools. In 1944, because of fever and hepatomegaly, amebiasis was suspected and she was given twenty injections of emetine hydrochloride. Since then she continued to have frequent attacks of dull pain and tenderness in the right upper quadrant of the abdomen and elevations of temperature to 100 or 101 F.

Physical examination revealed a well developed, well nourished white woman in no distress. There were a few spider telangiectases on her cheeks and nose. The lungs were clear. There was a soft apical systolic murmur. The edge of the liver was palpable in the epigastrium. The spleen could not be felt.

The hemoglobin concentration of the blood was 15.5 Gm. per hundred cubic centimeters; the white blood cell count was 5,300. The differential count revealed 44 per cent polymorphonuclear neutrophils, 40 per cent lymphocytes, 4 per cent monocytes and 12 per cent eosinophils. Urinalysis did not reveal the presence of albumin or sugar. Several examinations of the stool by direct saline smear revealed numerous ova of C. sinensis and Trichuris trichiura. A stool flotation test, with zinc sulfate (33.3 per cent solution), was negative for protozoan cysts. The cephalin flocculation test gave a 2 plus reaction. The erythrocyte sedimentation rate (Linzenmeier) was normal. Blood agglutination reactions for Brucella abortus and Brucella melitensis were negative. Oral cholecystography, performed after the administration of iodoalphionic acid (priodax®), revealed fairly good visualization of the gallbladder. There was no evidence of any filling defect in this viscus, and biliary calculi were not demonstrated.

To treat the infection with C. sinensis, the woman was given 60 mg. of methylrosaniline chloride orally, three times a day, in the form of enteric-coated tablets (enseals®). She did not tolerate this medicament well and had to forego it for two or three days at a time because of nausea and diarrhea.

[15] Bercovitz, Z.: Clinical Studies on Human Infestation with Liver Fluke (Clonorchis Sinensis), Am. J. Trop. Med. **11**: 43-46, 1931.

However, the use of the drug was associated with a prompt decrease in the number of Clonorchis ova in the stools, and several negative stools were obtained. There was also a decrease in eosinophilia from 12 per cent when the treatment was started to 3 per cent after six weeks. Symptomatically, the patient seemed somewhat better as a result of treatment. The hepatic tenderness disappeared, she had afebrile periods lasting several weeks, and she gained 5 pounds (2.3 Kg.).

On examination of the patient eight weeks after treatment was discontinued, the liver could be felt 1 fingerbreadth below the costal margin. The patient had eosinophilia (5 per cent) and her stools contained ova of C. sinensis.

CASE 2.—A woman aged 25, who had been in the United States for two months, was seen in the outpatient department of Mount Sinai Hospital. Her main complaint was epigastric pain of two years' duration. She was born in Germany, but since May 1939 she had lived in Shanghai. There she often tasted chopped fish prior to cooking it. In 1940 she had intermittent attacks of diarrhea, and she was told that she had "intestinal worms." In 1943 she contracted amebic dysentery, for which she was given emetine hydrochloride.

The recurrent epigastric pain, which had been present since 1946, appeared after meals and radiated to the back. The attacks of pain usually lasted about fifteen minutes. At times they were accompanied by periodic nausea and constipation, anorexia, weakness, insomnia and bitemporal headaches. Prior to hospitalization she had been treated with twelve injections of histidine monohydrochloride (larostidin®) without abatement of her symptoms.

Physical examination revealed a well developed and well nourished woman in no distress. There was tenderness in the epigastrium and in the lower part of the abdomen. The liver and spleen were not palpable. The blood pressure was 90 systolic and 60 diastolic.

The hemoglobin concentration of the blood was 11.6 Gm. per hundred cubic centimeters, and the red blood cell count was 3,560,000. The white blood cell count was 8,050, and the differential count revealed 53 per cent polymorphonuclear neutrophils, 33 per cent lymphocytes, 12 per cent eosinophils and 2 per cent monocytes. The urine was normal, and response to the Wassermann test was negative. The erythrocyte sedimentation rate was 11 mm. per hour (Westergren).

Blood chemical studies revealed an icterus index of 3 units, a negative van den Bergh reaction and a serum bilirubin level of 0.2 mg. per hundred cubic centimeters. Examination of the stool revealed ova of C. sinensis.

Cholecystographic study disclosed a gallbladder with a phrygian cap type of configuration, with good function and without evidence of calculus formation. Roentgenologic study after ingestion of a barium meal did not reveal evidence of abnormality in the esophagus, stomach or duodenum. The lateral aspect of the duodenal bulb was smoothly indented, presumably by the gallbladder.

The infection was treated with enteric-coated tablets of methylrosaniline chloride (60 mg. three times a day) for one month. Unfortunately, follow-up study was not possible.

CASE 3.—A man aged 34 who had been in the United States for three months was admitted to the second medical service (Dr. I. Snapper) of Mount Sinai Hospital because of abdominal distention of three years' duration. He was born in Germany and had lived in Shanghai from 1939 to 1948.

Soon after his arrival in Shanghai in 1939, he suffered from frequent soft bowel movements, on the average of six a day, accompanied by abdominal distention and dull periumbilical pain. There was occasional crampy pain in the right upper quadrant of the abdomen, radiating to the back. In 1944 he became jaundiced during an epidemic of hepatitis in Shanghai, and he had weakness, nausea, fever and clay-colored stools. In September 1946 severe diarrhea developed, and he experienced twenty to twenty-five nonbloody movements daily. On routine examination of the stool ova of C. sinensis were found, and the infection was treated with methylrosaniline chloride. It was stated that the patient had gallbladder disease as well. At that time the white blood cell count was 20,000, with 20 per cent eosinophils. After his arrival in the United States he continued to experience abdominal distention and cramps in the lower part of the abdomen. He stated that in Shanghai he had eaten fresh water fish regularly and that clonorchiasis was widespread there.

Physical examination revealed a well developed and well nourished man. The liver was palpable 1 to 2 fingerbreadths below the costal margin. The spleen was not felt. The blood pressure was 118 systolic and 72 diastolic.

The hemoglobin concentration of the blood was 17.0 Gm. The white blood cell count was 11,400. The differential count revealed 55 per cent polymorphonuclear neutrophils, 31 per cent lymphocytes, 10 per cent eosinophils, 2 per cent monocytes and 2 per cent basophils. The urine contained 2 to 6 white blood cells per high power field, and there was no bile. The urine urobilinogen determination was 1:64. The erythrocyte sedimentation rate was 15 mm. per hour (Westergren). The stool was guaiac negative and contained ova of C. sinensis. The fasting blood sugar level was 84 mg. and the urea nitrogen was 23 mg. per hundred cubic centimeters. Liver function tests revealed the following: sulfobromophthalein sodium, no retention; cephalin flocculation, 1 plus. The serum cholesterol determination was 219 mg. per hundred cubic centimeters. Blood agglutination reactions for typhoid, Salmonella and Shigella paradysenteriae were negative. The sigmoidoscope was passed a distance of 25 cm., and the mucosa was found to be normal.

A course of chloroquine diphosphate (in a dosage of 500 mg. a day) was given for four weeks, and two stool examinations toward the end of the treatment were negative for ova of C. sinensis. However, a subsequent stool examination, one month after treatment, revealed their presence.

CASE 4.—A white girl 4 years of age was admitted to the pediatric wards of Mount Sinai Hospital with a main complaint of nodding of the head of six months' duration. She had been born in Shanghai and had lived there until coming to the United States three months previously. She had had dysentery at 2 years of age. Six months prior to her admission to the hospital, rotation and roving of the eyes had developed. Later, she exhibited a peculiar mannerism of repeatedly dropping her head and raising it every ten or fifteen minutes, mainly in the mornings. There was a history of retarded development. She had no symptoms referable to the gastrointestinal tract. A routine stool examination before entry revealed ova of C. sinensis.

Physical examination revealed a child without distress. There was an erythematous rash on the extensor surface of the arms and thighs. The liver and spleen were not palpable.

The hemoglobin concentration of the blood was 12.4 Gm. per hundred cubic centimeters, and the white blood cell count was 7,400 with 46 per cent polymorphonuclear neutrophils, 48 per cent lymphocytes, 3 per cent monocytes and 3 per cent eosinophils. The urine contained an occasional pus cell. The stool culture showed atypical Escherichia coli. The serum agglutination tests were negative for B. abortus and B. melitensis. On microscopic examination, the stool and biliary drainage revealed ova of C. sinensis. The blood urea nitrogen determination was 11 mg. and the serum cholesterol was 420 mg. per hundred cubic centimeters, with cholesterol esters 250 mg. per hundred cubic centimeters. The cephalin flocculation reaction was negative.

The head nodding was not present during the hospital stay. A ten day course of enteric-coated tablets of methylrosaniline chloride (10 mg. three times a day) was given. Immediately following the treatment, two stool examinations failed to reveal the presence of ova of C. sinensis.

## COMMENT

Each of the foregoing cases was considered as an example of mild infection with C. sinensis. Three of the patients had symptoms referable to the upper part of the abdomen that probably were the result of hepatic, biliary or duodenal dysfunction due to the presence of adult flukes and ova. One patient, a child (case 4), had no gastrointestinal symptoms. It is well known that the majority of infected persons harbor few worms and present few symptoms. However, in heavier infections, perhaps as in cases 1, 2 and 3, there may be an irregular appetite, pain in the upper part of the abdomen, attacks of diarrhea and constipation, and loss of weight. In case 1 a prolonged low grade fever was the chief symptom. Chronic cholecystitis is often suspected and is not uncommon.[12] In Howard's case[3] calculous cholecystitis was present.

In advanced stages of the disease icterus, ascites and hepatosplenomegaly, the classic observations in hepatic cirrhosis, may appear. Episodes of jaundice may occur on the basis of biliary obstruction from adult worms in the common duct or as a result of attacks of acute cholangitis or hepatitis. Night blindness has been reported and is probably due to an associated vitamin A deficiency, as seen in chronic hepatic disease. In Crawford's case[4] pulmonary infiltrations consistent with a diagnosis of Löffler's syndrome were observed. Eosinophilia, noted in 3 of our cases, is generally present and is variable in amount. The eosinophil count may exceed 50 per cent. Leukocytosis is commonly observed, especially in early cases.[4]

The diagnosis is verified by the finding of the characteristic ova of C. sinensis in the feces or in the fluid obtained by duodenal drainage.[1c] In the search for ova concentration of the stool should be attempted by sedimentation technics, since the ova are heavy and might be missed in material obtained by flotation.

The chemotherapy of clonorchiasis is not particularly satisfactory, because the parasite is difficult to eliminate with the available drugs. Methylrosaniline chloride is the drug of choice in the treatment of early cases.[1c] It is given to adults in doses of 60 to 120 mg. three times a day for periods of two to four weeks in the form of enteric-coated tablets. In case 1, with a careful follow-up period of three months, the use of this drug was followed by clinical improvement, a decrease in eosinophilia and temporary disappearance of Clonorchis ova from the stools. In cases resistant to several courses of methylrosaniline chloride, a course of intravenous injections of sodium antimonyl tartrate may be tried.[1c] The drug is given intravenously on alternate days in the form of a freshly prepared 2 per cent solution. The initial dosage of 60 mg. should be doubled on the third day (120 mg.), and then this dosage should be injected every other day until a total of 1.3 to 1.8 Gm. has been given. We have had no personal experience with this method of treatment.

In 1 instance, case 3, chloroquine diphosphate was used to determine whether or not it had any clonorchicidal value. This drug is heavily concentrated in the liver and, in addition to its antimalarial activity, is said to possess amebacidal activity in amebic hepatitis. It failed to eliminate Clonorchis ova from the stools, although it was given for a period of three weeks.

### SUMMARY

1. Four cases of infection with Clonorchis sinensis were observed in white emigrants from Shanghai, China, who were residing in New York City.

2. A brief résumé of the epidemiologic and clinical features of this disease is presented.

3. Chloroquine diphosphate was used in 1 patient but had no influence on the infection with C. sinensis.

# SEPTICEMIA DUE TO BACTEROIDES

## Aureomycin Hydrochloride Therapy in Two Cases Due to Bacteroides Funduliformis

LEON V. McVAY Jr., M.D.
FRANCES GUTHRIE
and
DOUGLAS H. SPRUNT, M.D.
Memphis, Tenn.

A review of the literature reveals that Bacteroides-caused infections in human beings are not infrequent. It is our impression that the incidence of infections and septicemia due to Bacteroides is probably much greater than that reported. These organisms are normal inhabitants of the mucous membranes of the body, and injury of mucosal surfaces, such as may occur in a ruptured appendix, may result in localized or widespread infections due to Bacteroides. If the blood stream is invaded, septicemia may result with metastatic abscesses, and the outlook becomes exceedingly grave.

Eighteen cases of Bacteroides-caused infection have been observed at John Gaston Hospital in the past five years. This report is concerned only with 2 cases of septicemia due to Bacteroides funduliformis treated with aureomycin hydrochloride.

Castellani and Chambers[1] in 1919 proposed the designation *Bacteroides* for a large group of anaerobic, nonsporulating bacilli. The 1939 edition of "Bergey's [illegible] Bacteriology"[2] classified the gram-negative members of the anaerobic, non-spore-forming bacilli under the genus Bacteroides.

The prognosis of septicemia due to Bacteroides is extremely poor. In 1941 Brown, Williams and Herrell[3] reported the recovery of 1 of 15 patients with septicemia due to B. funduliformis at the Mayo Clinic. In an additional 10 cases of septicemia due to Bacteroides collected from the literature by Thompson and Beaver[4] only 4 patients recovered. In 1947 Ruys[5] related the histories of 4 patients with septicemia due to Bacteroides; only 1 survived after a prolonged febrile illness. Six cases of septicemia due to Bacteroides have been observed at John Gaston Hospital in the past five years. In the first 4 the patients died in spite of chemotherapy, antibiotics and supportive treatment. The last 2 recovered under treatment with aureomycin hydrochloride.

### REPORT OF CASES

CASE 1.—*History.*—A Negro woman aged 69 was hospitalized Dec. 21, 1948 with a history of purulent nasal discharge, cough, headache, sore throat, chills, fever, nausea and vomiting of three weeks' duration. The nasal discharge had been excessive, thick and greyish yellow, and it was intermittently streaked with blood. Chills and fever occurred daily. There was no history of abdominal pain, but malaise and lethargy were noted.

*Physical Examination.*—The temperature was 103.4 F., the pulse rate 105 per minute, the respiratory rate 18 per minute and the blood presure 180 mm. of mercury systolic and 120 mm. diastolic. The heart was enlarged. The abdomen was distended

5. Ruys, A. C.: Bacteroides Funduliformis, J. Path. & Bact., **59**: 313-316, 1947.

and tympanitic but not tender. There was no abdominal mass. The day after admission severe pain developed in the right upper quadrant with tenderness in that area. Moderate icterus of the scleras was observed. Five days after admission the icterus was pronounced, the abdomen distended, peristalsis absent and rebound tenderness decided. The patient continued to have a septic temperature. The liver was palpable 2 fingerbreaths below the costal margin on the right side and was tender. Slight nuchal rigidity was noted.

*Treatment and Course.*—Two blood cultures for B. funduliformis were positive. The patient had shown no response to treatment with penicillin, sulfadiazine or streptomycin. It was decided to investigate the therapeutic effect of aureomycin. Sensitivity tests revealed that the growth of B. funduliformis from the patient's blood was not inhibited by penicillin in a concentration of 2 units per cubic centimeter, by streptomycin in a concentration of 250 micrograms per cubic centimeter or by sodium sulfadiazine in a concentration of 125 mg. per hundred cubic centimeters, but growth was entirely inhibited by aureomycin hydrochloride in a concentration of 13 micrograms per hundred cubic centimeters.

Oral administration of aureomycin was impossible in this case because of the existing ileus. Aureomycin therapy was begun eleven days after admission. The agent was given intramuscularly in distilled water to which procaine hydrochloride had been added. In view of the Herxheimer-like reactions described by Spink and associates [6] in the treatment of brucellosis, it was decided to give small initial doses. The following dosage was given: 750 mg. in divided doses during the first twenty-four hours, 2 Gm. during the second twenty-four hours, 4 Gm. during the third twenty-four hours and 5 Gm. a day thereafter. With the institution of aureomycin therapy, all other antibiotics and chemotherapy were discontinued. No reaction occurred to this medication.

Fifteen days after admission the abdomen was soft, peristalsis was audible, the liver was barely palpable and abdominal tenderness had essentially disappeared. Seventeen days after admission (forty-eight hours after use of the Wangensteen suction tube was discontinued) oral administration of aureomycin was begun. However, the intramuscular route was resumed when it was observed that the blood level of aureomycin had fallen 60 per cent.

On the twenty-fourth day after admission of the patient there developed acute myocardial decompensation with decided dyspnea, tachycardia, pulmonary edema, hepatomegaly and edema of the lower extremities. Excellent response was obtained with digitalization, ammonium chloride, mercurial diuretics and the Karell diet. By the twenty-eighth day all evidence of decompensation had disappeared. On the twenty-sixth day the dosage of aureomycin hydrochloride was reduced to 500 mg. orally every six hours.

The septic type of temperature disappeared on the fourth day of aureomycin therapy, and the temperature gradually returned to normal. From the twenty-sixth day after admission the patient had no complaints aside from severe weakness and lethargy. She had a completely negative attitude. It was considered that this was the result of a severe infection superimposed on already existent cerebral arteriosclerosis. The spinal fluid was clear and contained no cells. Neurologic examination revealed normal conditions. Therefore the Levine tube was repassed on the thirty-first day and formula feeding was resumed. Supportive treatment consisted of repeated small blood transfusions, vitamins, liver extract, ferrous sulfate and intravenous amigen.®

In view of ten negative blood cultures, together with clinical and physical evidence of improvement, aureomycin therapy was discontinued after the patient had received 75.45 Gm. of the drug. Following this, the temperature rose to show a daily spike of about 101 F. for the ensuing six days. It then became normal and remained so. Because of the extremely low plasma potassium level (3 milliequivalents per liter), 3 Gm. of potassium chloride were given daily beginning on the forty-second day.

On the forty-sixth day there was striking mental improvement. From this date the patient was afebrile, talkative, well oriented and desirous of going home. The patient was discharged on the fifty-ninth day after admission.

*Laboratory Data.*—The white blood cell count varied from 35,100 to 11,250 and the red from 3,150,000 to 4,850,000 per cubic millimeter; the hemoglobin level from 8.5 to 12.5 Gm. per hundred cubic centimeters; the hematocrit reading from 21 to 41 per cent; the one minute serum bilirubin determination from 12.2 to 0.8 mg. and the total serum bilirubin from 19.4 to 1.0 mg. per hundred cubic centimeters; the twenty-four hour urine urobilinogen level from 64.6 to 6.6 Ehrlich units; sulfobromophthalein sodium retention from 32 to 7 per cent; total plasma protein from 5.8 to 6.6 Gm. with albumin from 2.9 to 3.6 Gm. and globulin from 2.8 to 3.0 Gm. per hundred cubic centimeters; the sedimentation rate (Wintrobe) from 70 to 18 mm. in an hour; nonprotein nitrogen from 93 to 28 mg. per hundred cubic centimeters. Repeated spinal fluid examinations were normal; urinalyses revealed 1 plus albumin. The highest blood aureomycin level obtained was 8 micrograms per hundred cubic centimeters.

CASE 2.—*History.*—A Negro woman aged 35 was hospitalized Jan. 25, 1949 with a history of illness for three weeks. The onset was marked by upper abdominal pain, nausea and vomiting. The pain lasted four to five days, but the vomiting persisted. Shortly after the onset of this illness, intermittent chills with a high elevation of temperature were noted. For two weeks prior to admission a nonproductive cough had been present. For one week prior to admission the patient had been given 300,000 units of penicillin daily by her physician.

*Physical Examination.*—Examination on admission revealed a temperature of 99.6 F., a pulse rate of 110 per minute, a respiratory rate of 28 per minute and blood pressure of 120 mm. of mercury systolic and 86 mm. diastolic. There was a mild hyperemia of the nose and throat. There was moderate rigidity in the right upper quadrant of the abdomen and in the epigastric area. Tenderness was noted in these areas and in the right lower quadrant. The liver, kidney and spleen could not be palpated. There was no abdominal mass. Pelvic examination revealed essentially normal conditions.

*Treatment and Course.*—Shortly after admission the patient became icteric; the liver became palpable and tender. In spite of massive doses of penicillin and streptomycin, together with repeated blood transfusions, the patient had a septic type of temperature with a daily spike to 105 or 106 F. Two positive blood cultures for Streptococcus fecalis and for B. funduliformis were obtained. At the height of fever, a third blood culture was positive for B. funduliformis only. On the fifteenth day after admission, penicillin and streptomycin therapy were discontinued; aureomycin therapy was instituted following sensitivity tests, which showed that the growth of B. funduliformis was not inhibited by penicillin 2 units per cubic centimeter or by streptomycin 250 micrograms per cubic centimeter or by sulfadiazine 125 mg. per hundred cubic centimeters but was inhibited by aureomycin hydrochloride 12 micrograms per cubic centimeter. It had previously been shown that growth of Str. fecalis was inhibited by penicillin 0.12 units per cubic centimeter or by streptomycin 1.06 micrograms per cubic centimeter.

The patient was given 750 mg. of aureomycin hydrochloride by mouth in divided doses during the first twenty-four hours, 2 Gm. during the second twenty-four hours, 4 Gm. during the third twenty-four hours and 5 Gm. a day thereafter. She was also given a high protein and high carbohydrate diet with supplementary vitamins. The patient responded dramatically. She became afebrile on the fifth day of aureomycin therapy and remained so. Studies of the blood chemistry prior to the institution of aureomycin therapy revealed a pronounced reduction of plasma potassium (3.3 milliequivalents per liter); therefore 3 Gm. of potassium chloride were given daily for four days. Although nausea persisted in association with the administration of aureomycin, the persistent vomiting disappeared. Dehydration, sweating, lethargy, weakness and anorexia rapidly subsided. On the eighth day of aureomycin therapy the dosage was reduced to 4 Gm. The following day the twenty-four hour dosage was further reduced to 2 Gm. On the fourteenth day administration of this antibiotic was discontinued, as the patient was asymptomatic, showed no physical evidence of disease, had been afebrile for nine days, and had shown five negative blood cultures. The patient was discharged on the thirty-sixth day after admission.

---

*Laboratory Data.*—The white blood cell count varied from 26,900 to 6,550 and the red from 2,160,000 to 3,870,000 per cubic millimeter; the hemoglobin level from 7.5 to 12 Gm. per hundred cubic centimeters; the hematocrit reading from 22 to 34 per cent; the twenty-four hour urine urobilinogen level from 47.6 to 2.5 Ehrlich units; the one minute serum bilirubin determination from 0.3 to 1.5 mg. and the total serum bilirubin from 2.8 to 0.9 mg. per hundred cubic centimeters; sulfobromophthalein sodium retention from 30 to 8 per cent; the total plasma protein from 6.7 to 8.2 Gm. with albumin from 2.7 to 3.2 Gm. and the globulin from 5.0 to 3.2 Gm., per hundred cubic centimeters; the cephalin flocculation reading from 4 plus to 1 plus at twenty-four hours and from 4 plus to 1 plus at forty-eight hours; the sedimentation rate (Wintrobe) from 76 to 23 mm. in one hour. Repeated urinalyses were normal. The nonprotein nitrogen level remained about 30 mg. per hundred cubic centimeters. A spinal fluid examination was normal. The highest aureomycin blood level was 8 micrograms per hundred cubic centimeters.

### COMMENT

Bacteroides infections are more frequent than is generally recognized. Eighteen cases have been observed at the John Gaston Hospital in the past five years. Six of these were cases of septicemia due to Bacteroides. It would appear that many cases are not diagnosed because of the scarcity of information concerning these organisms and because of the failure to look for anaerobic bacteria. Septicemia due to Bacteroides, especially the funduliformis type, is exceedingly severe, with the majority terminating fatally. Until the present there has been no specific or adequate therapy for this condition. The excellent response to aureomycin hydrochloride therapy in 2 recent cases of septicemia due to B. funduliformis is therefore most encouraging.

In both cases supportive therapy included repeated small blood transfusions, multivitamins, ferrous sulfate, liver extract and a special diet high in protein and carbohydrate. The blood chemical studies in both instances revealed a pronounced reduction in the plasma potassium level, which was corrected by the oral administration of potassium chloride.

In vitro sensitivity tests demonstrated that growth of the B. funduliformis isolated from the patient's bloodstream would not be affected greatly by sulfadiazine, penicillin or streptomycin therapy. However, growth was inhibited by aureomycin hydrochloride. In vitro studies failed to show the development of resistant organisms after prolonged treatment with aureomycin. Other than moderate nausea, significant toxic reactions to the drug were not observed.

### SUMMARY

Two cases of septicemia due to Bacteroides funduliformis have been successfully treated with aureomycin hydrochloride. The following dosage was used: 750 mg. in the first twenty-four hours, 2 Gm. in the second twenty-four hours, 4 Gm. in the third twenty-four hours and 5 Gm. a day thereafter until definite evidence of recovery was noted.

Significant toxic reactions were not observed in the use of aureomycin hydrochloride.

---

# MATERNAL DEATHS FROM COCCIDIOIDOMYCOSIS

LEROY E. SMALE, M.D.
and
J. W. BIRSNER, M.D.
Bakersfield, Calif.

Disseminated coccidioidomycosis as a cause of maternal deaths has not been reported previously. We are reporting 4 fatal cases, while a fifth case is still being observed. Unquestionably, other fatal and unrecognized cases have occurred in this endemic area, or the subjects have migrated to other areas, with a final diagnosis of maternal death due to meningitis of unspecified cause.

In Kern General Hospital for the year 1948, there were 4 maternal deaths in 2,410 deliveries; of these deaths, 3 were due to disseminated coccidioidomycosis. It is interesting to note that during the same year no mothers died of tuberculosis, either in this hospital or in Kern County. We feel that other cases will be discovered and reported and that the pathogenesis of disseminated coccidioidomycosis as a fatal complication of pregnancy and as a cause of maternal death will become well known.

### REVIEW OF LITERATURE

An exhaustive search of the literature of coccidioidal granuloma has failed to lead to the discovery of a single publication concerning disseminated coccidioidomycosis occurring during pregnancy. Forbus and Bestebreurtje[1] published a comprehensive review of the literature with an excellent exposition of the pathogenesis of coccidioidomycosis. In 1936, Abbott and Cutler[2] published a review of the pathologic studies of chronic coccidioidal meningitis and presented a bibliography of all reported cases of coccidioidal meningitis. They divided meningitis into two general forms: (1) meningitis associated with granulomas in other organs, and (2) primary chronic coccidioidal meningitis. Three of our 4 cases of coccidioidal meningitis fall into the first category and 1 in the second.

### REPORT OF CASES

CASE 1.—E. N., a 37 year old Negro gravida II, para I, was admitted to the hospital on April 17, 1944, complaining of pain in the abdomen and in the right hip. An abscess on her right hip was finally diagnosed, and incision and drainage was done on April 26. Labor began on May 9, and she delivered a stillborn infant (sex unnoted) spontaneously. The heart tones disappeared during labor. Her postpartum condition became critical, and she died three days following delivery.

*Laboratory Data.*—Results of Mantoux, coccidioidin and brucellergin skin tests were negative. Biopsy material from the abscess showed Coccidioides imitis. Examination of the spinal fluid revealed 810 cells per cubic millimeter, 95 per cent of which were polymorphonuclear leukocytes. No serologic tests were performed. A roentgenogram showed an osteolytic area

---

The complement fixation and precipitin tests were done in the laboratory of Dr. C. E. Smith, School of Medicine, Stanford University.

Dr. Ralph C. Benson, University of California Hospital, and Dr. B. O. Raulston, Dean, School of Medicine, University of Southern California, assisted in the preparation of this paper.

Leroy E. Smale, M.D., was formerly Chief Resident of Obstetrics and Gynecology on the service of O. Donovan Johnson, M.D., Kern General Hospital, and is now Associate attending in Obstetrics and Gynecology at Kern General Hospital.

J. W. Birsner, M.D., was formerly Chief Resident of Radiology, Kern General Hospital, and is now attending in Radiology at Kern General Hospital.

[1] Forbus, W. D., and Bestebreurtje, A. M.: Coccidioidomycosis: A Study of Ninety-Five Cases of the Disseminated Type with Special Reference to the Pathogenesis of the Disease, Mil. Surgeon **99**: 653-719 (Nov.) 1946.

[2] Abbott, K. H., and Cutler, O. I.: Chronic Coccidioidal Meningitis, Review of Literature and Report of Seven Cases, Arch. Path. **21**: 320-330 (March) 1936.

in the crest of the right ileum. The autopsy disclosed microscopic and macroscopic evidence of disseminated coccidioidomycosis in the skin, lungs, mediastinal nodes, meninges, spleen, pancreas, kidneys, thyroid and bones. Neither the fetus nor the placenta were mentioned in the clinical chart or in the autopsy report.

CASE 2.—M. E. B., a 31 year old white gravida III, para III, was admitted to the hospital on Jan. 29, 1948, forty-eight hours post partum. Her past history indicated that she had had "erythema nodosum due to Coccidioides" in January 1946.

She had been admitted to another hospital with a history of influenza for one week prior to delivery and with complaints of severe headache and soreness of the neck for twenty-four hours. At the time of delivery, her temperature was 102 F. and she complained of a stiff neck. Her spontaneous delivery was uneventful. Examination of spinal fluid shortly before her transfer showed 573 white blood cells per cubic millimeter, with 60 per cent polymorphonuclear cells, 34 per cent lymphocytes and 6 per cent eosinophils. At the time of admission, examination showed a somewhat confused woman whose neck was stiff and whose uterus extended 12 cm. above the symphysis.

The patient's course in the hospital was marked by episodes of unconsciousness, from which she would more or less completely recover. She became irrational and disoriented after about a month of hospitalization. During this time, she received both penicillin and streptomycin in large doses. Two cutaneous facial ulcerative lesions appeared from which biopsy specimens were taken. They showed cutaneous coccidioidomycosis.

A noteworthy description by the neurologic consultant, Dr. J. M. Nielsen, on March 2, 1948, is quoted in part: "Her pupils were large, the left being larger than the right. The left pupil reacted poorly to light. Both disks were choked. There was decided rigidity of the neck and pronounced hypersensitivity throughout the body. There was complete loss of sphincter control. Both legs were paralyzed and one drawn up in flexion. There was some loss in strength of both upper limbs. Quick response to pinprick existed throughout the body, including the fourth and fifth sacral segments, which indicated that the lateral spinothalamic tracts were intact. However, the paralysis and the loss of sphincter control indicated that the central portion of the spinal cord was out of function. This constituted a meningeal picture." The patient died on April 18.

*Laboratory Data.*—On January 29, a spinal tap showed 573 white blood cells per cubic millimeter, with 60 per cent polymorphonuclear cells, 34 per cent lymphocytes and 6 per cent eosinophils. Examination of the spinal fluid on February 4 showed 88 white blood cells, with 53 per cent polymorphonuclear cells and 47 per cent lymphocytes. On February 26, a roentgenogram of the lungs and the skull showed no abnormalities. The spinal fluid contained 290 white blood cells, with 70 per cent polymorphonuclear cells and 30 per cent lymphocytes. On February 27 a biopsy of the lesion of the right nasolabial fold revealed disseminated coccidioidomycosis. On February 28, the results of the serum complement fixation tests for Coccidioides were strongly positive through dilution 1:4. No precipitins were noted. From the observations it was concluded that an old coccidioidal infection existed, with the notation that coccidioidal meningitis has been known to occur with low titer serologic reactions.

On March 13 the results of complement fixation tests of the blood serum were positive through dilution 1:4. It was noted that, while the titer of complement fixation was not high, in conjunction with the increased spinal fluid cell count it would seem to establish the diagnosis of coccidioidal meningitis.

On March 24 the complement fixation titers of the blood serum were weakly positive through dilutions 1:4. It was concluded that the continued high cell count was diagnostic, with the comment that some patients with meningitis have low complement-fixing titers. On April 14 the spinal fluid cell count was 25 white blood cells, with 60 per cent polymorphonuclear cells and 40 per cent lymphocytes. Results of all serologic tests of the spinal fluid were negative. Permission for autopsy was refused.

*Infant.*—The infant was a well developed term baby who gained well from birth.

CAES 3.—B. G. S., a 28 year old Negro gravida II, para I, whose expected date of confinement was Sept. 27, 1948, was admitted to the hospital on July 23, complaining of a headache of twelve hours' duration. Examination revealed only a temperature of 101 F. and a stiff neck. All reflexes were normal. Examination of the spinal fluid showed 1,060 white blood cells per cubic millimeter, with 94 per cent polymorphonuclear cells. Her white blood cell count was 9,000, with a normal Schilling count. A roentgenogram of the chest taken on August 2 showed "confluent bronchopneumonia, cause unspecified." On August 4, after her membranes ruptured spontaneously, she delivered a normal premature male infant weighing 4 pounds 8 ounces (2,041 Gm.). The patient died the following day. Pathologic examination of the placenta revealed no abnormalities.

In summary, postmortem examination proved the existence of a disseminated form of coccidioidomycosis involving the lungs, mediastinal nodes, meninges, spleen, adrenals and kidneys. Results of coccidioidin precipitin tests and complement fixation tests were strongly positive and were interpreted as indicative of a "progressive disseminated coccidioidal infection."

*The Infant.*—The infant was an apparently normal premature male who gained until his twenty-fifth day of life, at which time he vomited a feeding and aspirated some of the formula. He died within a few hours. An autopsy showed atelectasis, prematurity and bronchopneumonia. Postmortem complement fixation tests for coccidioidomycosis showed weak titers, which were interpreted as evidence of passive transfer of antibodies. No microscopic or macroscopic evidence of any form of coccidioidomycosis was found.

CASE 4.—E. M., a 34 year old white gravida V, para I, with three abortions, was admitted to the hospital on Aug. 24, 1948, and had complained of a stiff neck and frontal headache for one day. On April 16, she was noted to have had a positive tuberculin (3 plus) and a negative coccidioidin skin reaction. A chest film showed "increased bronchial markings consistent with pulmonary coccidioidomycosis." The patient's last menstrual period was in February 1948. The results of the physical examination were essentially normal except for a positive Babinski sign on the right and a stiff neck. While in the hospital, she continued to complain of a severe headache, which was occasionally accompanied with vomiting. On October 2, her pregnancy terminated in a spontaneous delivery of an apparently normal mature male infant. The patient's condition did not improve, and she was discharged to private care on November 4.

*Laboratory Data.*—On August 24, a lumbar puncture revealed 124 cells, with 21 polymorphonuclear cells and 72 lymphocytes. On August 28 the result of the coccidioidin skin test was strongly positive; the result of the complement fixation test was negative but of the precipitin test positive through dilutions of 1:10. The conclusion drawn from this test was that there was a "currently active coccidioidal infection acquired in the not too distant past."

The roentgenogram of the chest on August 30 was normal. On September 13 a spinal puncture showed a cell count of 140, with 2 per cent polymorphonuclear cells and 98 per cent lymphocytes. On September 22, the result of the complement fixation test in dilution of 1:2 was positive. The reaction to the precipitin test was strongly positive undiluted.

On October 2, the spinal puncture showed 157 cells, with 8 per cent polymorphonuclear cells and 92 per cent lymphocytes. The complement fixation reaction of the blood serum was strongly positive in dilution of 1:2 and positive in dilution of 1:4. The reaction to the precipitin was positive through a dilution of 1:10. On November 3, the result of the complement fixation test was positive in dilutions through 1:16 and the precipitins were positive through dilutions of 1:40. On November 4, the lumbar puncture showed 129 cells, with 8 per cent polymorphonuclear cells and 92 per cent lymphocytes.

*Infant.*—The child was an apparently normal healthy male who gained well during his hospital stay. A complement fixation test made at birth from the cord blood showed a positive reaction through a dilution of 1 : 4.

On November 5 the reaction was doubtful in dilution of 1 : 2. This was interpreted as being suggestive of passive transfer of antibodies through the placenta. Pathologic examination of the placenta showed no evidence of coccidioidal granuloma.

CASE 5.—B. T. B., a 27 year old Negro gravida IV, para II, with one abortion, was first seen in the Prenatal Clinic on December 10, during her thirty-ninth week of gestation. On December 25, she returned to the Emergency Clinic complaining of weakness in the left arm and pain in the left side of the chest for two weeks.

*Physical Examination.*—The blood pressure was 95 systolic and 60 diastolic. The patient's neck was stiff to motion in any direction. Her lungs produced only a few rales in both bases. The uterine fundus was about 4 cm. below the costal margin, and the fetal heart tones were present. She was admitted to the hospital with a diagnosis of "possible poliomyelitis." Her course in the hospital was marked by slowly developing respiratory distress and coma. Between December 26 and December 27, the fetal heart tones disappeared, and the patient died undelivered on December 27.

*Laboratory Data.*—A roentgenogram of the chest, May 27, 1947, was normal. The Kahn reaction of the blood was positive. On Dec. 10, 1948 the hemoglobin was 10.5 Gm.; the blood type was revealed as Rh positive, and the Kahn reaction was positive. From a roentgenogram of the chest, reported as "suspicious," pathologic changes in the lungs were suspected.

On December 24, a roentgenogram of the chest showed "possible miliary tuberculosis."

*Autopsy.*—Postmortem examination of the patient revealed previously unsuspected disseminated coccidioidomycosis of the lungs, spleen, kidneys and adrenals. The meninges were not diseased. Examination of the tubes, ovaries, uterus and placenta showed no abnormalities. The fetus showed no evidence of coccidioidomycosis.

COMMENT

One of us (J. W. B.) started this study when he discovered that in case 1 inadequate analysis had been made at the postmortem examination. We were struck with the possibility that placental coccidioidal granuloma might occur with subsequent infection of the fetus. We are familiar with the similarity between coccidioidal granuloma and tuberculosis, and we are familiar with the work of Loewenstein[3] in congenital tuberculosis. Loewenstein, through injection of maternal and fetal (cord) blood into guinea pigs, conclusively demonstrated bacteremia of Mycobacterium tuberculosis in both mother and child. Tuberculosis of the placenta accounted for the bacteremia.

Coccidioidomycosis differs from tuberculosis in that the kidneys, the fallopian tubes and the prostate are the only portions of the genitourinary tract observed to have been involved. There was an absence of the disease in the genital tract in cases 1, 2, 3 and 5. All the other organ systems except the gastrointestinal tract were extensively diseased. It appears that this feature, in the light of the foregoing statement, carries considerable significance. If the uterus and endometrium have never been involved in coccidioidomycosis, then congenital coccidioidomycosis, unlike congenital tuberculosis, probably has never been observed.

In cases 2, 3 and 4, strong evidence exists in the weak and progressively diminishing fetal coccidioidin complement-fixing titers, in the normal placentas and in the normal growth and development of the infants, that a granuloma did not develop in the placenta. Consequently, congenital coccidioidomycosis did not become manifest. There was no postmortem evidence of congenital transmission in case 5.

Case 3 is included in this paper because, in our experience, primary coccidioidal meningitis has been a uniformly fatal disease despite all treatment, and it is expected that the patient in this case, too, will die. A review of the literature substantiates this impression.

It is recommended that, in a known endemic area for coccidiodomycosis, all pregnant patients with symptoms of the upper part of the respiratory tract have skin tests and be carefully followed for possible dissemination. It is also recommended that all pregnant patients with signs and symptoms of meningeal involvement or meningitis be carefully studied for infection with Coccidioides.

SUMMARY AND CONCLUSIONS

Disseminated coccidioidomycosis in pregnancy, fatal in 4 cases reported herein, in 3 with coccidioidal meningitis and 1 without meningeal involvement, is reported as a new cause of maternal deaths.

No evidence exists that coccidioidomycosis imitates tuberculosis with respect to congenital transmission.

ADDENDUM

Dr. L. H. Winer, Beverly Hills, Calif., permitted us to examine histologically a human placenta that contained typical granulomas of coccidioidomycosis. We have been unable to learn any further details of the subject or her infant.

# Clinical Notes, Suggestions and New Instruments

## RADIOACTIVE IODINE ($I^{131}$) IN THE DIAGNOSIS OF LINGUAL THYROID

HERMAN M. NACHMAN, M.D.
VERNON CRAWFORD
and
I. A. BIGGER, M.D.
Richmond, Va.

The specific affinity of functioning thyroid tissue for iodine is the rationale for the use of radioactive iodine in tracer doses to study iodine metabolism and the physiology of the human thyroid gland. The pioneer work of Hamilton[1] and Hertz[2] initiated this type of investigation.

Radioactive iodine was given to a girl 11 years of age in tracer amounts to aid in the preoperative evaluation of a suspected lingual thyroid, subsequently proved to be such microscopically and by radioautograph. This case is reported as another example of the value of radioactive tracer technics in the surgical management of thyroid abnormalities. Feitelberg and associates[3] have reported the use of radioactive iodine in the study of a lingual thyroid, but their subject did not have operative intervention.

Persistence of thyroid tissue at the site of its origin, the foramen cecum at the base of the tongue, is an uncommon

---

Graduate student, Rouss Physics Laboratory, University of Virginia (Mr. Crawford).

anomaly which is amenable to surgical treatment. Montgomery[4] in a review of the literature in 1936 found 231 reports on lingual thyroid but considered only 144 as authentic. He credited the first authenticated case to Bernays (1888). Buckman[5] reported 242 such cases in a similar review of the literature in 1936. The recent review of Goetsch[6] reported 3 cases of lingual thyroid substantiated by histologic section. The reviews of Montgomery and Buckman include excellent discussions of the historic aspect of lingual thyroid, the development of the tongue and the thyroid gland, and the embryologic malformation which results in the development of the lingual thyroid.

The present report purposely excludes these aspects of lingual thyroid and directs attention to the use of radioactive iodine and the radioactive tracer technic as an aid in the preoperative evaluation of this thyroid anomaly.

## REPORT OF CASE

P. P., a white girl, 10 years of age, was admitted to the Medical College of Virginia, Hospital Division, on Aug. 2, 1948 complaining of a lump in the tongue. When the patient was 4 years of age, a small "cyst" was noted at the base of the tongue during tonsillectomy. The parents were advised to keep the mass under surveillance and to return for consultation if the mass increased in size or began to give symptoms of obstruction. The patient remained asymptomatic for a period of approximately six years, but about six months prior to admission the child's mother noticed that she talked "as if she had something in her mouth." The patient had slight difficulty in swallowing, but there was no serious dysphagia.

On physical examination, the patient was well developed for her age and was alert. The observation of greatest significance was an oval red mass measuring approximately 3 by 2 by 2 cm. at the base of the tongue at the site of the foramen cecum. When the tongue was protruded, the mass was easily visualized, being large enough to partially occlude the pharynx. The thyroid gland was not palpable in the normal position, and each cervical tracheal ring could be easily felt; so it was assumed that the entire thyroid had remained at the base of the tongue. The remainder of the physical examination revealed essentially normal conditions.

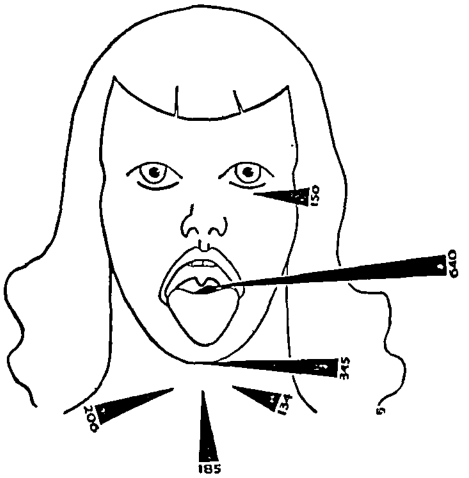

Fig. 1.—Diagrammatic illustration of lingual thyroid and concentration of radioactive material (expressed as counts per minute).

The results of the blood count, urinalysis and cholesterol determinations were all within normal limits. Two basal metabolic studies gave values of plus 24 and minus 10 per cent. Both were considered unsatisfactory due to the patient's difficulty in breathing while the test was being performed. A roentgenogram of the chest disclosed no abnormalities.

A tentative diagnosis of lingual thyroid was made, and surgical removal was advised. Although no thyroid gland was palpable in the normal position, this could not be considered conclusive evidence that none existed at that site; and it was important to determine whether the lingual mass contained all of the functioning thyroid tissue. This problem could have been solved by surgical exploration of the thyroid area, but this proved unnecessary following the use of radioactive iodine ($I^{131}$) in the following manner.

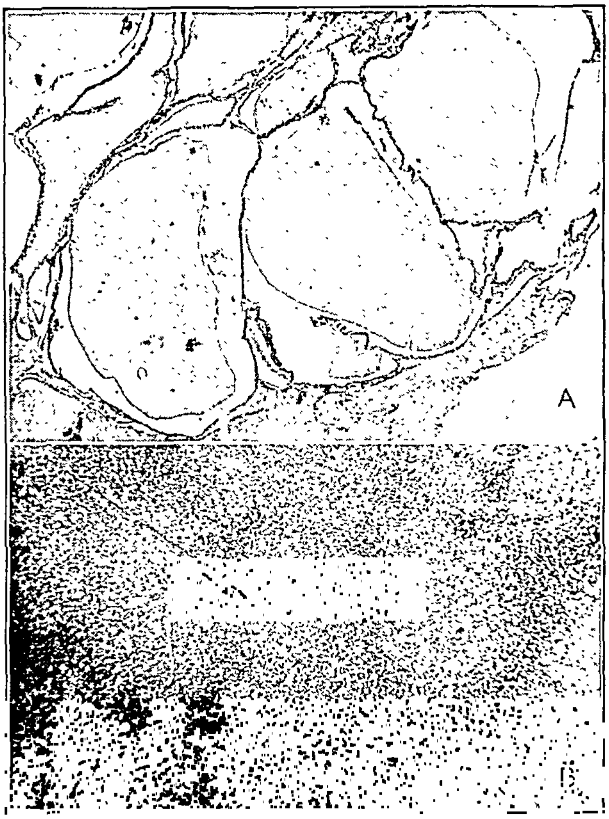

Fig. 2.—Photomicrograph (*A*) of hematoxylin and eosin-stained section and radioautograph (*B*) of tissue removed, magnification approximately × 20).

A tracer dose of 10 microcuries of radioactive iodine obtained from the Oak Ridge National Laboratory as $I^{131}$ in sodium bisulfite solution, $p_H$ 9.0, was given orally. A Geiger-Mueller tube 2.22 cm. (⅞ inch) long by 0.95 cm. (⅜ inch) in diameter, enclosed in a specially designed lead container to columnate the gamma rays given off by the radioactive iodine, was used to determine the localization of this material in the mass at the base of the tongue and in the zone in which the thyroid is normally located. The activity in the regions studied (expressed as counts per minute) was determined seven hours after oral administration of the tracer dose and is shown diagrammatically in figure 1.

On the basis of these results, it was concluded that the mass at the base of the tongue was functioning thyroid tissue and that the patient had little, if any, functioning thyroid tissue in the normal location.

The following morning a subtotal resection of the mass was performed by one of us (I. A. B.) using a suprahyoid approach.

The surgical specimen was fixed and embedded, and sections approximately 5 microns thick were mounted and covered with a thin film of celloidin. The sections were then taped to Kodak® pantomic X plates and left in place for five days. The resulting radioautograph when compared with the photomicrograph of a stained section from the same area (fig. 2), revealed that most of the radioactive iodine was localized in the acinar walls but that little was incorporated in the colloid.

[5] Buckman, L. T.: Lingual Thyroid, Laryngoscope **46**: 765, 888 and 936, 1936.

[6] Goetsch, E.: Lingual Goiter, Ann. Surg. **127**: 291, 1948.

The patient's postoperative course was uneventful, and she was discharged on the seventh postoperative day.

### SUMMARY

1. A case of lingual thyroid was proved by radioautograph and later by microscopic examination.
2. Radioactive iodine ($I^{131}$) was used as an aid in the preoperative localization of thyroid tissue.
3. The patient had a well developed lingual thyroid and no clinically demonstrable thyroid tissue in the normal position.

---

## TOXIC EFFECTS OF PERCUTANEOUSLY ABSORBED ESTROGENS

MAX A. GOLDZIEHER, M.D.
and
JOSEPH W. GOLDZIEHER, M.D.
New York

The fact that steroid hormones, particularly estrogens, can pass through the skin is well known, but the potential dangers of this route of absorption have not been noted previously. For this reason, we believe that the case reported here is of considerable theoretical as well as practical interest.

### REPORT OF A CASE

The patient, a 44 year old Scotsman, presented himself with the complaint of impotence of four months' duration. He had been married for twenty-three years and had fathered four children. His sexual activity had always been regular and satisfactory. Eighteen months before seeking medical advice he had started working as a chemist for a small pharmaceutic concern; his assignment was to extract and purify estrogenic substances from pregnancy urine. During this process his hands came in frequent contact with alcoholic solutions of high estrogenic potency, and he also admitted that occasionally he scraped freshly crystallized estrogenic materials from the filter paper with his fingers. About six months after this work was started, the patient noted tenderness and increased size of the breasts. Weight loss (about 10 pounds, or 5 Kg.), headaches and decreased libido developed in three months more, and there was also some decrease in the size of the penis. No change in the amount of facial or body hair was noted.

Physical examination disclosed definitely increased breast tissue of a lobular consistency; the areolas were unusually dark in comparison with the general complexion, and the nipples were also slightly pigmented, tender and decidedly erectile. The testes were smaller than normal and rather soft; the penis was also small. There were no other physical observations of note.

Laboratory studies disclosed nothing of significance except for the urinary estrogen secretion. This was determined by extraction according to the Bachman-Petit procedure[1] and fluorimetric measurement by the technic of Bates and Cohen.[2] A twenty-four hour specimen of urine was found to contain 185 plus or minus 20 gammas per twenty-four hours (normal 15 to 24 gammas per twenty-four hours).

The patient was advised to remove himself from all contact with estrogenic substances and, in addition, was given 75 mg. of testosterone propionate plus 60 mg. of pregnenolone acetate[3] per week intramuscularly for the next six weeks. One month after the patient had discontinued his work in the chemical plant, a repeat urinary estrogen determination showed an excretion of only 11 plus or minus 2 gammas per twenty-four hours. At the end of the course of therapy the headaches had disappeared, the breasts were far less tender and appeared smaller and the impotence showed improvement. There was not much change in the size of the genitalia.

### COMMENT

The clinical observations and the urinary estrogen determinations justify the conclusion that the large amounts of estrogen excreted by the patient were of exogenous origin and had entered the body by absorption through the unbroken skin. The fact that the urinary estrogen content was reduced to low normal values after the patient discontinued his occupational contact with estrogenic material corroborates this view. It seems reasonable to assume that the symptoms of genital atrophy, impotence and gynecomastia were due to the effects of exogenous estrogenic hormones.

Endogenous estrogen production could be ruled out. The two possible sources of such pathologic estrogen production are a Sertoli cell tumor of the testis and an adenoma of the adrenal cortex. Physical examination of the testes established the absence of the former; the latter could be excluded by the absence of other symptoms characteristic of cortical tumors, by the decreased estrogen excretion after contact with exogenous estrogen had ceased and by favorable response to treatment.

The percutaneous absorption of steroid hormones is a well established fact.[4] It has been shown, moreover, that the efficiency of absorption depends on the vehicle in which the steroid hormone is dissolved and brought in contact with the skin. The absorption of estrogen from a fatty medium (oil, ointment) has been estimated at 10 to 15 per cent; much better absorption is obtained from phenolic solutions, and almost 100 per cent is absorbed from alcoholic solution. An aqueous medium seems to be the most unfavorable. If results are measured by the antimasculine effects of estrogens on male rodents (atrophy and retraction of testes), the percutaneous absorption of estrogen from an organic solvent is as effective as, or even superior to, the same amount of estrogen administered subcutaneously.

According to Zondek[4] not more than 3 per cent of injected estrogen can be recovered from the urine within twenty-four hours. This has been confirmed by Jailer[5] and others.[6] On the basis of a 3 per cent recovery, and a physiologic estrogen elimination of 10 gammas, the surplus of 175 gammas represents the excretional equivalent of about 6 mg. of estrogen entering the body over a twenty-four hour period. In view of the high resorption from alcoholic solutions and the high concentrations of estrogen in the solutions handled by the patient, the absorption of this amount seems possible, although percutaneous absorption of such quantities and consequent feminization have never been reported previously, to our knowledge.

It is not likely that many persons will be exposed to an occupational hazard of such magnitude; however, this case serves to emphasize the fact that clinically significant amounts of steroid hormones can be unwittingly absorbed through the skin and that harmful effects may follow if this possibility is ignored or overlooked.

### SUMMARY

A case is reported of a 44 year old man, occupationally exposed to concentrated estrogenic solutions, who absorbed percutaneously an estimated equivalent of 6 mg. of estrogen per day, with consequent genital atrophy, impotence and gynecomastia.

# Council on Pharmacy and Chemistry

## REPORT OF THE COUNCIL

## PRESCRIPTION WRITING

*The Council has authorized publication of the following statements.* AUSTIN SMITH, M.D., *Secretary.*

### Harrison Narcotic Act and Prescriptions

The Harrison Narcotic Act is intended to control narcotic drugs so that they are used only for medical purposes. This law prohibits a pharmacist from filling an oral prescription; a written prescription must be received before the drug can be dispensed. A pharmacist can deliver narcotic drugs following a telephone order only when a genuine emergency exists. A physician cannot use his prescription form to obtain narcotic drugs for general office practice. Narcotic drugs for such use must be obtained on an official order from a qualified manufacturer or wholesale dealer. A prescription for a narcotic drug must be dated and signed on the date when issued, and it must bear the full name and address of the patient and the name, address and registry number of the practitioner. Such prescriptions must be typed or written in ink or indelible pencil. If typewritten the prescription must be signed by the practitioner. Prescriptions for narcotic drugs cannot be refilled. Narcotic prescriptions can be used only for legitimate medical purposes, responsibility for proper prescribing resting essentially with the practitioner. Narcotic prescriptions cannot be issued to addicts or habitual users of narcotics.

### Prescriptions Under the Federal Food, Drug and Cosmetic Act

In more recent years there have been developed laws that affect the prescribing and dispensing habits of physicians and pharmacists. In earlier years, with the exception of narcotics, the majority of drugs that were used by physicians were not subject to many restrictions, and it was customary to regard with considerable leniency oral prescriptions for drugs and refilling of written prescriptions without specific authorization. During the past few years state laws have been developed which prohibit the issuance of certain drugs without prescription. A local law exists in New York City. In addition, however, there is the Federal Food, Drug and Cosmetic Act, the provisions of which are not yet familiar to all members of the medical profession, but which, nevertheless, are intimately concerned with the use of drugs. Furthermore, new interpretations are being placed on these provisions, so that it is necessary for members of the medical profession to be fully aware of current restrictions on prescribing and dispensing habits if they wish to avoid or refrain from encouraging violations of this federal law.

While the Federal Food, Drug and Cosmetic Act has been regarded by many who are not familiar with its provisions as being concerned essentially with questions of accurate labeling, prevention of adulteration and safety, its provisions, on the basis of recent court decisions and interpretations of the Food and Drug Administration, go beyond such concepts. Among the restrictions placed on prescribing and dispensing habits are several concerned with so-called prescription items and refills. The physician must have a proper understanding of these restrictions if he is to prevent misunderstanding and perhaps even embarrassment for himself or for his patients and the pharmacists who fill his prescriptions. Under the act a prescription is generally regarded as a written order by the physician for a specific quantity of drug to meet a patient's specific needs. A prescription, then, cannot be refilled, according to current interpretation of the Federal Food, Drug and Cosmetic Act, without specific authorization of a physician. To refill the prescription without authorization is, in the eyes of the Administration, equivalent to an over-the-counter sale. Over-the-counter sale of drugs that are prescription items is prohibited by law, and pharmacists are not permitted to dispense prescription items without a prescription or to refill such prescriptions without specific authorization. This means that the physician must authorize as many refills as he believes are necessary for the patient for whom the prescription is intended at the time he writes the prescription. If such authorization is missing from the original prescription the pharmacist, according to the administration, must assume that the physician intended the prescription be filled only once. The physician, of course, can issue instructions later for refills if such action seems indicated. These later instructions to the pharmacist may be verbal or written, but they must be issued directly to the pharmacist and not indirectly through the patient.

Prescription drugs are those which carry on the label a statement such as "Caution: To be dispensed only by or on the prescription of a physician" (or dentist or veterinarian). If such a legend is not present on the label, then the item presumably is a so-called non-Rx legend drug, in which case the labeling must bear adequate directions for use—which means for self medication. If a drug bears an Rx legend it cannot be sold without a prescription.

At times pharmacists must place on a prescription label certain warnings; for example, "Warning: May be habit forming." This is done if the drug is a narcotic or hypnotic substance named in a certain section of the Federal Food, Drug and Cosmetic Act if (*a*) the doctor does not mark the prescription order as not refillable or (*b*) refilling is not prohibited by local law. If the physician specifies in the prescription order that it may be refilled a certain number of times at stated intervals, and that it is not refillable after the last filling, none of the dispensed material is required to bear the warning label.

Another warning that occasionally must be placed on the prescription label by the pharmacist is one associated with certain potent drugs. So far, the Food and Drug Administration has decided that thiouracil, prophylthiouracil and pentaquine must bear a warning because of the possibility of untoward reactions from the use of these drugs. This warning reads: "Warning: This drug may cause unfavorable reactions in some individuals. Your physician has explained or will explain to you the symptoms that must be watched for and precautions that must be taken to guard against ill effects. Do not take in larger doses, or for a longer time than specifically directed by the physician."

Physicians who dispense as a bona fide part of their professional practice and who by oral statements impress on the patient adequate directions for use and warnings about probable unfavorable reactions are not subject to the labeling requirements of the law that apply to pharmacists in filling prescriptions. Nevertheless, it would be in the interest of safety for such a physician to supplement his oral directions and warnings with label notations on the dispensed package.

Physicians whose dispensing is not a bona fide part of their professional practice are, of course, subject to the same requirements that apply to pharmacists.

The Food and Drug Administration does not issue an official list of drugs which may be sold only on prescriptions. However, any item that bears the prescription legend is limited to issuance by prescription, and a prescription for such an item must be written, as oral prescriptions can be recognized by a pharmacist only in times of emergency.

SATURDAY, AUGUST 6, 1949

## COMMITTEE OF THE NATIONAL ACADEMY OF SCIENCES ON THE INVESTIGATION OF CORTISONE

The recent report by Hench, Kendall, Slocumb, and Polley of the dramatic effectiveness of the adrenal cortical steroid, Cortisone (first isolated by E. C. Kendall), in the treatment of rheumatoid arthritis developed the difficult problem of distributing the limited amount of the substance obtainable for the rest of 1949. Originally obtained from the cortex of the adrenal gland, *Cortisone is now being prepared from a bile acid.* While the value of Cortisone in controlling the symptoms of rheumatoid arthritis is regarded as established, much remains to be learned concerning its possible untoward effects, its usefulness in other diseases and the mechanism of its action. The small amount which can be made during the last five months of 1949 will be used only for clinical and experimental research and will be made available to those investigators who may best provide the information needed to insure its safe and effective use.

The Research Corporation, a nonprofit organization which administers patents in the interest of public welfare and for the furtherance of scientific research, has aided in the development of the processes for making Cortisone. The corporation will continue to further the development of these processes and to stimulate research on the mechanisms of action of the substance. In fulfilling these functions, the Research Corporation requested the President of the National Academy of Sciences to appoint a Committee on Investigation of Cortisone, with assurance that its recommendations will be accepted as final with respect to the available supply during 1949.

The membership of the committee, appointed with the sanction of the council of the academy, includes Chester S. Keefer, chairman, Hans T. Clarke, E. A. Doisy, Robert F. Loeb, C. N. H. Long, E. K. Marshall Jr. and Joseph T. Wearn. David E. Price has been appointed to act as liaison between the committee and the U. S. Public Health Service.

The committee is planning arrangements designed to utilize to the fullest possible extent the resources of the National Research Council and the information and advice of experienced and competent investigators in the United States and Canada. Not only will rheumatism and other diseases for which relief may be anticipated continue to be investigated, but also aspects of physiology and pharmacology which are basic to fuller understanding of Cortisone.

While the academy does not have funds with which to buy Cortisone or to support investigations, the needed funds will no doubt become available from both public and private sources. The committee has accepted this responsibility because of the conviction that a new discovery of the greatest importance to the health and welfare of countless persons has been made and that it is vital to promote its most rapid and intelligent development.

Applications for a supply of Cortisone must be submitted on a form that can be obtained from the chairman of the committee, Dr. Chester S. Keefer, 2101 Constitution Avenue, Washington 25, D. C. Consideration will be given only to requests from institutions where adequate facilities for investigation and clinical control are available.

## INACTIVATION OF HEPATITIS VIRUS WITH ULTRAVIOLET RAYS

Jaundice after the administration of human blood products is now a well recognized possibility. The jaundice is readily distinguishable from hemolytic icterus, which may develop promptly after transfusion with incompatible blood. Clinically the condition resembles epidemic hepatitis. The incubation period is unusually long, two to three months, in contrast with the twenty to forty day period believed to occur in epidemic hepatitis.

The quantity of icterogenic agent involved in transmission of the infection may be extremely small, as demonstrated by Bradley and his co-workers,[1] who produced jaundice in human volunteers by the administration of as little as 0.1 cc. of homologous serum. MacCallum and Bauer, Sheehan, and Droller[2] have incriminated the syringe and the needle used either for injection or for taking blood as capable of harboring and transmitting the infective agent. Mendelssohn and Witts demonstrated that some of the blood is sucked back into the vein when blood is taken from a vein with a syringe; this occurs when the tourniquet is released. If the syringe is not sterile, the patient is exposed to infection. MacCallum and Bauer[3] showed that the icterogenic agent survived heating at 56 C. for one hour, and Oliphant found that the jaundice-producing agent is filtrable, survives drying in vacuum, storage for long periods in serum at 4 C. and heating to 56 C. for one-half hour in the dried state.

---

[1] Bradley, W. H.; Loutit, J. F., and Maunsell, K.: An Episode of "Homologous Serum Jaundice," Brit. M. J. **2:** 268-269 (Aug. 26) 1944.

[2] Cited in Syringe Transmitted Hepatitis, editorial, J. A. M. A. **129:** 278-279 (Sept. 22) 1945.

Effective sterilization of syringes and needles involves thorough cleansing followed by sterilization in the hot air oven (160 C. for one hour) or in the autoclave or by boiling for not less than fifteen minutes. Malmros and his co-workers[4] stated the belief that the risk of infection can be eliminated by the use of sterile needles alone without syringes at venepuncture and by the provision of a sufficient number of syringes to permit a fresh sterilized instrument's being used for each patient.

The suggestion that a connection between the needle and the syringe could be used to prevent the contamination of the syringe nozzle in mass inoculations is deprecated by Janeway, who does not believe that there is any adequate substitute for the use of an individual syringe and needle for each patient.

Oliphant[5] demonstrated in inoculation experiments on human beings that irradiation of icterogenic serum with ultraviolet rays inactivated the infective agent. This suggested the possibility that ultraviolet irradiation might be useful in processing potentially icterogenic blood and blood products. A new method of rapidly sterilizing suspensions of bacteria and viruses has been developed by Oppenheimer and Levinson. The method consists of exposing rapidly flowing thin films of liquid for fractions of a second to a new and powerful source of ultraviolet rays emitting intense radiation of 2,537 angstrom and 1,849 angstrom wavelengths. Stokes[6] and his co-workers, utilizing a Habel-Sockrider type of apparatus for irradiating the icterogenic serum, inoculated 11 volunteers with irradiated icterogenic serum. None showed any evidence of hepatitis. Studies of the irradiated plasma did not indicate any alteration of the electrophoretic pattern. By chemical fractionation methods, the plasma proteins remained essentially normal. Of the 15 volunteers who received nonirradiated icterogenic serum, 3 showed hepatitis with jaundice, 1 hepatitis without jaundice and 3 presumptive hepatitis. This experiment supports the work of Oliphant and strongly favors the routine use of exposure to ultraviolet rays of serum and plasma under properly controlled conditions.

## INSULIN ECONOMY

In anticipation of a predicted shortage of insulin in the near future, Johlin[1] of the Department of Biochemistry, Vanderbilt University, has suggested a plausible method for economy in the use of insulin. Experiments on rabbits indicate that the conventional dosage of insulin can be reduced by half through the use of certain amino acid adjuvants.

Earlier investigators[2] found that the normal blood sugar level of rabbits can be increased or decreased by administrations of adequate doses of amino acids. Schenk[3] found that glycine was the most effective of the amino acids which decreased the blood sugar level. Given orally 1.5 Gm. glycine, produced hypoglycemia, which reached its maximum in about one hour and disappeared within eight hours. Schenk found that self-administered glycine produced similar hypoglycemia in man.

As a preliminary to tests of the adjuvant action of glycine in insulin therapy, Johlin determined the minimum convulsive dose of insulin for adult rabbits. This varied from 0.6 to 0.7 unit per kilogram of body weight for different rabbits. Injection of half of the convulsive dose caused the blood sugar level of rabbits to fall from 90 mg. to 50 mg. per hundred cubic centimeters by the end of one hour, with full recovery by the end of five hours. Simultaneous injection of 3 mg. glycine per kilogram of body weight did not cause appreciable change in the severity or duration of this half-convulsive hypoglycemia. When the same rabbits were retested some weeks later, however, the animals reached the convulsive state with the half-convulsive dose. There was thus a twofold increase in insulin reaction due to previous glycine injection.

This heightened insulin reaction was confirmed in rabbits repeatedly given injections with glycine alone. Tested two weeks to three months later, the animals reacted to the half-convulsive dose with hypoglycemia approaching the convulsive level. The blood sugar fell to 40 mg. per hundred cubic centimeters after one hour and only partially recovered to the 60 mg. level after five hours.

Johlin concludes from such data that repeated injections of glycine in rabbits increase the subsequent therapeutic effect of insulin for prolonged periods. Johlin has not offered a theoretical explanation for this insulin hypersensitivity. If similar prolonged booster effects can be demonstrated in man, a practical method of insulin economy will have been found.

# Current Comment

## TOXIC EYE HAZARDS

"Accident Facts," published by the National Safety Council, reports that approximately 75,000 occupational eye injuries occur each year; of these, 5,000 are permanent. Increased industrialization has resulted in a corresponding rise in injuries of the eyes. The Joint Committee on Industrial Ophthalmology established by the Council on Industrial Health of the American Medical Association prepared a "Manual on Toxic Eye Hazard,"[1] useful for both professional and lay personnel. In chapter 1, Dr. Ralph S. McLaughlin of Charleston, W. Va., and Thomas A. Walsh of the American Optical Company discuss the various standards and tests for eye protection equipment and a well organized eye protection program. A complete description and discussion of standards and tests of equipment for protection of the eyes was prepared for the Joint Committee by J. M. McGreevy and L. Banet from their experiences in naval shipyards. Chapter 2, prepared by Prudence Van Arsdell, presents detailed tables of individual chemicals, organic and inorganic, giving the name, trade name and main effects of these chemicals on the eye. Chapter 3 discusses first aid and emergency treatment of chemical eye injuries. A rather extensive bibliography on medical and surgical treatment of injuries of the eye is appended. The research behind this project has taken two years, and a prodigious amount of work has been done by the authors. The Committee feels that the manual should be in the hands of every ophthalmologist, medical director, industrial nurse, safety director and public health officer and all others interested in eye conservation.[1]

## ELECTROSHOCK IN PSYCHOSES

At the time of the Annual Session of the American Psychiatric Association, an official statement on the use of electroshock was issued by the president, Dr. William C. Menninger, and by Dr. Nathan K. Rickles, president of the Electroshock Research Association. The statement follows:

> Electroshock therapy is accepted today as the most effective physical agent in the successful treatment of the majority of the affective psychoses when given by properly qualified psychiatrists.
>
> It should be stressed that at no time is electroshock advanced as a cure-all, but only as one very effective agent in selected classes of mental illness. It should always be preceded by a complete and thorough psychiatric study of the patient which includes an evaluation of his mental and physical status, his family and his environment, and also be followed with adequate psychosocial study and psychotherapeutic guidance.

This decision should be known particularly to general practitioners, since at least two thirds of acute psychoses are first seen by general practitioners.

## GLUTAMINASE

Current research is turning with increasing emphasis to a consideration of the chemical reactions of the individual cell. These reactions are under the control of enzymes, and in the living cell they are regulated by those factors which control the activity of the enzymes; in death, regulatory forces are largely removed and the chemical reactions proceed uninhibited to their equilibrium states. The factors which control the activity of one of these enzymes, renal glutaminase, have been studied extensively by a number of workers.[1] This enzyme acts on glutamine, a constituent of normal blood, to supply ammonia which is used in excretion of acids as their ammonium salts and the maintenance of the normal acid-base balance. When kidney tissue slices are incubated with glutamine, the formation of ammonia is increased by the presence of the sodium salts of pyruvic, phosphoric and beta-hydroxybutyric acids. The control of the activity of glutaminase in the living animal thus appears to be under the automatic control of those substances which require the formation of urinary ammonia. Beta-hydroxybutyric acid, the substance which is in large part responsible for the development of acidosis of pathologic states, is the most effective of the substances studied for the stimulation of ammonia formation.

## AVAILABILITY OF VITAMIN A

In securing data on the requirement for a dietary essential, some reliable criterion of adequacy is used; also necessary is knowledge of the amount of the substance under investigation which is consumed. In making such a study of the human requirement for vitamin A, Callison and Orent-Keiles[1] estimated the intake of vitamin A activity from raw, quick-frozen and pressure-cooked carrots, using both the biologic assay with rats and a chemical method whereby the carotene was extracted and measured. The experimental animals utilized the carotene from carrots only about one third as well as they did that from peas, spinach or an oil solution of carotene. The resulting bio-assay on carrots gave values far smaller than those secured by the chemical method. Recently, the government investigators[2] studied the availability of carotene (vitamin A activity) from carrots and from sweet potatoes as indicated by the comparison of the results of bio-assay with those from chemical determination. Evidently the laboratory rat does not utilize all of the carotene contained in these vegetables; only 34 per cent was obtained from sliced carrot, 41 per cent from carrot purée and 37 per cent from sweet potato. Naturally, the question of availability of nutrients in plant tissues in human nutrition is raised by the foregoing observations. It would appear advisable to revise the tables of food composition which are widely used by dietitians so that the factor of biologic availability is included in the calculations of requirements. The possible disparity between the quantity of nutrients eaten and the amount absorbed cannot be ignored.

# ORGANIZATION SECTION

## Washington Letter

*(From a Special Correspondent)*

Aug. 1, 1949.

### Dr. Hench Heads Federal Panel on Arthritis

Establishment of a new study section on arthritis and rheumatic diseases, headed by Dr. Phillip Hench of Mayo Clinic, is part of the current reorganization of advisory panels serving National Institutes of Health. Appointment of Dr. Hench as chairman was announced July 31 by Federal Security Administrator Oscar R. Ewing. Nine other investigators have accepted appointment to the new section. They are Drs. Walter Bauer, Boston; Granville Bennett, Chicago; Jerome W. Conn, Ann Arbor, Mich.; W. Paul Holbrook, Tucson, Ariz.; Robert Loeb, New York City; Fred Moore, Los Angeles; Jane A. Russell, New Haven, Conn.; Emil L. Smith, Salt Lake City, and Alfred L. Wilds, Madison, Wis.

### School Health Services Bill Is Modified

The House subcommittee on health legislation approved the school health services bill (S. 1411) in revised form and submitted it to the House Interstate and Foreign Commerce Committee late in July. The subcommittee did not change the portion of the bill which permits states to provide for treatment of children without regard to their families' economic status. Heeding arguments made by the American Optometric Association, the legislators have amended the bill to include optometry among the health services recognized. Other changes deal with provisions affecting pupils of parochial schools.

### Quarterly Lobbying Reports Made Public

The Committee for the Nation's Health, whose efforts are devoted chiefly to stimulating public sentiment for compulsory health insurance, has informed the Clerk of the House that its income for the second quarter of 1949 was $5,080.95. The sole contributor of $500 or more was Mrs. W. H. Durham, Berkeley, Calif., according to the committee's quarterly lobbying report. An amended report for the first quarter showed contributions in excess of $40,000. Principal donors were Lessing Rosenwald, Mrs. Marion R. Ascoli, Mrs. Adele Levy, Mrs. Edith R. Stern and William Rosenwald, who gave $6,666.67 each, and Mr. and Mrs. Albert D. Lasker, $5,555.56. Expenditures for the first half of the year totaled $55,911.90.

The American Medical Association filed a report showing that the assessment fund was increased by $832,377.20 between April 8 and June 30. This brought the total to date to $1,984,010.90. Expenses of the educational campaign conducted by Whitaker and Baxter totaled $350,109.66 in the second quarter.

The Indiana State Medical Association, in its report, listed contributions by Eli Lilly & Company ($10,000), Mead Johnson & Company ($5,000) and the Indianapolis Medical Society ($2,000).

The American Osteopathic Association, National Chiropractic Insurance Co., American Hospital Association, American Dental Association and American Parents Committee were among other organizations filing quarterly reports.

### USPHS Appoints Its First Pharmacist Director

Raymond Kinsey, a career man in Public Health Service since 1914 and a member of its commissioned corps since 1930, has been promoted to the rank of pharmacist director. He is the first pharmacist officer to achieve director grade.

### Senator Taft Among Critics of Department of Welfare

The Senate Committee on Expenditures, which is taking testimony on the Truman plan to transform the Federal Security Agency into a Department of Welfare, heard strenuous objections on July 28 from Senator Robert A. Taft of Ohio. He stated, in substance, that Public Health Service (formerly in the Treasury Department) already has lost much of its authority under FSA Administrator Ewing and the trend in that direction would be accelerated if it became part of a Department of Welfare.

Among witnesses scheduled to be heard before the hearings close are Dr. Frank Borzell, for the American Medical Association, and Robert P. Fischelis, representing the American Pharmaceutical Association.

Previously the Senate Committee on Expenditures heard dissenting testimony by Dr. James Raglan Miller, American Medical Association; Dr. Robert E. S. Young, Association of American Physicians and Surgeons; Dr. J. J. Montfort, Arkansas Medical Society, and Dr. F. Harold Gale, American Dental Association. They pointed out that the best solution would be establishment of a Department of Health and expressed doubt that subordination of government health activities to a layman Secretary of Welfare would be in the best interests of the people.

### $3,044,140 in Mental Health Grants Awarded

FSA Administrator Ewing on July 28 announced $489,584 in federal grants to continue financing of 35 research projects in the neuropsychiatric field and $2,554,556 for subsidization of training in psychiatry, neurology, clinical psychology, psychiatric nursing and psychiatric social work. The awards had been recommended by the National Advisory Mental Health Council and approved by Dr. Leonard A. Scheele, Surgeon General. Additional grants for new projects will be announced in the near future. The training grants include stipends for 456 graduate students.

### Bureau of Internal Revenue Disclaims "Crackdown" on Doctors

No political significance should be attached to the fact that tax liens have been filed against a number of physicians in various parts of the country and that some others face criminal action on evasion charges, according to an official spokesman for the Bureau of Internal Revenue. Taking cognizance of charges that a campaign is on to intimidate the medical profession against opposing the Administration program for compulsory health insurance, the Revenue Bureau official said that such allegations are wholly without foundation. Since the end of the war, he explained, a larger percentage of income tax returns filed by doctors have been subjected to "verification," and the result has been the discovery of a great number of cases in which insufficient taxes were paid. Substantiating his argument that the government is conducting no special tax drive against physicians or members of any other profession and that politics is not involved, the official pointed out that prominent members of the Democratic party have been among the defendants in some of the most noteworthy tax law violation cases of the last few years.

---

## PUBLIC RELATIONS CONFERENCE

The second annual medical public relations conference has been scheduled for November 5-6 in Chicago, immediately following the Secretaries and Editors Conference on November 3-4. The meeting this year will be built around the state medical society public relations chairman—providing him ample opportunity to exchange ideas and to present and receive information pertinent to his activities and responsibilities.

As a result of the success of the one day medical public relations conference in St. Louis last November, this year's meeting has been expanded to a day and a half, opening the morning of Saturday, November 5, and closing with a luncheon on Sunday, November 6.

Invited are public relations committee chairmen, executive secretaries and public relations directors of state medical societies and of county medical societies which maintain executive offices. Some state presidents and other public relations staff members will undoubtedly attend as they did in St. Louis. Conference arrangements are being handled by the A. M. A. Public Relations Department headed by Lawrence Rember.

## DOCTORS DEPART ON ALASKAN MEDICAL MISSION

Under sponsorship of the United States Department of Interior and the American Medical Association, five physicians left July 16 for Anchorage, Alaska, for a two week session of conferences and clinics. This was the third time in five years that medical teams have visited Alaska under Department of Interior–A. M. A. sponsorship.

The conference will be conducted by five specialists to provide Interior Department medical officers now serving in remote areas in Alaska with an intensive series of seminars, demonstrations, clinics and consultations based on late technics and developments in the fields of internal medicine, general surgery, obstetrics and gynecology, tuberculosis and ophthalmology.

At the same time eight other physicians volunteered to go to Alaska to replace the Interior Department doctors, so that they could leave their outlying posts to attend the seminar.

The mission, which departed from Washington in a transport plane provided by the U. S. Air Force, included Drs. Elliott B. Hay, Houston, Texas; Edward N. Smith, Oklahoma City; Albert N. LeMoine Jr., Kansas City, Mo.; Harry Julius Isaacs, Chicago, and George C. Turner, Chicago.

# Medical Legislation

## STATE LEGISLATION

### California

**Bills Enacted.**—H. Res. 239 was adopted June 27, 1949. It provides for the creation of an interim committee to study and analyze, among other things, voluntary plans for **hospital and/or health insurance** or plans operating to protect persons from the high costs of sickness and accident in this state. H. Res. 292 was adopted July 1, 1949. It provides for the creation of an interim committee to study, among other things, the feasibility of establishing and maintaining institutions for the treatment, custody and care of **alcoholics and chronic inebriates.** A. 252 has become chapter 765 of the Laws of 1949. It makes it a misdemeanor for any person to perform an **autopsy on a dead body** without having first obtained the written authorization of the coroner or other authorized public officer or the person who has the right of disposition of the body. A. 1010 has become chapter 756 of the Laws of 1949. It provides that any person licensed to practice medicine in another state who complies with the requirements of the California Medical Practice Act with respect to registration with the board and graduation from a school approved by the board may be **appointed to a medical staff** within a state institution under the Department of Corrections and under supervision of a licensed physician and surgeon may treat persons under the jurisdiction of such state institution for a period not to exceed one year. Qualified physicians and surgeons for such purpose cannot be recruited in the state of California. At the end of the year the physician and surgeon must have secured a physician's and surgeon's certificate in order to continue as a member of the medical staff. Until such person has obtained a physician's and surgeon's certificate he shall not engage in the practice of medicine and surgery in the state except to the extent provided for in this law. A. 1948 has become chapter 794 of the Laws of 1949. It amends the business and professions code by providing that a physician who served in any of the armed forces of the United States and is included within the definition of the term "veteran" should have the same rights and privileges under the medical practice act as **medical officers in the United States Army, Navy or Public Health Service.**

### Oklahoma

**Bills Enacted.**—H. 54 was approved May 31, 1949. It amends the hospital licensing law by exempting therefrom any place maintained primarily for the purpose of providing a home or place to live for **indigent aged persons.** H. 162 was approved June 6, 1949. It prohibits the delivery of **barbiturates** except by a pharmacist on an original prescription from a person licensed by law to prescribe and administer barbiturates. The delivery of barbiturates by a physician in the course of his practice is exempted from the provisions of this law. H. 178 was approved May 23, 1949. It provides regulations for the incorporation and licensing of **charitable and benevolent nonprofit hospital service** and indemnity corporations and nonprofit medical service and indemnity corporations. H. 179 was approved June 9, 1949. It amends the medical practice act by authorizing the board of medical examiners to require all applicants for licensure to present a properly verified certificate that they have served a **one year's internship** in a general **hospital** approved and recognized by the board. H. 180 was approved May 31, 1949. It supplements the basic science act by authorizing the issuance of a certificate of ability in the basic sciences to **physicians, chiropractors and osteopaths** who were licensed in the state of Oklahoma at the time the basic science act was passed in 1937 either on the basis of examination or reciprocity. H. 206 was approved June 6, 1949. It makes it unlawful for any organization to require an **applicant for employment,** as a condition of employment, to submit to or take a physical or medical examination without providing such examination at no cost to the applicant. H. 311 was approved May 31, 1949. It authorizes the Oklahoma **Spastic Paralysis Commission** to establish and maintain the Oklahoma Cerebral Palsy Institute and to furnish care, maintenance, training, treatment equipment, education and rehabilitation to persons afflicted with spastic paralysis within said institute. H. 437 was approved June 6, 1949. It is a **mental health law.** S. 171 was approved May 16, 1949. It amends the law relating to **narcotic drugs** by including isonipecaine, amidone, isoamidone and keto-bemidone within the definition of the term "narcotic drugs." S. 172 was approved May 16, 1949. It authorizes the board of nurse examiners to issue licenses to qualified persons desiring to practice as a **"Licensed Nursing Attendant,"** which is defined to mean a person licensed as such by the Board of Nurse Examiners to perform such duties as are required in the physical care of patients but not having the technical understanding necessary for and required of professional nurses. S. 253 was approved June 2, 1949. It amends the medical practice act by authorizing the **board of medical examiners** to issue a temporary license to any applicant eligible for permanent license who desires a license only for the purpose of serving a residency in the state in hospitals approved for resident training or the board. Such licenses would expire at the end of one calendar year or at the expiration of the resident training but they may be renewed annually for not to exceed two additional years on approval of the board. S. 301 was approved June 2, 1949. It authorizes the state department of public health to create and maintain a **cancer control division** to promote a program for the prevention of cancer.

### Wisconsin

**Bill Introduced.**—A. 743, to amend the law relating to the **use of cats or dogs** for experimental purposes, proposes to make it unlawful for any person to take or send outside the state or to purchase or otherwise acquire in this state for the purpose of taking or sending outside the state any living cat or dog to be used for any medical, surgical or chemical investigation, experiment or demonstration.

**Bills Enacted.**—A. 11 has become chapter 402 of the Laws of 1949. It provides for the creation of a **director of nursing education** and also provides regulations for the licensing of practical nurses. A. 438 has become chapter 438 of the Laws of 1949. It amends the **chiropractic practice act** by setting forth the grounds for the revocation or suspension of a license to practice chiropractic. A. 472 has become chapter 297 of the Laws of 1949. It eliminates from the annual registration requirements of **chiropractors** the former provision that at the time of such renewal the applicant must present satisfactory evidence that he has attended at least one of the two day educational programs conducted by the Wisconsin Chiropractic Association. A. 475 has become chapter 457 of the Laws of 1949. It provides that consent for a licensed physician to conduct a **postmortem examination** of the body of a deceased person shall be deemed sufficient when given by whichever one of the following assumes custody of the body for purposes of burial: father, mother, husband, wife, child, guardian, next of kin or, in the absence of any of the foregoing, a friend or a person charged by law with the responsibility for burial. A. 642 has become chapter 431 of the Laws of 1949. It provides that **osteopathic and medical applicants** shall be given the same examination in all subjects and shall be given the same license.

# Coming Medical Meetings

Aero Medical Association, New York, Aug. 29-Sept. 2. Dr. Thomas H. Sutherland, 214 S. State St., Marion, Ohio, Secretary.

American Association of Obstetricians, Gynecologists and Abdominal Surgeons, Hot Springs, Va., The Homestead, Sept. 8-10. Dr. Leroy A. Calkins, University of Kansas Medical Center, Kansas City 3, Kan., Secretary.

American Congress of Physical Medicine, Cincinnati, Netherlands Plaza Hotel, Sept. 6-10. Dr. Richard Kovacs, 2 E. 88th St., New York 28, Secretary.

American Hospital Association, Cleveland, Sept. 26-29. Mr. George P. Bugbee, 18 East Division St., Chicago, Executive Secretary.

American Roentgen Ray Society, Cincinnati, Oct. 4-7. Dr. H. Dabney Kerr, University Hospitals, Iowa City, Iowa, Secretary.

Colorado State Medical Society, Denver, Shirley-Savoy Hotel, Sept. 20-23. Mr. Harvey T. Sethman, 835 Republic Bldg., Denver, Executive Secretary.

Indiana State Medical Association, French Lick, Sept. 25-27. Mr. Ray E. Smith, 1021 Hume-Mansur Bldg., Indianapolis 4, Executive Secretary.

International Congress of Biochemistry, Cambridge, England, Aug. 19-25. Lieut. Col. Francis J. Griffin, 56 Victoria St., London, W.C.1, Organizer.

International Neurological Congress, Paris, France, Sept. 5-10. Dr. Raymond Garcin, 19 rue de Borgogne, Paris, General Secretary.

Michigan State Medical Society, Grand Rapids, Pantlind Hotel and Civic Auditorium, Sept. 21-23. Dr. L. Fernald Foster, 2020 Olds Tower, Lansing 8, Secretary.

National Medical Association, Detroit, August 8-12. Dr. John T. Givens, 1108 Church St., Norfolk, Va., Secretary.

Nevada State Medical Association, Elko, Sept. 29-Oct. 1. Dr. Roland W. Stahr, 118 California Ave., Reno, Secretary.

Pennsylvania, Medical Society of the State of, Pittsburgh, Hotel William Penn, Sept. 26-29. Dr. W. F. Donaldson, 8104 Jenkins Arcade, Pittsburgh 22, Secretary.

Utah State Medical Association, Salt Lake City, Sept. 1-3. Dr. Ray T. Woolsey, 42 S. Fifth East St., Salt Lake City 2, Secretary.

Vermont State Medical Society, Burlington, Sept. 8-9. Dr. James P. Hammond, 542 Main St., Bennington, Secretary.

Washington State Medical Association, Seattle, Olympic Hotel, Sept. 11-14. Dr. James W. Haviland, 338 White-Henry-Stuart Bldg., Seattle, Secretary.

Wyoming State Medical Society, Casper, Sept. 12-14. Dr. George H. Phelps, 1606 Capitol Avenue, Cheyenne, Secretary.

# GOVERNMENT SERVICES

## ARMY

### OFFICERS ACCEPTED FOR ADVANCED TRAINING

The following Medical Department officers have been accepted for advanced training at the civilian institutions indicated: Colonels Berna T. Bowers, Ophthalmological Study Council, Boston; Albert H. Robinson, University of Pennsylvania, Philadelphia; Lieut. Colonels William B. Draper, University of Pennsylvania, Philadelphia; Raymond M. Williams, University of Pennsylvania, Philadelphia; Orland S. Olsen, University of Cincinnati, Ohio; Merle E. Smith, Harvard University School of Public Health, Boston; Majors Kenneth E. Hudson, University of Pennsylvania, Philadelphia; Donald S. Myers, Harvard University, Boston; Robert S. Lockwood, University of Nebraska, Omaha; Theodore S. Malinowski, University of Indiana, Indianapolis; William A. Collins Jr., Ohio State University, Columbus, Ohio, and Captain James G. Wood Jr., Massachusetts General Hospital, Boston. Colonels Lawrence A. Matternes, University of Pennsylvania, Philadelphia, general surgery; Tom Whayne, Harvard University, Boston, public health; James O. Gillespie, University of California, San Francisco, endocrinology; Lieut. Colonels Fratis L. Duff, Johns Hopkins University, School of Hygiene and Public Health, Baltimore, public health; Stuart I. Draper, University of California, School of Public Health, Berkeley, public health; Majors Phillip M. Nabbe, Minnesota Department of Health, St. Paul, public health, and Albert Dresner, Cook County Graduate School of Medicine, Chicago, allergy.

### AMERICAN REGISTRY OF PATHOLOGY

The American Registry of Pathology is one of the four major departments of the Army Institute of Pathology. The first registry in the group which now comprises the American Registry of Pathology was established in the Army Medical Museum by the Academy of Ophthalmology and Otolaryngology in 1922. Over the years, this registry has accumulated more than 26,000 ophthalmologic specimens and has been the basis of many important researches in ophthalmic pathology. As additional registries were organized they were grouped in an overhead organization known as the American Registry of Pathology under the auspices of the National Research Council. Under the direction of Colonel James E. Ash, the activities of the American Registry of Pathology were greatly expanded. There are now 19 individual registries, which in the aggregate cover practically all of the specialty fields in medicine and contain nearly 75,000 cases.

### EDUCATIONAL TRAINING

The following medical officers have been accepted for advanced training in civilian institutions:

| | | |
|---|---|---|
| Clifford A. Gray, Col. | Mayo Clinic, Rochester, Minn. | Radiology |
| Carlton W. Sargent, Lieut. Col. | University of Georgia, Augusta, Ga. | Obstetrics and gynecology |
| Augustus A. Hall, Lieut. Col. | Bellevue Hospital, New York | Internal medicine |
| Harold W. Glascock Jr., Lieut. Col. | Columbia University, New York | Curriculum development and adult education |
| Urban L. Throm II, Major | Cornell University Medical College, New York | Dermatology and syphilology |
| John W. White, Capt. | Gallinger Municipal Hospital, Washington, D. C. | Surgery |
| William A. Graber, First Lieut. | Cook County Hospital, Chicago | Obstetrics and gynecology |

### CERTIFIED BY SPECIALTY BOARDS

The following Regular Army Medical Corps officers have recently been certified by the American Specialty Boards indicated:

| | |
|---|---|
| Lieut. Col. Bruno Jastremski | Internal Medicine |
| Lieut. Col. Benjamin H. Sullivan Jr | Internal Medicine |
| Major Robert B. Dickerson | Internal Medicine |
| Major Aaron L. Kaminsky | Internal Medicine |
| Col. Francis W. Pruitt | Internal Medicine |
| Lieut. Col. Wayne G. Branstadt | Preventive Medicine and Public Health |
| Lieut. Col. Edward J. Dehne | Preventive Medicine and Public Health |
| Major Claude M. Eberhart | Preventive Medicine and Public Health |
| Lieut. Col. Thomas G. Faison | Preventive Medicine and Public Health |
| Lieut. Col. B. Dixon Holland | Preventive Medicine and Public Health |
| Major Gen. Edgar E. Hume | Preventive Medicine and Public Health |
| Lieut. Col. Gottlieb L. Orth | Preventive Medicine and Public Health |
| Col. Tom F. Whayne | Preventive Medicine and Public Health |
| Col. William L. Wilson | Preventive Medicine and Public Health |
| Col. Wesley C. Cox | Preventive Medicine and Public Health |
| Col. Rufus L. Holt | Preventive Medicine and Public Health |
| Col. Don Longfellow | Preventive Medicine and Public Health |
| Col. Karl R. Lundeberg | Preventive Medicine and Public Health |
| Col. Thomas E. Patton | Preventive Medicine and Public Health |
| Lieut. Col. Dell F. Dullum | Radiology |
| Major Harold F. Bertram | General Surgery |
| Major Roy C. Rounds | Orthopedic Surgery |
| Col. Conn L. Milburn | Pediatrics |
| Lieut. Col. Louis S. Leland | Dermatology and Syphilology |
| Major Abram A. Bennesson | Clinical Pathology |
| Major Gilbert B. Stansell | Anatomic Pathology |
| Col. James H. Forsee | Thoracic Surgery |
| Lieut. Col. John H. King Jr | Ophthalmology |
| Lieut. Col. Edward A. Zimmermann | Gynecology and Obstetrics |
| Major Humbert L. Riva | Obstetrics and Gynecology |

## NAVY

### POSTGRADUATE INSTRUCTION

The following Regular Navy Medical Officers have been nominated for postgraduate instruction under the graduate medical training program in the institutions indicated: Commanders Sidney A. Britten of Syracuse, N. Y., to instruction in public health at Harvard School of Public Health, Boston; Leonard J. Hahne of Savannah, Ga., to a fellowship in ophthalmology at the Illinois Eye and Ear Infirmary, Chicago; William S. Wray of Northfork, W. Va., to instruction in pediatric radiology at Children's Medical Center, Boston; Lieutenants Gustave T. Anderson of North Platte, Neb., to a residency in dermatology and syphilology at the Naval Hospital, San Diego; Henry G. Wagner of Dayton, Ohio, to a fellowship in research at Johns Hopkins University, Baltimore; Lieutenants (jg) Carleton J. Brown of New London, Conn., to a residency in pediatrics at the Boston Dispensary, Boston; Kenneth A. Parmelee of Stratford, Conn., to a residency in radiology at the Naval Hospital, St. Albans, L. I., N. Y., and William R. True of Bethany, Mo., to a residency in ophthalmology at the Naval Hospital, Bethesda, Md.

### PORTRAIT OF CAPTAIN BAINBRIDGE

A portrait of the late Captain William Seaman Bainbridge, the gift of his widow, was unveiled in the Bureau of Medicine and Surgery July 8. The acceptance was by Rear Admiral C. A. Swanson, the Surgeon General, in the presence of Mrs. Bainbridge, her daughter and two sons and many others from the military and medical professions. Captain Bainbridge, who was one of the first doctors to enter the Navy Medical Corps Reserve, served with distinction in the Expeditionary Forces in the first World War on the French, British and Belgian fronts. During his long period of private practice in New York City, he made hundreds of colored models of cancer of the mouth, face and other parts of the body, and these he willed to the Navy, which has them on display in the Medical Center at Bethesda, Md.

### FIRST ACTIVE DUTY

The following Lieutenants (jg) in the Medical Corps Reserve have been nominated for their first active duty as interns:

J. K. Banks of Raleigh, W. Va., graduate of the University of Arkansas School of Medicine.

Harry S. Binakonsky of Jeannette, Pa., graduate of the University of Pittsburgh School of Medicine.

Donald R. Buechel of Wichita, Kan., graduate of the University of Kansas School of Medicine.

Robert C. Drips of Rochester, Minn., graduate of the University of Arkansas School of Medicine.

Stratton R. Easter of Oakland, Calif., graduate of the St. Louis University School of Medicine.

Robert R. Foster of Portsmouth, Ohio, graduate of the George Washington University School of Medicine.

Jesse M. Hunt Jr. of Wickliffe, Ky., graduate of the University of Louisville Medical School.

Richard A. Lavin of Liverpool, Ohio, graduate of the University of Pittsburgh Medical School.

James J. Lawson Jr. of Arlington, Va., graduate of Tufts College Medical School.

Gilbert L. Nicklas of Baltimore, graduate of the University of Maryland School of Medicine.

Edward A. Schauer of Morrisville, Pa., graduate of Jefferson Medical College.

Bernard C. Smith of Bradford, Ark., graduate of the University of Arkansas School of Medicine.

### NEW REGULAR OFFICERS

The following reserve medical officers on active duty have been appointed to the regular Navy: Capt. John M. Whalen, Grand Rapids, Mich.; Lieut. Comdr. Joseph C. Pinto, Philadelphia, and Lieutenants (jg) Wayne C. Brady, Columbia, S. C.; Duwayne D. Gadd, Saginaw, Mich.; John H. Heald, Billings, Mont.; Paul H. Pennypacker, Pottstown, Pa.; Charles O. Parker, Waycross, Ga., and Donald O. Ward, Roxbury, Mass.

### PERSONALS

The following medical officers have been nominated for duty under instruction in the Navy's Graduate Medical Training Program: Comdr. Richard M. Street, to instruction in otolaryngology at the University of Pennsylvania Graduate School; Lieut. Comdr. Leo S. Madlem Jr., to a residency in psychiatry at the Naval Hospital, Philadelphia; Lieut. (jg) Lyle H. Prenzler, U.S.N.R., to a residency in psychiatry at the Naval Hospital, Philadelphia; Comdr. Thomas E. Cone Jr., U.S.N.R., of Cranston, R. I., to a residency in pediatrics at the Naval Hospital, Philadelphia; Lieut. Comdr. Bruce R. McCampbell to a fellowship in surgery at the Cleveland Clinic.

Dr. Bernard H. Cobetto of Pitcairn, Pa., and Dr. Robert R. Martelle of Beresford, S. D., have been nominated for appointment as lieutenants (jg) in the Regular Navy Medical Corps.

Lieut. (jg) Edward Martin Jr. of Boston has been appointed to the Regular Navy from the Reserve Corps.

Lieut. (jg) Walter C. Reilly Jr. of Glendale, Calif., has been nominated for his first active duty in the Medical Reserve Corps at the Naval Hospital, Long Beach, Calif.

## MISCELLANEOUS

### DR. BRUNER JOINS OAK RIDGE INSTITUTE

Dr. Harry Davis Bruner, professor and head of the Department of Pharmacology, University of North Carolina Medical School, has been appointed principal scientist in the medical division of the Oak Ridge Institute of Nuclear Studies as the no. 2 man in the institute's cancer research program. Dr. Bruner already has moved to Oak Ridge. Although the building to house the medical program is just now under construction, preliminary research problems are being undertaken in an existing wing of the Oak Ridge Hospital.

The Medical Division of the Institute is making a long range study of the treatment of malignant diseases, with particular attention being given to the use of radioactive materials and radiation. The Oak Ridge Institute is comprised of twenty-four Southern universities. It carries out a program of research, training and education in the nuclear sciences through a contract with the Atomic Energy Commission.

Dr. Bruner is the author of many original research papers and has done work on cardiovascular and pulmonary problems. In recent years, he has specialized in radiobiology. He received bachelor of science, doctor of medicine and master of sciences degrees from the University of Louisville, and a Ph.D. degree in physiology from the University of Chicago, studying under Dr. A. J. Carlson.

### ACCIDENTS IN LAKE SUPERIOR IRON ORE MINES

The rising accident trend in the Lake Superior District iron ore mines is reviewed in a publication just released by the Bureau of Mines.

Although the safety record of the district, where 85 per cent of the country's iron ore is produced, was better for the eight year period 1940-1947 than in other metal mining districts, the frequency rate is climbing. Increased production and replacement of men entering the armed services in the 1940-1945 period by men with less experience, and the reentering of the mines by men released from war service during 1946 and 1947 had, and continues to have, "a definite effect on the number of injuries in the mines," according to the report.

Free copies of Information Circular 7510, "Accident Experience Iron-Ore Mines, Lake Superior District 1940-47," may be obtained by writing to the Bureau of Mines, Publications Distribution Section, 4800 Forbes Street, Pittsburgh 13, Pa.

## PUBLIC HEALTH SERVICE

### HOSPITALS FOR DRUG ADDICTS

The two Public Health Service hospitals for drug addicts and mentally ill patients at Lexington, Ky., and Fort Worth, Texas, were transferred July 1, 1949 from the National Institute of Mental Health to the Division of Hospitals, Bureau of Medical Services. The transfer was made as part of the reorganization within the Public Health Service. Dr. Kenneth W. Chapman, formerly clinical director of the Lexington hospital, has been appointed chief of the neuropsychiatric section of the Division of Hospitals, and will serve as liaison officer between the Hospital Division and the National Institute of Mental Health.

### PERSONALS

Dr. Charles F. Blankenship, acting state health officer of Nevada on loan from the Public Health Service since last fall, has been appointed Regional Medical Director of the Federal Security Agency Region 7, with headquarters in Kansas City, Mo., succeeding Dr. Joseph O. Dean, who has been transferred to headquarters in Washington, D. C., as associate chief of the Bureau of State Services.——Dr. Noka B. Hon has been appointed cancer control consultant to the Eastern and Southern States for the National Cancer Institute, replacing Dr. Robert L. Cherry, who has become Assistant Director of the Public Health Division of the ECA Mission to Greece.——Dr. Edward T. Blomquist has been appointed Assistant Chief of the Division of Tuberculosis, U. S. Public Health Service, to succeed Dr. Theodore F. Hilbish, who goes to Johns Hopkins Hospital for special training in radiology.

Surgeon Rheim Jones and Senior Assistant Surgeon Robert C. Rodger have been assigned to Johns Hopkins University for training in otolaryngology and diagnostic bacteriology, respectively; Senior Assistant Surgeon Lynn Fulkerson Jr. has been assigned to the University of Kansas School of Medicine for graduate training in anesthesiology.

# Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

## CALIFORNIA

**Courses for Practicing Physicians.**—Stanford University School of Medicine, San Francisco, will present courses for practicing physicians September 19-23. Registration in all courses is limited and closes September 1. Half-day courses include general surgery, internal medicine, dermatology, fractures, laboratory diagnosis, endocrinology and surgical specialties; full-day courses will be given in anesthesiology and clinical ophthalmology. The fee, $75, is not covered by veterans' educational benefits. Apply to Dean, Stanford University School of Medicine, 2398 Sacramento Street, San Francisco 15.

**University Appointments.**—Two new faculty members have been appointed to Stanford University School of Medicine effective September 1. Dr. Robert H. Alway has been named associate professor of pediatrics, the rank he now holds at the University of Utah College of Medicine, Salt Lake City, where he has been on the faculty since 1943. Dr. Lyman M. Stowe, currently on the staff of the Yale University School of Medicine, New Haven, Conn., has been appointed assistant professor of obstetrics and gynecology. He has been a senior fellow in obstetrics and gynecology at the University of Minnesota Hospitals in Minneapolis. From 1944 to 1946 he was a medical officer in the U. S. Navy.

## COLORADO

**Personal.**—Dr. Harry A. Sauberli, a graduate of Vanderbilt University School of Medicine, 1932, has been appointed state director of local health services for the Colorado State Division of Public Health.

**Southern Colorado Medical Society.**—The organizational meeting for this society was held June 18 in Pueblo. Officers elected are Drs. James Allan Shand, La Junta, president, and Eugene B. Ley, Pueblo, secretary-treasurer. Dr. Tate Miller, Dallas, was the principal speaker at the all day meeting. The society will replace the Arkansas Valley Medical Society, which became inactive during World War II.

## FLORIDA

**Diabetes Service Program.**—The statewide diabetes service program begun in Florida in July by the State Board of Health will follow a pattern of case finding and education established by the U. S. Public Health Service Diabetes Demonstration Unit in Jacksonville. The demonstration unit has proved so successful that the demands for such programs in other sections of the state have been great. There will be testing for diabetes, especially among relatives of diabetic persons, a monthly educational bulletin for diabetic persons and their relatives and classes for diabetic persons in county health departments. There will continue to be free insulin for diabetic persons who cannot afford to purchase the drug.

## ILLINOIS

**Abolish Two State Posts.**—The positions of state surgeon and state supervising dentist in the state public welfare department were discontinued August 1. Services will be transferred to other members of the department staff. Dr. Frederick Gruneck of Chicago has been state surgeon and Charles L. Daniels, D.D.S., of Aurora, has been supervising dentist since 1940.

### Chicago

**Chairman of Professional Faculty.**—Dr. Percival Bailey, professor of neurology and neurologic surgery, University of Illinois College of Medicine, has been reelected chairman designate of the Professorial Faculty of the University of Illinois' Chicago Professional Colleges. The principal purpose of the Professorial Faculty is to bring about closer cooperation between the staff of the Chicago and the Urbana campuses of the University of Illinois.

**The Tumpeer Scholarship.**—A gift of $10,000 has been made to the Chicago Medical School to establish the Dr. I. Harrison Tumpeer Subsidiary Scholarship. The late Dr. Tumpeer, a graduate of Rush Medical College, was professor and head of the pediatric department at the Post Graduate Medical School and Hospital. He was also adjunct pediatrician of the Michael Reese Hospital, organizer and director of the pediatric department of the hospital's dispensary and attending pediatrician. He organized 11 clinics and was credited for the rapid development of the medical library at Michael Reese before his death in November 1939. The scholarship is among the first received under a new subsidiary scholarship plan created by the Chicago Medical School to subsidize the education of a medical student for four years.

**Reopen Clinic for Alcoholism.**—Under the auspices of the Chicago Committee for Alcoholism, which was founded by a group of physicians and civic leaders headed by Anton J. Carlson, Ph.D., the Portal House outpatient clinic has been recently reopened at 100 East Chicago Avenue as a treatment and information center. Under the medical directorship of Dr. Edward C. Frank each patient receives a diagnostic study, which includes a medical, psychologic and psychiatric evaluation followed by individual and group therapy for alcoholism. The final objective of treatment is total rehabilitation. Information on alcoholism is now available at the clinic as well as a free course of orientation lectures and discussions. The clinic, supported in part by a U. S. Public Health Service grant, is accepting voluntary contributions.

## MARYLAND

**Industrial Vision Service.**—A new industrial vision protective service designed to promote the visual efficiency and safety of workers in Baltimore plants has been put in operation by the Maryland Society for the Prevention of Blindness in cooperation with local and industrial groups. Service includes an eyesight-screening examination of the workers. The service is designed primarily to be available at the request of plant managers who employ 200 workers or less. Findings of surveys will make it possible to learn of visual deficiencies and to initiate needed professional and protective care.

**District Health Building.**—Ground was broken in Baltimore June 2 for the Southern Health District building, the first district building erected expressly for the use of the city health department. It is located in a section containing many industrial plants. The two story building will serve as the administrative center for the district health officer, the nursing staff and other district personnel and will house clinics for well baby, prenatal, tuberculosis and venereal disease services. The plans also call for an auditorium which will serve as a meeting place for community groups concerned with health.

## MISSOURI

**Krueger Memorial Fund.**—The will of Dr. Owen W. Krueger, Kansas City, Mo., who died May 20, provided that $10,000 be given to the building fund of the Jackson County Medical Society and that $1,000 be given to the Library Fund to purchase books. The legacies were presented by Mrs. Krueger to Dr. Caryl R. Ferris, Kansas City, at the executive office of the society. The society's finance committee recommended that the amount for the building fund be invested in U. S. Government Bonds and should be continued as the Owen W. Krueger Memorial Fund until the society shall use the funds to purchase a building.

## NEW MEXICO

**Appoints Executive Secretary.**—The New Mexico Medical Society has appointed Mr. Ralph R. Marshall as its first full time executive secretary. The new executive office will be located at 4852 Southern Avenue, Albuquerque.

**Society News.**—A meeting of the New Mexico Clinical Society was held at the Veterans Administration Hospital in Albuquerque July 18. Dr. Merl J. Carson, St. Louis, spoke on the "Use of Angiocardiography in the Study of Congenital and Acquired Heart Disease." This was a joint meeting with the professional staff of St. Joseph's Sanatorium and Hospital in Albuquerque.

## PENNSYLVANIA

**Summer Seminar at Hershey.**—The Pennsylvania Academy of General Practice will hold its summer seminar at the Hershey Hotel, Hershey, August 20. Dr. Elliot P. Joslin, emeritus professor of clinical medicine, Harvard Medical School, Boston, will speak on "The Treatment of Diabetes Mellitus," and Dr. Robert B. Greenblatt, professor of endocrinology, University of Georgia, Augusta, will speak on "Functional Uterine Bleeding." There is no registration fee, and the meeting is open to all physicians who are members of the American Medical Association.

**Meeting of Pathologists and Cancer Society.**—A meeting of the Pennsylvania Association of Clinical Pathologists, the Middle Eastern District of the College of American Pathologists, the Clinical Pathological Society of Pittsburgh and the Allegheny County Division of the American Cancer Society will be held in Pittsburgh September 23 at the Roosevelt Hotel. The program includes a slide seminar on "Cytologic Diagnosis of Cancer of the Lung," with Dr. Peter A. Herbut, Philadelphia, as moderator. The registration fee is $3. There will be available 75 sets of slides, which will be mailed to registrants two weeks before the meeting. The registration fee of $3 for the slide seminar should be sent to Dr. Elwyn L. Heller, Secretary, Department of Pathology, University of Pittsburgh, Pittsburgh.

### Pittsburgh

**Second Symposium on Orthopedic Appliances.**—The Mellon Institute of Industrial Research will again join with the University of Pittsburgh School of Medicine in holding a Second Annual Symposium on Orthopedic Appliances at the institute during the week of September 19. The second symposium, also sponsored by the Sarah Mellon Scaife Foundation through its Multiple Fellowship on Orthopedic Appliances in the institute, will be open to invited orthopedic physicians and surgeons as well as to selected orthopedic technologists skilled in brace design, fitting and construction. The symposium's lecture staff will include nationally recognized authorities in orthopedics as well as scientists of Mellon Institute. They will give detailed attention to bracing problems in cerebral palsy, paraplegia and hemiplegia resulting from poliomyelitis and other disabling diseases, to scoliosis and related spinal conditions and to other specialized orthopedic problems. Inquiries concerning attendance and program details should be addressed to the Orthopedic Appliance Fellowship, Mellon Institute, 4400 Fifth Avenue, Pittsburgh 13, Pa.

## WEST VIRGINIA

**Heart Association Meeting.**—Dr. Paul D. White, Boston, will be the guest speaker at an open meeting of the West Virginia Heart Association September 29 in the Charleston High School auditorium. A clinic will be held September 30 at the Daniel Boone Hotel and will be followed by a business meeting and dinner for physicians and nonphysician members of the association.

**Appoint Medical Director of Compensation Fund.**—Dr. James L. Vickers of Greenwich, Conn., has been appointed by Compensation Commissioner Curtis B. Trent Jr. as medical director of the Workmen's Compensation Fund, succeeding Dr. William T. Henshaw, who died April 13. Dr. Vickers, a native of Huntington, has been engaged in the practice of surgery at Greenwich for several years. Previously he had been identified with the medical department of the New York and Wisconsin workmen's compensation funds. He is a graduate of Johns Hopkins University School of Medicine, 1924.

## WISCONSIN

**Dr. Bradley Made Emeritus Professor.**—Harold Bradley, Ph.D., was made emeritus professor of physiologic chemistry of the University of Wisconsin July 16. Dr. Bradley received a bachelor's degree at the University of California and a Ph.D. at Yale. He came to Wisconsin in 1906. In addition to many years of service to the university, he and his wife have given to the university, in memory of their daughter, Mary Cornelia, the Bradley Memorial Hospital.

**Coordinator of Postgraduate Medical Education.**—Dr. Robert C. Parkin, Chicago, has been appointed assistant professor of clinical medicine and coordinator of postgraduate medical education at the University of Wisconsin Medical School, Madison. He will direct and develop the postgraduate program of training started by the late Dr. Llewellyn R. Cole. Dr. Parkin received his M.D. degree from the university in 1943 and served in the recent war; after his discharge from the Army he practiced for two years in New Albin, Ia., before joining the staff of the Council on Medical Education and Hospitals of the American Medical Association.

## HAWAII

**Society of Neurology and Psychiatry.**—Twenty-three physicians met recently in Honolulu to organize the Society of Neurology and Psychiatry of Hawaii. A constitution was formally adopted on April 13, 1949. Officers are Dr. Richard E. Kepner, Honolulu, president; Dr. Thomas S. Bennett, Honolulu, vice president, and Dr. H. Joseph Simon, Honolulu, secretary-treasurer. Meetings are held on the second Wednesday of alternate months.

## GENERAL

**Pan-American Doctors Club Meeting.**—This group will hold a symposium on tuberculosis August 14-15 in San Miguel Regla, Huasca, Hidalgo, Mexico. Dr. Henry J. Zettelman, 636 Church Street, Evanston, Ill., is program chairman.

**Send Respirators to Eleven States.**—With reported cases of poliomyelitis running over 1,000 more for this year than for the corresponding period last year, the National Foundation for Infantile Paralysis by July 23 had sent 60 items of medical equipment, including 30 respirators to 17 states, principally to Arkansas and Indiana, recruited 70 nurses and 9 physical therapists for epidemic duty in 12 states and provided financial aid totaling $112,298 to 29 counties in 16 states.

**Prevalence of Poliomyelitis.**—Reports of cases of poliomyelitis for the periods indicated have been received from the Division of Public Health Methods, U. S. Public Health Service:

| | Week Ended | | | Total to | | Total * | |

* Last two columns show reported incidence since approximate average seasonal low: 18 weeks.

**Courses in Laboratory Diagnosis.**—The U. S. Public Health Service will give the following refresher courses in laboratory diagnosis September 12 to December 16:

Laboratory Diagnosis of Parasitic Diseases (6 weeks) September 12 to October 21.
Laboratory Diagnosis of Bacterial Diseases, Part 2, and General Bacteriology (5 weeks) October 31 to December 2.
Laboratory Diagnosis of Rabies (1 week) November 14 to November 18.
Advanced Enteric Bacteriology (2 weeks) December 5 to December 16.

Information and applications should be requested from the Chief, Laboratory Division, Communicable Disease Center, 291 Peachtree Street N.E., Atlanta, Ga.

**Mississippi Valley and Medical Writers' Meetings.**—The Mississippi Valley Medical Society will hold its annual meeting at the Jefferson Hotel, St. Louis, September 28-30, under the presidency of Dr. Alphonse McMahon, St. Louis. Over 30 clinical teachers from leading medical schools will conduct the postgraduate assembly, which is planned to appeal to general practitioners. There is no registration fee, and all ethical physicians are invited to attend. The American Medical Writers' Association will hold its annual meeting September 28. In the afternoon a two hour course of instruction in medical writing will be conducted by Dr. J. F. Hammond, associate editor, Journal of the American Medical Association, Chicago. Other speakers include Dr. Howard A. Rusk, New York, and Foster Eaton of the St. Louis Star-Times. Information on these meetings may be obtained from Dr. Harold Swanberg, Secretary, Mississippi Valley Medical Society, 209-224 W. C. U. Building, Quincy, Ill.

**Fellowships in Cancer Research.**—The Committee on Growth of the National Research Council, acting for the American Cancer Society, is entertaining applications for grants and fellowships. Applications for new grants in cancer research will be received until October 1. Investigators now receiving grants will be notified individually regarding application for the extension of these grants. Final decision on applications will be made in most cases soon after February 1. Grants approved at this time ordinarily will become effective July 1, 1950. Fellowship applications may be submitted at any time. Those received prior to October 1 will be acted on in December by the Committee on Growth. Those received between October 1 and March 1 will be acted on in April. Fellowships ordinarily will begin July 1, though this date may be varied at the request of the application. During the past year the American Cancer Society, Inc., on recommendation of the Committee on Growth, has approved research grants and fellowships totaling over $2,000,000. Communications regarding grants and fellowships should be addressed to Executive Secretary, Committee on Growth, National Research Council, 2101 Constitution Avenue N.W., Washington 25, D. C.

**Distribution of Cyclotron-Produced Radioisotopes.**—Cyclotron-produced radioisotopes will be made available to research men in the United States under a program announced July 23 by the Atomic Energy Commission. They will be used to apply to problems in general science, medicine, industry and agriculture. The program will augment the present distribution of reactor-produced radioisotopes, which has been in effect since August 1946. Six thousand, nine hundred and seventy-five shipments of radioisotopes of nearly 60 elements representing nearly 100 isotopic species have been made for research purposes through the facilities of the Atomic Energy Commission. Only those cyclotron-produced isotopes having half-lives of more than 30 days will be distributed initially. Included in these are 43 day beryllium 7, 3 year sodium 22, 44 day iron 59, 4 year iron 55, 250 day zinc 65, 90 day arsenic 63, and 56 day iodine 125. Other cyclotron-produced radioisotopes of significant value as tools of research may be added at a later date.

The Isotopes Division, Atomic Energy Commission, Oak Ridge, Tenn., will carry out the allocation function in the same manner as it now does with reactor-produced isotopes.

Cyclotron-produced radioisotopes, because of the method of their manufacture, are more expensive than reactor-produced isotopes, and, in order to price them at a level which will make them available to most research institutions, it will be necessary for the commission to subsidize the program to a certain extent. In addition, these isotopes will be made available free of all production charges for cancer research. Distribution of materials produced under this program will be limited to institutions and organizations within the United States and its territories and possessions.

**Million Dollar Libel Suits Announced.**—Dr. Anton J. Carlson, Chicago, president of the National Society for Medical Research, announced July 24 that two one million dollar libel suits have been filed by medical scientists against the Hearst Publishing Company, Inc., publisher of the Chicago *Herald American*, and William Randolph Hearst of San Simeon, Calif. One million dollars for punitive and compensatory damages is being asked by Nathan R. Brewer, D.V.M., Ph.D., of the University of Chicago in a libel suit filed in the U. S. District Court. Dr. Virgil H. Moon of Bowman Gray School of Medicine of Wake Forest College, Winston-Salem, N. C., filed suit for a million dollars the previous week as the result of a news story printed in the Chicago *Herald American* which "maliciously misrepresented his views on animal experimentation" May 24 and May 29 of this year. Both suits were filed against the Chicago newspaper within ten days as the result of that paper's campaign against a bill before the Illinois General Assembly to provide that condemned animals from the pounds in the state be made available to medical institutions.

"Two other suits are pending, and others will follow if necessary," Dr. Carlson said. "This is the beginning of a policy which took shape when a nationwide legal committee was formed by the National Society for Medical Research to advance medical research and to protect the medical worker and his institution against what appears to be an organized program to villify and slander medical science and scientists." The newly formed Legal Committee for Medical Research includes the attorneys and counsel of leading colleges, universities and medical institutions throughout the country, and representatives are located in every state.

**Congress of Physical Medicine.**—The annual session and instruction seminar of the American Congress of Physical Medicine will be held at the Netherland Plaza, Cincinnati, September 6-10. Numerous round table discussions will be presented. Those speaking by invitation include:

Bruce C. Martin, Columbus, Ohio, Use of Skin Grafts in Rehabilitation.
Harry D. Bouman, Madison, Wis., Treatment of Hyperhidrosis by Electric Current.
Francis X. Sweeny, Philadelphia, and Steven M. Horvath, Ph.D., Philadelphia, Infra-Red Heating of Tissues.
Laurence E. Morehouse, Ph.D., Los Angeles, Physiology of Exercise.
Alexander Sandow, Ph.D., New York, Latent Period of Muscular Contraction.
Fay A. LeFevre, Cleveland, Physical Medicine and Peripheral Vascular Disease.
Louis Daily Jr., Khalil G. Wakim, Julia F. Herrick, Edith M. Parkhill and William L. Benedict, Rochester, Minn., Effects of Microwave Diathermy on the Eye: An Experimental Study.
Earl D. McBride, Oklahoma City, Disability Evaluation.
Edward B. Schlesinger, New York, Rationale and Use of Muscle Relaxants in Neuromuscular Disorders.
Glenn Gullickson, Minneapolis, Study of the Effect of Unilateral Paralysis of the Lower Extremity on Bone Growth.
George H. Bishop, Ph.D., and Margaret Clare, R. P. T., St. Louis, Analysis of Periodic Muscle Activity in Experimental Animals.
Ludwig W. Eichna, Adolph R. Berger and Bertha Rader, New York, Measurement of Intracardiac and Intravascular Temperatures and Their Comparison with Rectal Temperature.
Robert L. Bowman, New York, Some Factors Influencing the Effect of Liquid-Borne Ultrasound on Biological Systems.

A Symposium of Hydrotherapy will be conducted Friday morning and a Symposium on Poliomyelitis in the afternoon. The annual dinner will be Thursday at 7 p.m.

## Marriages

WILLIAM LESLIE MACVANE JR., Togue, Maine, to Miss Margaret Elizabeth Owen of Hallowell, June 4.

SAMUEL WARD CASSCELLS, Wilmington, Del., to Miss Sarah O. Dyson in Charlottesville, Va., June 11.

ROBERT FLEMING HAGERTY, Durham, N. C., to Miss Mary Louise Leffelman of Stateburg, S. C., June 4.

WILLIAM BRADFORD DE MOND, Greenfield, Mass., to Miss Margaret Virginia Weber of Denver, June 9.

WALLACE E. MILLER, Indianapolis, to Miss Beverly Dahn Welsh in Crawfordsville, Ind., May 29.

CHESTER AMOS HAUG, Rochester, N. Y., to Miss Mary Elizabeth Penn of Massena, May 14.

WALTER BURT GRENELL, Chicago, to Miss Marion L. Baskette of Pontiac, Mich., May 28.

FRANCIS J. GILROY, Edgewater, N. J., to Miss Mary M. Shay of Tompkinsville, N. Y., June 11.

STEWART MCCRACKEN, Philadelphia, to Miss Joan Adamson Fernley at Whitemarsh, June 11.

VICTOR A. MCKUSICK, Baltimore, to Miss Anne Bishop in Rochester, N. Y., June 11.

HANS LEHFELDT to Miss Maria Eisner, both of New York, May 15.

# Deaths

**Elias William Abramowitz** ⊕ New York; born in 1885; University and Bellevue Hospital Medical College, New York, 1907; clinical professor of dermatology and syphilology at the New York Post-Graduate Medical School and Hospital, New York University–Bellevue Medical Center; formerly on the faculty of Columbia University College of Physicians and Surgeons; founding member of the American Board of Dermatology and Syphilology; member of the American Academy of Dermatology and Syphilology and the American Dermatological Association; founder, past president and honorary member of the Brooklyn Dermatological Society; member and formerly chairman of the Manhattan Dermatological Society; member and formerly vice president of the Society for Investigative Dermatology; fellow and advisory board member of the New York Academy of Medicine; formerly corresponding member of the French Society of Dermatology and the German Dermatological Society; chief dermatologist of the Israel-Zion Division of Maimonides Hospital in Brooklyn; attending dermatologist to the New York Post-Graduate Hospital; attending dermatologist and syphilologist at the New York Skin and Cancer Hospital; director of dermatology and syphilology at the Gouverneur Hospital and the Jewish Memorial Hospital; during World War I a member of the Council of National Defense and an instructor in an intensive course in dermatology at Columbia under Army and Navy auspices; on the advisory board, Selective Service, during World War II; died June 13, aged 63, of hypernephroma with metastases.

**Walton Martin** ⊕ New York; born in Staten Island, N. Y., Feb. 4, 1869; College of Physicians and Surgeons, medical department of Columbia College, New York, 1892; clinical professor emeritus of surgery at his alma mater; member of the founders group of the American Board of Surgery; member of the American Surgical Association; fellow of the American College of Surgeons; on the staff as consulting surgeon and member of the board of managers of St. Luke's Hospital; co-author of "Chemistry and Physics"; revised T. H. Green's "Introduction to Pathology and Morbid Anatomy" in 1898; one of the translators and editors of Dr. E. Von Bergmann's "System of Practical Surgery"; died at his summer home in Cornwall, Conn., June 18, aged 80, of cerebral hemorrhage.

**Frank Harrell Redwood** ⊕ Norfolk, Va.; Medical College of Virginia, Richmond, 1913; specialist certified by the American Board of Psychiatry and Neurology, Inc.; fellow of the American College of Physicians; past president of the Norfolk County Medical Society; member of the Southern Psychiatric Association, American Psychiatric Association and the Association for Research in Nervous and Mental Diseases; formerly vice president of the Seaboard Medical Association; served during World War I; affiliated with Norfolk General Hospital, St. Vincent's Hospital and De Paul Hospital; at one time associated with the U. S. Public Health Service; died in New York May 27, aged 58.

**James Arthur Attridge** ⊕ Port Huron, Mich.; Detroit College of Medicine, 1897; past president of St. Clair County Medical Society; fellow of the American College of Surgeons; died May 22, aged 78, of cerebral hemorrhage.

**Lyle Cholwell Bacon** ⊕ St. Paul; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1890; an Associate Fellow of the American Medical Association; died June 4, aged 83, of cerebral hemorrhage.

**Theodore Prudden Bailey**, Albany, N. Y.; College of Physicians and Surgeons, medical department of Columbia College, New York, 1880; member of the American Medical Association; affiliated with St. Peter's Hospital, where he died May 22, aged 91, of bronchopneumonia and uremia secondary to benign prostatic obstruction.

**Walter Hays Baker** ⊕ South Bend, Ind.; Indiana Medical College, School of Medicine of Purdue University, Indianapolis, 1907; specialist certified by the American Board of Surgery; fellow of the American College of Surgeons; affiliated with Memorial and St. Joseph's hospitals; died June 6, aged 72, of cerebral aneurysm.

**John Houston Barnett**, Marlin, Texas; Vanderbilt University School of Medicine, Nashville, 1909; member of the American Medical Association; past president of Falls County Medical Society; affiliated with Buie-Allen Hospital, where he died May 27, aged 64, of asthma.

**Robert Lander Bartlett** ⊕ Warm Springs, Va.; Tufts College Medical School, Boston, 1897; member of the Medical Society of the State of New York; for many years superintendent of the Oneida County Hospital in Rome, N. Y.; died May 25, aged 74.

**Joseph Franklin Blake**, Chadbourn, N. C.; North Carolina Medical College, Davidson, 1905; died May 27, aged 65, of heart disease.

**Frank William Boadway**, Ardmore, Okla.; Kentucky School of Medicine, Louisville, 1907; member of the American Medical Association; served as vice president of the Oklahoma State Medical Association; died April 17, aged 66, of heart disease.

**David C. Bosserman**, McAllen, Texas; National University of Arts and Sciences Medical Department, St. Louis, 1914; member of the American Medical Association and Missouri State Medical Association; served overseas during World War I; formerly affiliated with Christian Hospital in St. Louis; died in the U. S. Naval Hospital, Corpus Christi, May 23, aged 69, of pulmonary infarction.

**Arthur Harry Bradley**, St. Louis; Marion-Sims College of Medicine, St. Louis, 1892; member of the American Medical Association; died in the Barnes Hospital May 7, aged 79, of carcinoma of the cecum.

**Reed Oshea Brigham** ⊕ Toledo, Ohio; University of Michigan Medical School, Ann Arbor, 1921; died May 23, aged 60.

**Clarence Albert Butler**, Hot Springs, S. D.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1899; member of the American Medical Association; died in the Veterans Administration Hospital May 7, aged 84, of uremia.

**Frederick A. Carpenter** ⊕ Waverly, N. Y.; Eclectic Medical Institute, Cincinnati, 1889; past president of the Tioga County Medical Association; for many years school doctor; affiliated with the Tioga County General Hospital, where he died May 31, aged 93, as the result of a fall.

**Charles Albert Clement**, Rover, Ark. (licensed in Arkansas in 1903); died May 19, aged 74, of carcinoma of the lung.

**James Francis Condrick**, Quincy, Mass.; Tufts College Medical School, Boston, 1919; member of the American Medical Association; died May 27, aged 63.

**Clyde Sumner Culp**, Salineville, Ohio; Western Reserve University Medical Department, Cleveland, 1898; member of the American Medical Association; on the staff of City Hospital in East Liverpool, where he died May 28, aged 75.

**Arthur Hamilton Deekens**, New Orleans; University of Pennsylvania Department of Medicine, Philadelphia, 1889; member of the American Medical Association and the Medical Society of Virginia; served during World War I; died in Richmond, Va., May 29, aged 91, of carcinoma.

**William Joseph Doyle II** ⊕ Wilkes-Barre, Pa.; Jefferson Medical College of Philadelphia, 1932; during World War II served as medical examiner of Wilkes-Barre draft board number 1, and was awarded a Certificate of Merit by the Selective Service System for faithful and loyal service; affiliated with the Mercy Hospital, where he died May 23, aged 41, of intestinal obstruction.

**James Erle Drake** ⊕ Spokane, Wash.; Washington University School of Medicine, St. Louis, 1901; for many years school physician; died April 21, aged 72, of heart disease and hypertension.

**Isaiah Davis Durham**, West Columbia, S. C.; University of Georgia Medical Department, Augusta, 1913; member of the American Medical Association; died May 30, aged 60.

**Sidney Allan Ellis**, Boston (licensed in Massachusetts in 1899); died in May.

**Robert H. Fisher**, Waverly, N. Y.; University of Buffalo School of Medicine, 1895; died in the Robert Packer Hospital, Sayre, Pa., May 26, aged 76.

**Charles Joseph Folz** ⊕ Evansville, Ind.; Indiana University School of Medicine, Indianapolis, 1923; county coroner; served during World War I; died June 16, aged 53.

**Harold Hemmingway Foreman** ⊕ Akron, Ohio; Howard University College of Medicine, Washington, D. C., 1933; died June 21, aged 41.

**Edwin Rolander Fouts**, Ryegate, Mont.; Beaumont Hospital Medical College, St. Louis, 1892; member of the American Medical Association; died in Billings June 2, aged 79, of cerebral hemorrhage.

**William L. Gambill** ⊕ Ashland, Ky.; Hospital College of Medicine, Louisville, 1901; fellow of the American College of Surgeons; affiliated with King's Daughters' Hospital; died June 14, aged 70, of hepatitis.

**Walter Wesley Goddard** ⊕ Miami, Fla.; Albany (N. Y.) Medical College, 1894; an Associate Fellow of the American Medical Association; member of the Medical Society of the State of New York; at one time practiced in Schenectady, N. Y., where he was affiliated with the Eastern New York Orthopedic Hospital-School "SunnyView"; died in the Jackson Memorial Hospital April 26, aged 76, of cerebral embolus, arteriosclerosis and bronchiectasis.

**John Hansen** ⊕ Glenbeulah, Wis.; Milwaukee Medical College, 1904; died June 1, aged 76.

**Harry Haver Hatcher,** Stamford, Conn.; Starling Medical College, Columbus, 1896; fellow of the American College of Surgeons; at one time practiced in Dayton, Ohio, where he was for many years county coroner, and on the staffs of Dayton State Hospital and St. Elizabeth Hospital; died May 25, aged 74.

**Chessman Palmer Hutchinson,** Danielson, Conn.; Baltimore Medical College, 1893; member of the American Medical Association and the Massachusetts Medical Society; died April 13, aged 88.

**George Samuel Isaacs,** Donora, Pa.; University of Pittsburgh School of Medicine, 1948; served during World War II; intern at St. Francis Hospital in Pittsburgh, where he died May 14, aged 26, of acute leukemia.

**John Frank Jonas,** Marion, N. C.; Baltimore Medical College, 1903; member of the American Medical Association; past president of the McDowell County Medical Society and the Tenth District Medical Society; for many years county coroner; died May 28, aged 76.

**Edward Howard Jones,** Weyauwega, Wis.; Rush Medical College, Chicago, 1883; served as a member and president of the school board; for many years affiliated with Waupaca County Hospital; died recently, aged 89.

**Fred Willis Kettlestrings,** Oak Park, Ill.; Rush Medical College, Chicago, 1895; member of the American Medical Association; died in July, aged 81.

**Harold Arthur Kirkham** ⊕ Major, U. S. Army, retired, Detroit; Detroit College of Medicine and Surgery, 1913; served during World War I; entered the medical corps of the U. S Army on July 1, 1920; retired Nov. 30, 1933; died in Jennings Hospital May 16, aged 62.

**Arthur William McArthur,** Lincoln, Calif.; McGill University Faculty of Medicine, Montreal, Quebec, Canada, 1896; served during World War I; local health officer and school physician; on the staffs of the Mercy Hospital and Sutter Hospital, Sacramento, where he died April 28, aged 76, of coronary occlusion.

**Rufus Martin** ⊕ Warren, Ark.; University of Nashville (Tenn.) Medical Department, 1907; served during World War I; on the staff of Hunt Hospital; died April 15, aged 68, of carcinoma of the throat.

**Bernard I. Mills** ⊕ Maywood, Neb.; Lincoln Medical College of Cotner University, 1908; on the staff of St. Catherine of Sienna Hospital; died May 5, aged 64, of coronary occlusion.

**Marion Bailey Murdock** ⊕ Eastland, Texas; Medical College of Virginia, Richmond, 1943; served during World War II; killed in June, aged 31, in a plane crash.

**Austin Joseph O'Leary,** Tacoma, Wash.; Rush Medical College, Chicago, 1905; served during World War I; died May 19, aged 67, of coronary thrombosis.

**Louis Micheal Palermo,** Bronxville, N. Y.; New York Homeopathic Medical College and Flower Hospital, New York, 1928; member of the American Medical Association; specialist certified by the American Board of Surgery; fellow of the American College of Surgeons; assistant professor of surgery at the New York Medical College, Flower and Fifth Avenue Hospitals in New York, where he was on the staff of the Metropolitan Hospital; died May 8, aged 46.

July 1, 1949.

### "Free" Medicine Costs 64 per Cent More

The high cost of administration of the "free" medicine scheme has been revealed by figures recently released. The Australian government paid for 247,475 medical prescriptions for the twelve months ending May 31, 1949. For the eleven months to April 31, the government had paid the drug stores $156,025. But in salaries and general expenses, $97,907 had been absorbed to administer this payment. This meant that the cost of each medical prescription had been increased by 64 per cent. The average cost for the drugs and dispensing of each prescription was 65 cents; the administrative cost was 43 cents, making a total of $1.08 per prescription.

It is estimated that only 45 doctors in private practice, of the 5,500 in Australia, are using the government forms. Doctors employed by the commonwealth government would, of course, be obliged to use the forms. Of the private doctors who are prescribing free medicine, the highest number is in Victoria and the lowest in Queensland. One prescription for 10 ampules of penicillin in oil holds the record for high cost; the government paid $207.

An unexpected complication in the scheme is a serious shortage of medicine bottles due to the coal strike now crippling Australian industry. Drug stores are unable to meet the present demand for fluid containers and would be unable to meet the expected increase in demand under universally "free" conditions.

### Regulations Changed

Under the old regulations, doctors were limited to prescribing specified sizes in mixtures and definite quantities of tablets. These restrictions have been removed by recent regulations, and a doctor may now prescribe the size or quantity which he considers best meets the need of the patient.

The British Medical Association spokesman has said that the fight against free medicine would not be affected by these changes. This concession was regarded as of minor nature and did not affect the doctors' demands for unlimited prescription and freedom from penalties.

No date has yet been fixed for the operation of the regulations compelling doctors to use the government forms for all prescriptions and making them liable to a fine of $160 if they use their personal forms for any prescriptions or any drug in a prescription in the government formulary. In the meantime the government has stated that it will recognize the right of any patient to refuse to accept a prescription on a government form. In that case, of course, the patient would be obliged to meet the cost of the prescription himself.

The government has expressed its confidence in its ability to meet any legal challenge of the validity of the Pharmaceutical Benefits Act that might be instituted by the B. M. A. in the high court of Australia and possibly referred to the privy council in Britain and is at present taking place in reference to the government's banking control legislation.

The government has further announced that regulations are at present being drafted for the general medical benefits scheme whereby half the cost of all private medical services will be paid by the government from its social security funds.

### Low Infant Mortality Rate

Australia's infant mortality rate for 1948 was the lowest ever recorded for any year. The rate per 1,000 live births was 27.77.

It is not clear whether the Australian aboriginal rate is included in these figures. Because of the difficulty of collecting statistics from a nomadic people and the small percentage of surviving aboriginals, the total figure given would not be significantly affected.

New Zealand does not include the Maori population in the published infant mortality figures for that country.

This 1949 rate for Australia is tangible evidence of a slow but steady development of infant welfare services in all states of Australia over the past twenty years. Almost the only limiting factor today, in the development of these services, is the shortage of trained nursing personnel. Australian cities and suburbs are dotted with infant welfare centers to which the mother of the well baby may come for routine weighing and advice. There is a well developed follow-up system which keeps in touch with every newborn baby. In the sparsely populated areas, the railway traveling clinic, the highway mobile service and even the "flying nurse" take care of the Australian infant.

The net increase of births over deaths in Australia is now 100,000 per year. Of 177,963 infants born in 1948, 4,942 died in their first year. As a result of natural increase as well as immigration, the Australian population in the 18 months ending June 30, 1950, would increase by 400,000, compared with 900,000 in the 14 years 1933-1947.

The official population target for Australia is 20,000,000, compared with a present population of 7,500,000. This target is considered to be the minimum necessary for Australia's security and the maximum compatible with the natural resources of the country.

## BELGIUM

July 8, 1949.

### Control of State Medicine

Although in Belgium the socialization of medicine has not reached the degree it has attained in Great Britain, one observes, nevertheless, that the application of the measures of sick and invalidity insurance is abused to such an extent that one can already foresee the ruin of this institution. Without doubt, its aim, to assure equitable medical care to all those in need of it, is laudable; unfortunately, as in all human affairs, everything that is based on infringement of the liberty of the individual is bound to lead to failure.

Already there are heard in Belgium rumors that parliament is considering measures regarding the abuse and frauds committed with regard to sick and invalidity insurance. It has become necessary to take drastic measures to avoid immediate ruin.

These measures are complex, and certain details are unusual and abnormal. It can be foreseen that this structure is decaying as a result of its illogical nature. For example, "The benefit of compensation is denied to the insured who has used a means of transportation other than a common carrier, without authorization of the medical counselor of the insurance organization; the insured who will do, without authorization of the medical counselor of the insurance organization, nonremunerative work, even for himself. Nevertheless, he can do light work if these have not been forbidden by the medical counselor of the insurance organization; the insured who without authorization of the medical counselor will change his residence to go to the seaside, the country or a foreign locality; the insured who will be found in a show or theatre or where drinks are dispensed without authorization of the medical counselor of the insurance organization and outside the hours authorized for leaving the house; the insured who will be found without authorization of the insurance organization outside his domicile or residence in the following hours: 11:30 a. m. to 2 p. m. and 5 p. m. to 8 a. m., during the period extending from October 1 to March 31, 7:30 p. m. to 8 a. m., during the period extending from April 1 to September 30, or who will be found in a drinking establishment during the hours authorized for leaving his domicile; the insured who will be found without authorization of his medical counselor in a show or theater during the hours authorized for going out; the insured who will be found away from his residence more than 15 kilometers, except on authorization of his insurance organization and a definite cause."

A reporter commented on this example: "It is just to recognize that, in making these rules, the authorities respond to their duty to the public to combat dishonesty and exploitation of unfortunate situations. To condemn the insured who does this is well and good, but is one not exaggerating when, for going out in a private vehicle of transportation (a bicycle perhaps), or to kill his boredom by passing an hour in the cinema, one must furnish authorization by a medical counselor? The most important matter is, after all, that an exact diagnosis makes it clear that the person is really an invalid or a patient."

It seems that in Belgium the law on sick and invalidity insurance is entering into a phase of existence where ridicule can kill it.

### Hepatitis Due to Human Serum

At the Society of Medical Sciences of Luxemburg, S. Hertz has published a study on hepatitis caused by human serum. This new disease has acquired theoretic and practical importance. It has been the starting point of investigations which have led to the experimental demonstration of the infectious nature of hepatitides and of the existence of nonicteric forms of these infectious hepatitides. The frequency and gravity of these forms of icterus make necessary a strict revision of indications for the transfusion of blood and plasma. The product employed plays an important role. The incidence of icterus is especially large when dry plasma is employed. These facts are important from the prophylactic point of view and should be taken into consideration when a blood bank is organized.

Hepatitis due to human serum is due to a filtrable icterogenic virus which resembles, if it is not identical with, the virus of spontaneous hepatitis. It is seen especially after the transfusion of plasma. Its lesions are identical with those found in other infectious and toxic hepatitides. In the clinic they present a picture of hepatitis, with or without jaundice, which may lead to cirrhosis.

### Tuberculosis and Pregnancy

Dr. Francisco Cerruti, assistant dean of Escola Paulista de medicina, recently published a symposium on tuberculosis and pregnancy according to the data obtained by the practitioners of the Maternidade de São Paulo. Dr. Cerruti made the following conclusions:

1. Pregnancy has little influence on the evolution of tuberculosis, especially when the tuberculosis is being treated.

2. Interruption of pregnancy does not improve the evolution of the bacillary process.

3. Pregnancy should not be interrupted, but intensive modern physical therapy should be used, as pregnancy does not restrict the full action of collapse therapy, and eventually streptomycin should be used.

4. There is no advantage in interruption of pregnancy in the advanced forms of tuberculosis.

5. In cases of initial evolutive forms which, after intensive collapse therapy in the first three months of pregnancy, have not shown improvement, abortion is indicated. These are rare clinical occurrences.

6. An abortion should never be performed after the third month of pregnancy.

7. For all practical purposes congenital tuberculosis does not exist, nor do hereditary dystrophies or hereditary predispositions, so that the child of a tuberculous woman, as a biologic and social entity, is equal to the child of a healthy mother if it is immediately protected from exposure.

8. Premature delivery is commoner than abortion in a woman with tuberculosis.

9. Hyperemesis and toxemia are rare in the pregnant women with tuberculosis.

10. Delivery in a tuberculous woman is more rapid and less painful.

11. The delivery should be attended in a manner which is easy, short, nonexhaustive and nontraumatic.

12. The delivery should be spontaneous when easy; if there is dystocia, it is preferable to shorten labor within obstetric possibilities, without waiting as long as in the case of a healthy pregnant woman.

13. The tuberculous patient has a tendency to postpartum hemorrhage.

14. The tuberculous woman is prone to hemorrhage; she must be attended immediately at the first sign of shock.

15. The mortality rate is relatively high during the postpartum period.

16. As a rule, a tuberculous woman should not nurse her baby.

17. BCG vaccine should be given to newborn infants.

18. It is advisable that those who have had small lesions of the productive type should become pregnant only one or two years after clinical cure, and those who have shown the exudative form should not become pregnant for a period of three or four years.

### Biliary Lithiasis

Dr. Saulo de Moura Costa, who has been assisting in the clinic of Prof. Benedito Montenegro, has completed a study on biliary lithiasis with observations on some cases in which the operative treatment was performed. He stated that early operation is considered essential for best surgical results, as in cases of long-standing disease there are associated lesions, some of which cannot be directly reached by the surgeon. He reviewed the operative cholangiographic aspects, presenting statistics of 342 cases from Professor Montenegro's private clinic. Commenting on these statistics he pointed out that in the same service the percentage of choledocholithiasis, which was 10 per cent before the cholangiographic process was in use, rose to 15 per cent after the use of this process. Besides, it has the merit of avoiding the opening of the choledochus, which is slightly dilated and which many surgeons open based on a mere suspicion. He further treated pancreatitis and stenosing odditis, in which operative cholangiography is particularly effective, indicating the cases in which drainage of the biliary tracts should be done.

### Routine Appendectomy in Gynecologic Laparotomy

An inquiry was held by Prof. Alicio Peltier de Queiroz, of the Faculdade de Medicina of Salvador, Baia, on the routine performance of appendectomy in gynecologic laparotomy. According to the replies and to his own opinion, Professor Queiroz concludes: (*a*) Almost all cecal appendixes are the site of microscopic lesions of involutive and inflammatory type; (*b*) There is no relation of cause and effect between those lesions and the condition known as "chronic appendicitis."

(*c*) A review of reciprocal relations between gynecologic conditions and appendiceal ones dismisses old beliefs still pending in many surgical minds. (*d*) It is not logical and tenable after all these facts to practice routine appendectomy in the course of gynecologic laparotomy in the present state of knowledge.

# Correspondence

## EMOTIONAL STIMULI AND EFFECTOR ORGANS

*To the Editor:*—In the conclusion of the article "Some Effects of Myanesin in Psychiatric Patients" (J. A. M. A., June 25, 1949) the authors, Schlan and Unna, state that myanesin® (tolserol®) (3-ortho-toloxy-1,2-propanediol) is the only drug that allays anxiety without clouding consciousness. For the last few years efforts have been made to prevent stimuli originating in the emotional centers of the central nervous system from reaching the effector organs. Already there are: (1) an adrenolytic drug, dibenamine (N,N-dibenzyl-beta-chloroethylamine) (Rockwell, F. V.: Dibenamine Therapy in Certain Psychopathologic Syndromes, *Psychosom. Med.* **10:** 230 [July-Aug.] 1948), and (2) a thyroid inhibitory drug, propylthiouracil (Jonas, A. D.: Propylthiouracil in the Treatment of the Anxiety State, *Med. Rec.* **161:** 422 [Aug.] 1948). Obviously, there are many more drugs with similar effect awaiting discovery. I mention here only an anticorticotropic and an antithyrotropic compound.

A. D. Jonas, M.D., New York 58.

## ESTIMATION OF URINARY SODIUM

*To the Editor:*—In The Journal of June 25 appeared an article by Bryant and his co-workers entitled "Estimation of Urinary Sodium." Certain misconceptions and questionable features should be discussed publicly, lest they aid in perpetuating ideas and practices now considered out of date.

The authors state that daily determination of sodium is expensive and so complicated as to be prohibitive even in the hospitalized patient. The flame photometer, though expensive, is a simple and relatively accurate instrument and is in wide current use. For those institutions where the equipment and technical help for this machine are not available, there are extremely simple and accurate chemical methods which do not require special equipment (Goldzieher, J. W., and Stone, G. C. H.: *J. Clin. Endocrinol.* **9:** 95-100, 1949) and are not expensive.

The authors base their test on old data which showed that sodium and chloride excretion run roughly parallel in certain special cases. The general inapplicability of such a concept is, however, well known among physiologists and is attested by the authors' own data when comparing their figures from flame photometric measurements and Volhard chloride determinations. Nearly all recent workers in cardiac physiology have recognized that chloride determinations cannot be used to study sodium metabolism; this was recently emphasized by a careful balance study (Goldzieher, J. W., and Stone, G. C. H.: *J. Clin. Endocrinol.* **9:** 368-371, 1949). The whole modern concept of electrolyte balance, as summarized so aptly by Gamble, has pointed out repeatedly that such technics are specious and wholly unsatisfactory and that the concept of "sodium chloride" as an entity, without consideration of total acid-base balance, is totally erroneous. The entire basis of this estimation of "urinary sodium" is therefore unreliable. Moreover, the title seems rather inappropriate and should have read, perhaps, "Estimation of Urinary Chloride."

Even if this fundamental problem did not exist, the value of the technic is open to question. The authors' data indicate that: (1) a sodium range of 25 to 29 mg. may require 1 to 4 drops of solution (a 400 per cent error); (2) 2 drops of reagent may indicate anything from 11 to 150 mg. of sodium per liter and 13 drops may represent anything from 330 to 820 mg. of sodium per liter, and (3) levels of 50 to 70 mg. of sodium per liter are estimated by this test at anything from 100 to 700 mg. (a 700 per cent error).

Any test, no matter how convenient, which is subject to a 700 per cent error in qualified hands is meaningless. In such circumstances it seems probable that careful inquiry by the physician or the recording of dietary intake by the patient would be far more likely to reveal actual errors in the control of sodium intake.

Joseph W. Goldzieher, M.D., New York.

## MYOCARDIAL INSUFFICIENCY

*To the Editor:*—I refer to the excellent article by Dr. George R. Herrmann on myocardial insufficiency in The Journal of June 11. On page 509 is a statement referring to the direct application of the Fick principle: "Cardiac output equals the total oxygen consumption per minute divided by auricular-ventricular oxygen difference times 100." I would appreciate your clarifying whether it should not be "arteriovenous" instead of "auricular-ventricular."

The routine application of the Fick principle in measuring cardiac output was always based on the difference between the oxygen contents or carbon dioxide contents in arteriovenous blood samples. It may be that the venous catheterization of the right atrium, right ventricle and pulmonary artery introduced a new method in measuring the cardiac output. Your explanation on the subject will be greatly appreciated.

Thaddeus D. Labecki, M.D.
Director, Sunflower County Health Department,
Indianola, Miss.

This letter was referred to Dr. Herrmann who replies:

*To the Editor:*—Dr. Labecki is right. He read the paper more carefully than I or my associates read the proof. The statement on page 509 concerning the direct application of the Fick principle should read, "cardiac output per minute equals the total oxygen consumption divided by the arteriovenous oxygen difference times 100." The only way I can explain it is that I had "A.V." in my manuscript and my secretary interpreted the A.V. incorrectly as auricular-ventricular rather than as it should have been, arteriovenous. I should have caught the error in proofreading.

The routine application of the Fick principle in measuring the cardiac output in man has been indirect. However, right heart catheterization permits the direct application in man. There is some preference for determination of the difference between oxygen content rather than carbon dioxide content in the arterial and venous blood samples. The arterial blood is taken from the femoral artery under oil. The venous blood is drawn from the right atrium by venous catheter. Catheterization has thus facilitated the collection of samples of truly mixed venous blood from man which could previously be obtained only by puncturing the right side of the heart. This was done in animals, which of course, was not justifiable in human beings, because the risk was too great. However, the dangers with the present method are practically nil. Heart catheterization has made possible the application of the direct Fick principle to human beings.

George R. Herrmann, M.D.,
Professor of Internal Medicine, Galveston, Texas.

# Medical Examinations and Licensure

## COMING EXAMINATIONS AND MEETINGS

### NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: *Parts I and II.* Various Centers. Sept. 12-14. Exec. Sec., Mr. E. S. Elwood, 225 S. 15th St., Philadelphia 2.

### EXAMINING BOARDS IN SPECIALTIES

American Board of Anesthesiology, Inc. *Oral.* Denver, Oct. 16-20. Sec., Dr. Curtiss B. Hickcox, 745 Fifth Ave., New York 27.

American Board of Dermatology and Syphilology, Inc.: *Written.* Various Centers, Sept. 15. *Oral.* Cincinnati, Sept. 15. Sec., Dr. George M. Lewis, 66 East 66th St., New York 21.

American Board of Internal Medicine: *Written.* Oct. 17. Asst. Sec.-Treas. Dr. W. A. Werrell, 1 Main St., Madison 3, Wis.

American Board of Neurological Surgery: *Oral.* Chicago, June 3. Final date for filing applications is Jan. 1. Sec., Dr. W. J. German, 789 Howard Ave., New Haven.

American Board of Obstetrics and Gynecology, Inc. *Part I.* Various Centers. Feb. 3. Final date for filing application is Nov. 5. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh.

American Board of Ophthalmology: St. Louis, Oct. 15-19; Boston, December. Sec., Dr. S. J. Beach, 56 Ivie Rd., Cape Cottage, Maine.

American Board of Orthopaedic Surgery. *Part II,* New York City, Feb. 9-10. Final date for filing application for Part II is Aug. 15. Address: Sec.-Treas., Dr. Harold A. Sofield, Room 1856, 122 S. Michigan Ave., Chicago.

American Board of Otolaryngology: Chicago, Oct. 4-7. Sec., Dr. D. M. Lierle, University Hospitals, Iowa City.

American Board of Pathology: Chicago, Oct. 7-8. Final date for filing application is Sept. 1. Sec., Dr. Robert A. Moore, 507 Euclid Ave., St. Louis.

American Board of Pediatrics: *Oral.* Cleveland, Sept. 16-18; New York City, Oct. 21-23; Chicago, Dec. 9-11. Sec., Dr. John McK. Mitchell, 6 Cushman Road, Rosemont, Pa.

American Board of Plastic Surgery: Examinations are given in June and November of each year in the home town of applicants. Sec.-Treas., Dr. Louis T. Byars, 400 Metropolitan Bldg., St. Louis, Mo.

American Board of Preventive Medicine and Public Health: *Parts I and II.* New York, Oct. 22-24. Final date for filing application is July 22. Sec., Dr. Ernest L. Stebbins, 615 N. Wolfe St., Baltimore.

American Board of Psychiatry and Neurology, Inc. *Special Examination.* Chicago, Oct. 24-25. December, New York City. Final date for filing applications is Sept. 15. Sec., Dr. F. J. Braceland, 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Radiology: *Oral.* Cincinnati, Sept. 28-Oct. 2. Sec., Dr. B. R. Kirklin, 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Surgery: *Written.* Various Centers, October 26. Sec., Dr. J. Stewart Rodman, 225 S. 15th St., Philadelphia.

American Board of Urology: *Written.* December. *Oral and Clinical.* Chicago, Feb. 11-15. Final date for receipt of case histories is Sept. 1, 1949. Sec., Dr. Harry Culver, 7935 Sunnyside Road, Minneapolis 18.

### BOARDS OF MEDICAL EXAMINERS

Alaska:* Juneau, Sept. 6. Sec., Dr. W. M. Whitehead, Box 140, Juneau.

Alabama: *Examination.* Montgomery, June 27-29. Sec., Dr. D. G. Gill, 519 Dexter Avenue, Montgomery.

Arkansas:* *Examination.* Little Rock, Nov. 3-4. Sec., Dr. Joe Verser, Harrisburg. *Eclectic.* Little Rock, Nov. 3. Sec., Dr. Clarence H. Young, 1415 Main St., Little Rock.

California: *Examination.* Los Angeles, Aug. 15-18. Sec., Dr. Frederick N. Scatena, 1020 N Street, Sacramento.

District of Columbia:* *Examination.* Washington, Nov. 14-15. Sec., Dr. G. C. Ruhland, 4130 E. Municipal Bldg., Washington.

Florida: *Examination.* Jacksonville, Nov. 27-29. Sec., Dr. Frank D. Gray, 12 N. Rosalind Ave., Orlando.

Georgia: *Examination.* Atlanta, Oct. 11-12. *Reciprocity.* Atlanta, Oct. 13. Sec., Mr. R. C. Coleman, 111 State Capitol, Atlanta 3.

Guam: *Endorsement.* Agana, Last Friday of each month. Sec., Capt. C. K. Youngkin, Dept. of Public Health, Guam, % F.P.O., San Francisco.

Illinois: Chicago, Oct. 4-6. Supt. of Registration, Mr. Fred W. Ruegg, Capitol Bldg., Springfield.

Indiana: *Examination.* Indianapolis, June. Sec., Dr. Paul R. Tindall, 1138 K. of P. Bldg., Indianapolis.

Iowa: *Examination.* Des Moines, Dec. 5-7. *Reciprocity.* Des Moines, Sept. 5, Oct. 3, Nov. 7, Dec. 5. Sec., Dr. M. A. Royal, 506 Fleming Bldg., Des Moines.

Kansas: Topeka, Dec. 8-9. Sec., Dr. J. F. Hassig, 905 N. Seventh St., Kansas City.

Maryland: *Examination.* Baltimore, Dec. 13-16. Sec., Dr. Lewis P. Gundry, 1215 Cathedral St., Baltimore 1. *Homeopathic. Examination.* Baltimore, Dec. 13-14. Sec., Dr. John A. Evans, 612 West 40th St., Baltimore.

Minnesota:* Oct. 18-19. Sec., Dr. Julian F. Du Bois, 230 Lowry Medical Arts Bldg., St. Paul 2.

Mississippi: *Reciprocity.* Jackson, December. Sec., Dr. Felix J. Underwood, State Board of Health, Jackson 113.

Montana: Helena, Oct. 3-5. Sec., Dr. Otto G. Klein, First National Bank Bldg., Helena.

Nevada: Carson City, Nov. 7. Sec., Dr. George H. Ross, 112 N. Curry St., Carson City.

New Hampshire: Concord, Sept. 8-9. Sec., Dr. J. S. Wheeler, 107 State House, Concord.

New Jersey: Oct. 18-21. Sec., Dr. E. S. Hallinger, 28 W. State St., Trenton.

New Mexico:* Santa Fe, Oct. 10-11. Sec., Dr. Charles J. McGoey, Coronado Bldg., Santa Fe.

New York: *Examination.* New York, Albany, Syracuse and Buffalo, Oct. 4-7. Sec., Dr. Jacob L. Lochner Jr., 23 S. Pearl St., Albany 7.

Ohio: *Examination.* Columbus, December. *Endorsement.* Oct. 2. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

Puerto Rico: San Juan, Sept. 6-10. Sec., Dr. Luis Cueto Coll, Box 3717, Santurce.

South Carolina: *Examination.* Columbia, Nov. 8-9. *Reciprocity.* First Monday of every month. Sec., Dr. N. B. Heyward, 1329 Blanding St., Columbia.

Tennessee: *Examination.* Memphis, Sept. 28-29. Sec., Dr. H. W. Qualls, 1635 Exchange Bldg., Memphis 3.

Virginia: *Examination.* Richmond, Dec. 2-3. *Reciprocity.* Richmond, Dec. 1. Sec., Dr. K. D. Graves, 631 First St., S.W., Roanoke.

Wisconsin:* *Examination.* Madison, Jan. 10-12. Sec., Dr. C. A. Dawson, River Falls.

## MEDICAL ECONOMIC REVIEWS AND ABSTRACTS

### Prepared by the Staff of the Bureau of Medical Economic Research

*(Continued from page 1117)*

**Old Age and Survivors' Insurance and Old Age Assistance in the South.** By E. J. Eberling. The South. Econ. J. 15:54-66 (July) 1948.

Based on payroll taxation to which employer and employee jointly contribute, the Old Age and Survivors' Insurance has as its greatest defect the limitation of coverage. As it excludes agricultural, domestic and self-employed workers, among others, it does not cover 46 per cent of the working groups. This amounts to discrimination against the South, the author maintains, because this section is largely agricultural. In spite of lower state incomes for provision of public assistance, it throws on these states a heavier financial burden than that borne by states with higher incomes. In turn, this increases the expenditures for the noncontributory Old Age Assistance in the South, although the original intent of the act was to decrease the Old Age Assistance slowly as payroll deductions placed an increasing number under the Old Age and Survivors' Insurance. Thus, while the Old Age Assistance number rose from 205 per thousand in June 1946 to 222 in July 1947 for the entire country, the number in the South rose from 235 to 284, showing that the other states were actually following the operation of the plan as hoped for at its institution. This increase in the Old Age Assistance is also undesirable because the noncontributary plan does not grant the same opportunities for retention of self respect and pride as the payroll deduction plan. A further result of the extended use of Old Age Assistance is the lowering of benefits to a mere pittance in many states of the South and even denial in some instances of eligible needy because of lack of funds.

In addition to the limitation of coverage by the Old Age Survivors' Insurance and its resulting complications, the benefits secured under it are inadequate in the South. Not only have the living costs there risen faster than benefit increases—a fact true throughout the nation—but the greater the number of beneficiaries of Old Age Survivors' Insurance, the lower the per capita income.

In agreement with the unheeded 1946 recommendation of the House Ways and Means Committee, Eberling calls for all-inclusive coverage under the Old Age Survivors' Insurance, contending that administrative difficulties long recognized are not insurmountable. To tide over the needy during delay in this change, he suggests federal grants to the South for public assistance, allocated on the basis of per capita income, the lower income state receiving the most aid.

More generally, the author points out the need for revision of benefits to meet the cost of living, the need for a lowered age of eligibility in the cases of women to 60, because women are usually younger than their husbands, and the need for an addition of disability insurance to the Old Age Survivors' Insurance.

**Relationship Between Per Capita Income and Mortality in the Cities of 100,000 or More Population.** By Marion E. Altenderfer, Associate Statistician, United States Public Health Service. Pub. Health Rep. 62: 48 1681-1691 (Nov. 28) 1947.

The United States Public Health Service has undertaken a study of the relationship between health status and environmental factors in all counties of the United States and in cities with 10,000 or more population. This article analyzes mortality data for the ninety-two cities with populations of 100,000 or over in order to answer the questions "What is the relation between the per capita buying income of the community and mortality from several causes?" and "What is the influence of the color composition of the population on this relationship?" Mortality data were obtained from the Bureau of the Census report on births and deaths for the period 1939-1940 and were adjusted to the age distribution of the United States population in 1940. Color composition data and population figures were taken from the 1940 census and per capita buying income statistics were from the "Annual Survey of Buying Power" published by *Sales Management.*

The ninety-two cities were divided into three groups on the basis of per capita income, and the average total, infant and maternal mortality rates were computed for each group. The average total death rate decreased from 1,212 for the lowest income group of cities to 1,097 for the middle group to 1,092 for the highest group. The infant mortality rate showed the same relationship to income, while the maternal mortality rate in the middle group was considerably lower than in the lowest group and also slightly lower than in the highest group. Average mortality rates for seventeen major diagnosis groups were computed for each of the three income groups of cities. The rates for syphilis, chronic diseases, influenza and pneumonia, appendicitis and hernia showed the same trend as total and infant mortality rates, while the rates for infectious diseases, tuberculosis, pellagra, diseases of the ear, nose and throat, and accidents other than motor vehicle accidents, cancer, cirrhosis of the liver and diseases of the gallbladder tended to increase with increased income, but the rates for diabetes and ulcer of the stomach showed no correlation with income.

In order to examine the relationship between color composition and mortality, the ninety-two cities were divided into three groups according to the percentages of white persons in the population. The group of cities with less than 90 per cent of white persons had the highest average total, infant and maternal mortality rates, while the group with 97 per cent or more of white persons had the lowest rates. A further division of the three income groups into the three color composition groups reveals the effect of this relationship between color composition and mortality on the relationship between income and mortality. With the addition of the color factor, the inverse relationship between mortality and income holds true in all but three cases; the lowest total death rate is found in the middle income group in cities with 90 to 96.9 per cent of white persons, and the lowest maternal mortality rate occurs in the middle income group in the two groups of cities with less than 97 per cent white populations. At each income level, mortality rates vary inversely with the proportion of white persons in the population. For the five disease categories (infectious, tuberculosis, syphilis, pellagra, and influenza and pneumonia) for which national nonwhite mortality rates are general higher than white rates, mortality is greatest in cities with the largest nonwhite population; the reverse is true of the four diagnoses (cancer, diabetes, goiter and gallbladder diseases) in which white rates exceed nonwhite rates. In general, the color composition of the population does not seem to affect the pattern of association between income and mortality from the seventeen diagnoses; the color differential was most prominent in the cases of exophthalmic goiter, gallbladder diseases and diabetes.

Caution should be used in drawing conclusions from the observed relationships between income and mortality rates. Low income may be the effect, as well as the cause, of ill health. Moreover, it is difficult to isolate the effects of differences of income on mortality rates from the effects of social and cultural differences such as housing, education, diet preferences, hygienic habits and willingness to make use of medical care facilities. The lower infant mortality rates in upper income groups are no doubt largely because of lower birth rates, better health education and better care of infants among higher income families. The causes of death which are positively correlated with income characteristically occur later in life than do those diseases showing a negative correlation with income. Since per capita buying power is probably greater for older persons, the observed relation between income and mortality from specific causes may be due primarily to failure to use age-specific rates in the computations. The inverse ratio between mortality and the proportion of white persons within each income group indicates that the association between mortality and color composition is due to differences in ways of life as well as to variations in income. Altogether, the data presented in the article would seem to prove the wisdom of a statement from the Brookings report on compulsory health insurance: " . . . health problems in the United States involve economic, cultural, and social racial differences and interracial relations."

**Statistical Problems in Developing Voluntary Medical Expense Insurance Plans.** By Morton D. Miller, The Equitable Life Assurance Society of the United States. J. Am. Statistical Assoc. 43: 290-299 (June) 1948.

Since 1930 the number of persons covered by hospitalization insurance has risen from almost nothing to 52,000,000. The spread of voluntary insurance plans to insure the cost of physicians' services has been even more phenomenal. Only since 1938 has the cost of surgical operations and of obstetric care been included in insurance plans; since 1943 the cost of other types of medical services has been included; yet, in 1947 over 20,000,000 persons were insured for some surgical benefits, of whom one third were also covered by some form of medical expense insurance for nonsurgical services.

While community organizations similar to and sometimes affiliated with the Blue Cross hospital service associations have participated in the development of medical care insurance, most of the coverage has been provided by the life insurance companies through group insurance (insurance in which a single master contract issued usually to an employer covers the group of his employees and often their wives and children). Cash payment is made in accordance with a schedule of maximum reimbursements in the master policy; any payment in excess of the fees in the schedule are made by the insured employee himself.

These new forms of insurance involve a great number of actuarial and statistical problems. Among these is the one of securing some basis for the establishment of the initial premium rates. The foundations for calculating these rates are frequency of occurrence of the event insured against and the average amount payable when the event occurs. On the basis of experience gained in connection with hospitalization and other forms of insurance, one company computed a scale of premium rates for group surgical insurance. Since the annual rate of hospitalization was found to be 7 per hundred for male employees and three fourths of all hospitalized cases involved surgery, the annual frequency of surgical procedures for male employees would be 5.3 per hundred. After a study of the proposed schedule of benefits, it was estimated that $50 would be the average amount of each claim. The product of the frequency and the average benefit gave $2.65 for the net annual claim cost. This figure, when increased by the amount calculated to be necessary for expenses of operation and contingencies, resulted in a gross monthly premium rate of $0.35 per male employee.

In accordance with experience under other forms of disability insurance, the gross monthly premium rate for a female employee was set at $0.70, double that for a male employee. In practice, separate premium rates were not charged for male and female employees but a composite rate was computed at the effective date of the group policy depending on the percentage of female employees covered. The gross monthly premium rate for a dependent family unit (a wife and two children) was $1.40 if obstetric benefits were excluded and $2 if obstetrics were not excluded.

The construction of initial premium scales for the group medical expense plans involved a much less satisfactory statistical basis than that used for surgical benefits. It was necessary to fall back on studies made of the utilization of medical care by uninsured persons. But such studies did not present an accurate picture, since the very presence of insurance benefits materially affect their utilization. An increase in utilization rates was a usual consequence of a reduction of the cost which would otherwise be a deterrent to the demand for such services.

Group insurance policies are written for a period of one year, subject to annual renewals thereafter. The premium rates are subject to revision upward or downward at the end of each policy year, and the policies participate in the surplus earnings of the company through a declaration of dividends or retroactive rate credits. These dividends or rate credits are computed by a method known as "experience rating," in which weight is given to the claim experience of the individual group policy and to the claim experience of the class of policies to which it belongs. Renewal underwriting and the computation of dividends or rate credits are made from a record showing premiums due and the number and amount of claims incurred for each group policy for each policy year.

These individual group experience records provide the material for further statistical analysis within a company once a plan for medical or hospitalization insurance is under way. The question arises whether there should be established, on a continuing basis, a system of coding individual claims, involving the use of all or a specific fraction of all claims or whether basic claim rates and claim costs should be developed on a continuing basis with any additional detailed information obtained from occasional sample studies designed for specific purposes. The writer believes that the additional detailed information does not warrant the cost of securing it on a continuing basis as against the lesser cost of conducting periodic or occasional sample studies.

It is desirable to pool the experience of several companies not only to improve the reliability of statistical results but to provide a standard by means of which any one company can judge the efficiency of its operations. For this reason a standing committee of the Actuarial Society of America known as the Committee to Prepare Mortality and Morbidity Studies on Group Insurance was established. Since the Committee's work was interrupted by the war, its first study, which is on intercompany morbidity experience, has just been completed for publication in the 1948 *Transactions* of the Actuarial Society. For the present, group medical insurance is not being studied, largely because of the newness of the coverage, the wide variety of plans written and the diversity in policy provisions. The committee has undertaken a sample study based on individual surgical claims to supply information regarding the relative frequency with which different surgical procedures occur and the relative values of the fees being charged by physicians for such procedures.

Although insurance against the cost of medical care is relatively new, there has already been great progress as evidenced by the phenomenal spread of such insurance plans. The statistical studies now being conducted and the experience of the insurance companies will undoubtedly contribute valuable knowledge for continued progress in this field.

**Cooperation for Rural Health.** By Helen L. Johnston, Cooperative Research and Service Division, Miscellaneous Report 123, United States Department of Agriculture, Farm Credit Administration, 1948.

Growing interest in the problems of extending health services among all parts of the population is reflected on all sides. This report presents a broad review of activities among farm groups during the years 1945 to 1947 to solve their own health problems. It is concerned principally with the programs developed by local farmer cooperatives in various parts of the country, but also includes some information on planning activity among national, regional and state farm associations.

Pertinent summaries are given on the history and development of several specific types of programs. Included are cooperative farm group enrolment in Blue Cross hospital plans, the farmer-sponsored Group Health Mutual indemnity hospital-surgical insurance plan and local prepaid cooperative health associations. The report describes the activities of four rural health cooperatives located in Oklahoma, Texas and Kansas which have built their own hospitals and employed physicians and auxiliary staff to provide service to member families. These have been in operation for five to seventeen years.

A final section presents an extensive outline of suggestions for studying, planning and developing rural health improvement programs. This report concerning self-help rural programs will provide interesting perspectives for both urban and rural physicians.

**Factors Influencing the Relative Number of Aged Beneficiaries Under Old-Age and Survivors Insurance and of Old-Age Assistance Recipients in the States.** Federal Security Agency, Social Security Administration, July 1947.

In 1946 the total population over 65 years of age was 10,272,000. There were 1,069,753 beneficiaries of Old Age and Survivors' Insurance, or 104 per thousand aged, and 2,103,536 recipients of old age assistance, or 205 per thousand aged. The ratio between beneficiary and recipient rates was 51:100.

The pattern of the old age assistance program is less well defined than that of the Old Age and Survivors Insurance because of a variation of interpretations of the former by the different states. This factor prevents a consistent relation between beneficiary and recipient rates. However, certain relationships hold in general: (1) a definite positive relation between the covered employment ratio and the beneficiary rate, (2) a positive relation between the beneficiary rate and the degree of industrialization and urbanization, and (3) a positive relation between per capita income and the beneficiary rate and a negative relation between per capita income and the recipient rate.

The beneficiary rate increased from 76 per thousand aged in June 1945 to 104 per thousand aged in June 1946, while the recipient rate increased from 202 to 205 per thousand. In the future, the beneficiary rate should grow to exceed the recipient rate.

There is nothing in the article about the proportion of old age assistance and survivors insurance funds attributed to medical care.

**Forecasts of the Population of the United States, 1945-1975.** By P. K. Whelpton, United States Department of Commerce, Bureau of the Census, 1947. **A revision of Estimates of Future Population of the United States, 1940-2000,** prepared by Warren S. Thompson and P. K. Whelpton for the National Resources Planning Board, 1943.

The forecasting of population trends is exceptionally hazardous because of the control over population size exercised by births, migration and the medical advancements in the conquest of disease. In spite of all the hazards, the Bureau of the Census has realized the importance of obtaining some estimate of the population of United States as far distant as 1975 and has made a commendable attempt to obtain such a forecast.

Mortality rates have been decreasing steadily since 1900. This is true for all age groups, with a greater decline occurring in the younger age groups than in the older. The rates for females have been lower than the rates for males, with both sexes showing a decrease at all ages. Mortality rates for the nonwhite population are considerably higher than for the white, but both decrease at about the same rate. The rate for white males decreased from 66 in 1929-1931 to 46 in 1940-1944 for the under 1 age group, whereas the rate for females decreased from 52 to 35.

Since mortality rates have decreased, life expectancies have increased for both male and female at about the same rate. However, the life expectancies are higher for females than males, and the life expectancies for nonwhites are lower than the life expectancies for whites.

Future trends are estimated on the basis of high, medium and low mortality assumptions. On the basis of each of the assumptions the mortality rates show a definite decline. The infant mortality rates are predicted to be 28 in 1975 for native white males assuming high mortality, 25 assuming medium mortality and 23 assuming low mortality. The trend is similar for females under each of the three assumptions. Decreasing mortality rates tend to increase the length of life; the life expectancies at birth are predicted to be 66, 68 and 71 respectively for the assumptions mentioned.

Since the birth rate depends more on individual behavior, whereas the death rate is influenced by medical changes, the birth rate fluctuates more widely than the mortality rate. Birth rates have decreased at all ages, but the decline was not as great for the younger age groups.

Many forecasts of the future population of the United States have been made; most of the estimates have been too low. Louis I. Dublin, of the Metropolitan Life Insurance Company, in 1931 estimated that the population would be 148,000,000 by the year 1970, and it has already reached 143,000,000 in 1947. Many others have erred in predicting too low a figure, the notable exceptions being Professors Raymond Pearl and Lowell J. Reed of Johns Hopkins University, whose predictions have almost coincided with current population figures. In 1921 they estimated that there would be 149,000,000 by 1950; it now appears that this figure will be approximately realized.

Population trends have been showing a decrease in the relative number of young persons and an increase in the relative number of old persons, and this trend is expected to continue. The population of the United States is aging, as the increasing median age clearly shows. Even though the figures predict an increase in the size of the population when any one of the projections is used, the rate of increase is becoming smaller and smaller, and the results seem to point to a stationary or even a declining population.

**Health Services in England.** By R. C. Wofinden. Price, $2.50. Pp. 186. London, Simpkin Marshall, Ltd., 1947.

This essay by Dr. R. C. Wofinden is a well organized and concise presentation of the historical development of public health legislation in England. Its emphasis is on the administration of the laws as they affect the welfare of the people. The author has reached the conclusion that the course of social and health legislation has been guided by the increasingly popular demand that poverty alone should not stand in the way of decent housing, adequate health services and opportunity for advancement. It has been enacted not primarily for the benefit of the existing poor, but for the greatest good for the greatest number. Recognizing that continued sickness leads to inability to work and thus to poverty, the authors of the legislation directed it toward remedying the causes of illness and, recently, toward preventing sickness.

Measures to improve health may spring from several motives. The humanitarian impulse has motivated many needed reforms. The state has an interest in the preservation of the health of the people. War has often been the spur to research, improved technics and more efficient use of existing medical facilities.

The author has divided the history into three stages. First, the environment of the people was seen to bear directly on their level of health, and steps were taken to improve paving, lighting, water supplies and working conditions in factories and to protect the quality of food. Secondly, infectious diseases were brought under control by isolation, education of the people in cleanliness and nutrition, biologic experimentation and mass immunization. Thirdly, it was recognized that preventive medicine was essential to raise the general level of health. The overload on doctors who are pressed for time to give adequate treatment, let alone for preventive work, coupled with ignorance and apathy on the part of many who could be helped, has rendered progress in preventive medicine difficult.

Dr. Wofinden's approach to the history of public health legislation is to list specific measures passed by Parliament, discuss important provisions of the laws and relate each act to conditions existing in the country and to earlier laws. As previously stated, his emphasis is on the administrative procedure employed under each law. He thereby demonstrates clearly that the way in which a system is devised, the people who operate it and the agencies it uses to carry out its policies govern the effectiveness of public health measures.

The original essay was written in 1946 and has been made as complete as possible by the postscript containing the recent health act. In the small and readable volume Dr. Wofinden has surveyed the history of public health in England and has established some criteria for evaluating public health services.

---

# Medical Motion Pictures

## FILM REVIEWS

**The Doctor.** 16 mm., black and white, sound, 400 feet, showing time ten minutes. Prepared in collaboration with Louis W. Sauer, M.D., Northwestern University Medical School, Chicago. Produced in 1947 by and procurable on rental or purchase from Encyclopedia Britannica Films, Inc., 1150 Wilmette Avenue, Wilmette, Ill.

This motion picture depicts the role of a pediatrician in his office, at the hospital and at the home of a patient. He is shown, assisted by his office nurse, performing a routine physical examination of a young boy and vaccinating a baby for smallpox. The film then shows him making his rounds in the hospital, visiting his patients to determine the progress of each. Finally he visits a patient in a private home, at which time he makes an examination for diagnosis, prescribes for the patient and gives the mother instructions as to care.

The film also illustrates the use of such instruments as the stethoscope and blood pressure apparatus and shows how the doctor interprets the results of the roentgen examination in the diagnosis of a fracture. Other illustrations are presented which would aid in acquainting the child with the activities of a doctor in such a way as to eliminate any fear a child may have when medical care is necessitated.

In the part showing the doctor taking the temperature of a child with measles, an error in technic was noted. The doctor took the thermometer out of his bag, laid it on the bed of the patient and then inserted it in the patient's mouth. After the thermometer was withdrawn from the patient's mouth, it was replaced in its container immediately without being sterilized.

The film is suitable for showing to children in the elementary school level.

The photography and narration are excellent.

**Skin Antiseptics, Evaluation of Effectiveness of Some Widely Employed Antiseptics.** 16 mm., black and white, sound, 1,125 feet (1 reel), showing time twenty-eight minutes. Produced in 1948 by Audio Productions, Inc., New York. Procurable on loan from Iodine Educational Bureau, Inc., 120 Broadway, New York 5.

The efficiency of iodine as an antiseptic agent for preoperative preparation of the skin is compared with organic mercurial compounds. The results and calculated dilution values of numerous in vitro tests of several commonly used antiseptics are presented. In the phenol coefficient test, an antiseptic is simultaneously tested and compared with phenol under identical conditions against standard test bacteria Staphylococcus aureus and Salmonella typhosa. The weakest dilution of the antiseptic which will kill the standard test culture is ascertained by mixing certain proportions of the various dilutions of antiseptic with a broth culture of the test organism and allowing the mixture to stand for varying periods of time at a designated temperature. At specified intervals, portions of the mixture are transferred to tubes containing broth and incubated for forty-eight hours. Bacteriostasis is differentiated from bactericidal action by subculturing in a medium containing a neutralizing agent. The effective dilutions of an antiseptic against the micro-organism are revealed in the tubes in which no bacterial growth occurs. The detrimental effect of organic matter (blood serum) on the activity of all antiseptic agents is shown but is inadequately stressed. An in vivo technic incorporating intraperitoneal implantation of treated and untreated mouse tails is given. In the final analysis topical application on human skin is demonstrated and the efficacy of the agents determined by scraping with sterile knife blades which are subsequently cultured in broth.

Toxicity tests are shown in which chick embryos and skins of rabbits and guinea pigs were utilized. Histologic sections show that the antiseptics were nonirritating. The authors correctly emphasize that no single test yields consistently accurate results.

With practically no exceptions, iodine is shown to have more bactericidal effect than any of the other agents. The efficiency of soap and water cleansing is minimized. One error in technic occurs in demonstrating the agar-cup plate method in that, after the plug of agar is cut out of the medium, the cup is not sealed with a small amount of melted agar before the antiseptic is added.

The usefulness of this film is somewhat limited. It would be of interest as a summary for a series of lectures on bacteriologic technics or to surgeons who are particularly interested in skin asepsis. Several titles are superimposed over the background of periodicals and bottles. Some of these titles are difficult to read because they blend in with the background. Otherwise, the photography and narration are excellent. The photomicrographs illustrating the results of various tests and the split frame technic are especially impressive.

**Getting Ready for the Dentist.** 16 mm., black and white, sound, 325 feet, showing time ten minutes. Prepared in 1947 by Alice V. Kelliher, Ph.D., with the cooperation of Dr. Arthur A. Friend, New York University. Procurable on rental from New York University Film Library, 26 Washington Place, New York 3, or on purchase from Willow Distributing Co., Inc., 551 Fifth Avenue, New York 16.

This film shows how a child of 3 years may be prepared for a visit to the dentist through the thoughtful cooperation of parents and the dentist. Through a visit to the dentist to watch Mother have a roentgenogram, the small girl becomes acquainted with the equipment used there. At home Mother and Father play "dentist" with her until the steps in roentgen examination become part of her familiar everyday experience. She returns to the dentist's office for her own roentgenogram and goes through the experience with a minimal amount of disturbance.

The authors are to be commended on the gravity of the small child who plays "Helen"; it is much more reassuring to parents to see a grave, somewhat timid child responding to this type of treatment.

Much emphasis is placed on the adjustment of a child to roentgen examination of the teeth.

This motion picture should interest Parent-Teachers Association and child guidance groups.

The photography is good, but the narration is poor and the quality of the voice is unsatisfactory. The voice level drops at the end of most sentences.

**Safer Gastrectomy Operative Procedure.** 16 mm., color, sound, 475 feet (1 reel), showing time eleven minutes. Prepared by L. A. Alesen, M.D., F.A.C.S., Los Angeles. Produced in 1946 by Billy Burke Productions, Hollywood. Procurable on loan from the Seal-Ins Laboratories, 2857 East Eleventh Street, Los Angeles 23.

This picture illustrates the use of an Alesen T-tube in conjunction with a subtotal gastrectomy in order to prevent obstruction of the afferent loop of jejunum and to cut down the chances of disruption of the duodenal stump. The technic of doing a subtotal gastrectomy is well shown on a cadaver, and toward the end of the film certain pertinent points in the use of the Alesen T-tube are shown in an actual operative procedure.

The film is satisfactory for the purpose for which it is designed and may be of use in safeguarding against disruption of the duodenal stump by prevention of kinking of the afferent loop. The tube is sterilized in a benzalkonium chloride solution 1 to 1,000 for 15 minutes at room temperature and disintegrates in about 96 hours. Serial roentgenograms are shown to illustrate the disintegration.

From a technical point of view, if the film is used in conjunction with a lecture or conference on gastrectomy, it would be satisfactory for showing to general surgeons, medical students, interns and residents.

The surgical technic as illustrated is good. The photography is excellent.

**Diseases of the Gallbladder.** A Photographic Supplement for Lectures or Conferences. 16 mm., color, silent, 400 feet, showing time sixteen minutes. Prepared in 1949 by Hilger Perry Jenkins, M.D.; Rudolph Janda, M.D., and Douglas Packard, M.D., Department of Surgery, University of Illinois, College of Medicine, and Woodlawn Hospital, Chicago. Procurable on loan from Hilger Perry Jenkins, M.D., 826 East Sixty-First Street, Woodlawn Clinic Building, Chicago 37.

This motion picture illustrates cases with various pathologic conditions of the gallbladder. Pertinent facts in the case histories are presented, and the roentgenographic observations are well demonstrated. An attempt is not made to show the complete story as to causation, diagnosis, treatment, prognosis, complications and the like. The picture shows the nature of the condition as seen at the operating table or in the pathologic laboratory.

This film can be recommended as an adjunct to a lecture or conference on gallbladder diseases to general surgeons, residents, interns and medical students. The film is well captioned and the photography is good.

**Let's Look at Water.** 16 mm., black and white, sound, 776 feet (1 reel), showing time twenty minutes. Produced in 1947 by the National Film Board for the Department of National Health and Welfare, Ottawa. Procurable on rental or purchase from the National Film Board of Canada, 620 Fifth Avenue, New York 20 and 400 West Madison Street, Chicago 6.

This motion picture illustrates the functions of a water purification system. It shows how water serves all forms of life, demonstrating ways water can be contaminated and how water may be a source of disease. There seems to be much extraneous material in the film, which includes a considerable amount of stock footage on India and China and several close-ups of still pictures. A little judicious editing would improve the picture. This is an excellent informational film to be used for adult study groups, high school and college students studying water purification. It could not be used effectively in such groups as parent-teachers' association and women's clubs, since it is technical in sections, and some of the procedures are not applicable in the United States. The photography and narration are good.

**Manson's Blood Fluke.** 16 mm., black and white, sound, 592 feet (1 reel), showing time nineteen minutes. Produced in 1948 by and procurable on loan from the Federal Security Agency Public Health Service, Communicable Disease Center, 605 Volunteer Building, Atlanta 3.

This motion picture depicts in detail the life cycle of the parasitic blood fluke Schistosoma mansoni. It shows the ciliated miracidia hatching from spined eggs and penetrating certain Planorbid snails. Within the snail each miracidium becomes a primary sporocyst. Germ cells of the primary sporocyst grow into secondary sporocysts, which in turn produce thousands of cercariae. The cercariae escape from the snail into the water. The mode of infection is clearly presented by showing the parasites penetrating human skins, migrating through the blood vessels to the lungs and traveling to the portal veins of the liver, where they reach maturity. The adult worms live in the mesenteric veins of the colon, feed on blood and lay eggs within the blood vessels. Some of the ova escape through the bowel mucosa into the fecal mass, while others remain in the bowel wall and cause scarring and others migrate to the lungs from the hemorrhoidal veins and cause fibrosis. Clinical cases are shown in their native environment. In 1 case, the patient is followed to the postmortem table. The film ends with a recapitulation of the major concepts which serves to unify the whole. The geographic distribution of this infection is not mentioned. It is really needed to complete the picture. This is an excellent teaching film for general practitioners, parasitologists, postgraduate students and medical students. The photography and animation are well done.

## AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1938 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Phosphatases in Blood of Man: Values in Whole Blood, Plasma, Cytolysates and Erythrocytic Suspensions. H. Behrendt.—p. 167.

**Aminopterin® in Leukemia.**—Meyer and his associates report observations on 43 patients with leukemia, who were treated with aminopterin® (4-aminopteroylglutamic acid). Only 4 patients showed improvement in hematologic and clinical pictures. The 4 improved patients were children; 3 had leukemia of the acute lymphoid type and 1 of the acute myeloid type. Of the other 39 patients, 15 showed toxic effects of the drug, necessitating discontinuance of treatment, and in the remaining 24 the clinical course was unaffected. Beneficial and toxic effects could not be related to dosage according to weight or to the simultaneous administration of liver extract or teropterin® (sodium pteroyl triglutamate). The unpredictable action of aminopterin® and its evident toxicity indicate that this drug will have limited use in the treatment of leukemia. Other related less toxic compounds may be of greater value.

**A Folic Acid Antagonist in Chronic Leukemia.**—This study by Berman and co-workers is based on observations of the effect of the folic acid antagonist aminopterin® (4-aminopteroylglutamic acid) in 9 patients with chronic leukemia. One of the patients with myelogenous leukemia received two series of treatments. The drug was taken orally in daily doses ranging from 1.25 to 7.5 mg. over periods of six to twenty-five days. Stem cells, granulocytes and immature lymphocytes decreased in number during treatment, but mature lymphocytes were relatively unaffected. There was no regular effect on the erythrocyte and platelet counts. There was a disturbance of erythropoiesis characterized by the appearance of megaloblasts in the marrow of treated patients, reflecting folic acid deficiency produced by the use of the folic acid antagonist. Although 4-aminopteroylglutamic acid has a definite hematologic effect, there was no subjective improvement in any of the patients. The use of the drug in chronic leukemia is limited by the early development of toxic phenomena.

**Psychosurgery.**—Freeman mentions some of the newer psychosurgical operations and discusses the considerations that should influence the psychiatrist in his choice of operation. The mortality rate and the incidence of convulsive seizures have to be considered. Prefrontal lobotomy has a fatality rate in the neighborhood of 3 per cent. The open operation in the hands of skilled surgeons like Love and Poppen has seen a reduction below 2 per cent. No fatalities have followed topectomy and only one in a series of more than 200 transorbital lobotomies. Operative mortality statistics with regard to other operations are not adequate because of the small number of cases. Convulsive seizures follow any injury to the brain in a certain percentage of cases. In lobotomy the liability to convulsions is directly proportional to the amount of damage. Convulsions are not necessarily disabling, and they tend to disappear in the course of time and with medicinal treatment, but they are embarrassing to the surgeon and distressing to the families of patients. Incidence of convulsive seizures cannot be adequately estimated until some five years have elapsed after operation.

**Massive Hematemesis; Analysis of 300 Cases.**—Costello says that in the management of massive hematemesis one encounters a divergence of opinion as to whether treatment should be medical or surgical. Other problems in therapy include those concerning the advisability of using gastric siphonage, oral feeding, blood transfusions and sedation. The author studied 300 patients who had had massive hematemesis. Chronic duodenal ulcer accounted for 171 of the 300 patients with massive hematemesis. Acute gastritis, chronic gastric ulcer, ruptured esophageal varix, chronic gastritis and gastric carcinoma were the causes in other patients. Of the 75 patients who died, 71 had not received adequate blood replacement. Therapy should primarily be directed not toward surgical closure of the injured vessel, which natural processes often will close spontaneously, but toward support of the depleted blood volume. The theory that restoring blood pressure risks "blowing out" a forming thrombus has no scientific proof. During the past two years, 73 patients were treated by prompt blood replacement. Operative intervention was not undertaken. Feeding varied between the Meulengracht diet, the Sippy diet, liquid diet and protein dextrimaltose ("predigested") liquids. Only 4 per cent of this group of 73 patients died as compared with 25 in the 300. The author recommends the following plan for the treatment of massive hematemesis during the actively bleeding stage: (1) careful determination of blood needs by the copper sulfate falling drop method repeated frequently; (2) complete restoration of blood as promptly as possible; (3) oral administration of predigested protein-carbohydrate-vitamin mixture, and (4) adequate sedation. After control of hemorrhage and the restoration of nutrient and blood essentials, the advisability of elective surgical intervention may be determined more easily. The authors advise against surgery, indwelling stomach tube with constant suction, gastric lavage and active diagnostic studies during the bleeding stage because these measures were shown to increase mortality.

**Management of Bleeding Duodenal Ulcers.**—According to Fraser and West, opinions are changing with regard to the urgency of immediate surgical intervention in bleeding duodenal ulcers. They reviewed the records of 177 patients with severe bleeding from duodenal ulcers. The diagnosis was established by roentgenography, operation, or, in the fatal cases, by necropsy. The criteria of severe bleeding were a drop in hemoglobin to 65 per cent or less and a reduction in red cells to 3,500,000, or less. One hundred and eight of these patients had a hemoglobin level of less than 50 per cent and a red cell count of less than 2,500,000. Among the 177 cases there were 11 deaths, a mortality rate of 6.2 per cent. One hundred and sixty-five patients were treated by nonoperative measures with 7 fatalities, a mortality rate of 4.2 per cent. Twelve patients did not show a satisfactory response to conservative treatment, and all were operated on in the late period; that is, after more than forty-eight hours of rapid blood loss. Four of these died, a mortality rate of 33.3 per cent. The authors cite figures which indicate that age is of some importance in estimating the chance of survival of a patient under conservative treatment. Of patients beyond 50 years of age who died of hemorrhage, the advent of the bleeding phase of the ulcer generally was accompanied by additional pathologic conditions which contributed materially to the ultimate demise. Arteriosclerosis appeared to be one of the most important contributary causes of death.

**Chemosurgical Treatment of Tumors of Parotid Gland.**—Mohs stresses that in the treatment of tumors of the parotid gland complete removal of the neoplasm must be combined with the preservation of as much as possible of the facial nerve, which traverses the parotid gland. The attainment of these goals is facilitated by the use of the chemosurgical technic. Application of this method in the treatment of cancer of the lip, nose, ear, eyelid, face, extremities, trunk and skin has been described earlier. The author reports a man, aged 80, with a deep-seated mass just below the ear. Premedication with 0.015 Gm. of morphine sulfate was followed in his case by application of the keratolytic dichloracetic acid. Whitening of the skin indicated when the keratin layer had been penetrated. The zinc chloride fixative paste was then applied in a thickness of about 3 mm. The paste contained stibnite (80 mesh sieve), 40 Gm., powdered sanguinaria, 10 Gm., and saturated solution of zinc chloride, 34.5 cc. The treated area was covered with cotton and a moisture-tight closure. After twenty-four hours a layer about 1 cm. thick was excised. There was no pain or bleeding, because the incision was made through killed and fixed tissue. Frozen sections revealed the presence of squamous cell carcinoma with grade 3 malignancy. During the next four days the tumor mass was removed in successive layers. On the fifth day it became impossible to differentiate grossly between normal and cancerous tissues. The layers of tissue from the areas in question were divided into specimens of convenient size; frozen sections were cut and scanned under the microscope and the areas of cancer were marked on a map corresponding to a map drawn on the lesion. Reapplication of the fixative was then limited to the areas demonstrated to be cancerous. This process was repeated daily until the twentieth day, when the removal of the last extension of the cancer was completed. In some areas the microscopically visualized extensions of the neoplasm extended more than 2 cm. beyond the grossly visible portion. One extension followed the perineural lymphatics of the auriculotemporal nerve, while another followed the perimesium of the stylohyoid muscle. Without the systematic microscopic control afforded by the chemosurgical method these extensions would have been missed. On return for checkup two months later the lesion had completely healed with a fine linear scar. The patient was free of cancer when last seen seven years later. Despite the extensiveness of the lesion there was no facial nerve paralysis except for the unimportant mandibular branch. Thirteen of the 17 patients treated by this method had carcinoma and 4 had benign mixed tumors of the parotid gland. The rate of cure in the patients with carcinoma was 60 per cent in the five year period of observation. All of the patients with benign mixed tumor of the parotid gland were successfully treated.

**Clinical Experience with Nitrogen Mustard.**—The Veterans Administration Hospital, West Los Angeles, Calif., has been designated as a center for the treatment of tumors. This provided a relatively large number of patients with leukemia and lymphoma. Goldman and co-workers treated 40 male patients with Hodgkin's disease, lymphosarcoma, leukemia and related diseases with bis-beta-chloro-ethyl-amine hydrochloride (nitrogen mustard). The results obtained are similar to those reported in the literature. Nitrogen mustard appears to be an effective drug in the treatment of Hodgkin's disease, and in some cases of lymphosarcoma, leukemia, mycosis fungoides and polycythemia vera. It appears to offer symptomatic relief in some instances of terminal and metastatic carcinoma of diverse origin. The therapeutic application of the drug results in a prompt response which is more rapid than that which occurs after roentgen therapy, but the remission produced is of much shorter duration.

**Association of Hepatic Insufficiency with Chronic Ulcerative Colitis.**—Pollard and Block say that study of hepatic function in patients with chronic idiopathic ulcerative colitis by means of the bromsulfalein test, cephalin-cholesterol flocculation test, prothrombin time and serum protein revealed the presence of hepatic insufficiency in approximately 50 per cent of the 70 cases investigated. The bromsulfalein and cephalin-cholesterol flocculation tests appeared the most satisfactory indicators of hepatic insufficiency. In 11 of 17 cases of chronic ulcerative colitis studied post mortem, there was histologic evidence of a hepatic pathologic process. Degenerative fatty infiltration was most common, but definite cirrhosis was present in 2 instances. Four cases of cirrhosis of the liver associated with chronic ulcerative colitis are reported. In 2 instances the cirrhosis had its onset prior to the colitis and was probably not related etiologically to the latter. In the other 2 cases the cirrhosis had its onset after the colitis. Evidence is presented to indicate that hepatic insufficiency in association with ulcerative colitis probably has its origin in fatty changes in the liver that occur as a consequence of severe malnutrition or toxemia or both.

- Meningosarcoma with Pulmonary Metastasis: Report of Case. A. J. Swingle.—p. 65.

**Cerebral Blast Concussion.**—Cramer and co-workers state that trauma to the cerebrum comprehended by the term "cerebral blast concussion" may vary from true "commotio cerebri" to multiple petechial hemorrhages of the brain or to actual contusion. The term "blast" refers to the wave of intensely positive pressure produced by a high explosive, just outside the "zone of brisance," within which everything is disintegrated. Just beyond that zone the blast wave has traumatic effectiveness, but thereafter it becomes merely a sound wave. Most of the cases on which this report is based were those of men evacuated from the front with neuropsychiatric problems. In about half of them the primary diagnosis was "psychoneurosis." The diagnosis of chronic subdural hematoma was suspected in some on the basis of a persistent headache, abnormalities of the reflexes, inequalities of the pupils and, rarely, a shift of the pineal gland to one side of the midline, as seen in roentgenograms. In some cases surgical explorations had ruled out hematoma. A psychiatric approach was used during the early observation in most. In the Zone of the Interior, patients who were suspected of having sustained organic lesions were examined as carefully as though one were searching for cerebral tumor. The authors present a detailed history of one patient who had sustained cerebral concussion from a nearby mortar shell blast. The patient exhibited prolonged unconsciousness, amnesia, post-traumatic headache, dizziness, irritability and intolerance to noises. Death followed three months later of delayed post-traumatic cerebral hemorrhage from an area of post-traumatic encephalomalacia. The authors point out that most of the reports on "blast injury" in the literature deal with injuries to the abdominal and thoracic viscera. In these cases of severe injury, the mental disturbances and the lesions in the brain are often commented on only incidentally. The authors made electroencephalograms on 441 cases in which the clinical diagnosis of "blast concussion" had been made. Unconsciousness had occurred in 329 cases. Bleeding from the ears or nose, rupture of the drum membrane or conjunctival hemorrhages occurred in 77 cases. In 5 cases convulsive seizures followed exposure to blast. The electrocardiograms of the 441 patients who were exposed to blast concussion showed a significantly higher incidence of borderline and abnormal tracings than was found in 140 control subjects. The authors feel that their observations are consonant with the facts reported by others who assert that blast concussion is a definite clinical and pathologic entity.

**Vocalization and Arrest of Speech.**—Penfield and Rasmussen record observations on (1) vocalization as a response to stimulation of the human cerebral cortex and (2) arrest of speech by means of stimulation. They have supplemented these observations by reference to the effect of excision of areas of sensorimotor convolutions in the dominant or the nondominant hemisphere. They gained the impression that there is a zone in the sensorimotor convolutions of each hemisphere in which vocalization, lip movement and tongue movement are represented bilaterally. These areas may be called the word articulation zones. If one zone is removed, the functional activity of the other makes speech possible, although there may be transient anarthria. Evidence indicates the presence of a frontal speech area and a parietal speech area in the dominant hemisphere. The functional integrity of these two areas is essential to the mental processes involved in speaking. These two speech areas might be considered a second motor and a second sensory area corresponding to the sensorimotor zone for lips, tongue and vocalization. But the essential neuronal connections between these second speech areas and the sensorimotor zone are not transcortical, as shown by the fact that the face area, as well as the dominant arm area, can be removed without producing aphasia. Consequently, the essential neuronal connections of the second speech areas must be via subcortical pathways to the sensorimotor word articulation area of the rolandic convolution on both sides.

**Retinoblastoma Cured by Radon Seeds.**—Waldman and Shannon report a patient in whom retinoblastoma had been verified by microscopic and gross study of the enucleated eye. The patient has been treated and observed for twelve years. Retinoblastoma in the remaining eye has been treated, with cure for a period of nine years. Enucleation of the left eye was performed in 1935, when the patient was 18 months of age. The optic nerve was microscopically free of tumor cells. Roentgen rays were given to the right eye. The total of 3,104 r given was far below the dose advised by the fractionated method of Martin and Reese. In November 1938, 2.5 millicuries of radon was applied in dental compound and sewed to the overlying sclera. Five applications of radon seeds were used in a holder from March 1939 to May 1942. The patient was 10 months old when treatment was instituted and is 13½ years old at the time of this report. Typical irradiation cataract and changes in the fundus, probably incidental to radon therapy, are described. Visual acuity is 6/60. The patient attends a sight-saving school. The changes in the lens, and perhaps the macular changes, may become more pronounced. In retrospect, the areas thought to be new growths in April 1942 may have been a late reaction to the radon applied previously.

**Chronic Inflammatory Lesions in Rheumatoid Arthritis.**—Ogryzlo states that in 1945 Freud and associates described small inflammatory nodules in the muscles of amputated lower limbs of a patient with rheumatoid arthritis and substantiated this finding by consistently demonstrating lesions in biopsy specimens from 14 patients with typical rheumatoid arthritis. These authors and others regarded the lesion as specific and essential in rheumatoid arthritis. They considered the associated muscle degeneration as a consequence of the inflammatory lesion. The application of this new finding as an aid to diagnosis was advocated. The present study was undertaken to determine the specificity of the lesion. Sections of skeletal muscle taken routinely during the past ten years in the departments of pathology, surgical pathology and neuropathology of the Toronto General Hospital were reviewed, as well as additional sections obtained in a group of selected cases. The latter were chosen from among cases of disease in which pathologic changes of muscle might be expected to occur. A total of 158 cases were examined. Ogryzlo says that inflammatory lesions of skeletal muscle of the type which have recently been described in patients with rheumatoid arthritis were also found in patients with rheumatoid arthritis, dermatomyositis, periarteritis nodosa, disseminated lupus erythematosus and subacute bacterial endocarditis. Indistinguishable lesions were also encountered in cases of Addison's disease, hyperthyroidism, myasthenia gravis, fascioscapulohumeral atrophy, subacute combined degeneration and peripheral neuritis. The lesions were marked by focal, perivascular or, occasionally, more diffuse collections of cells. The cells were mainly lymphocytes and a few plasma cells. Polymorphonuclear leukocytes, eosinophils and large, pale mononuclear cells were present in varying proportions. The lesions are regarded as nonspecific in character. They showed no constant relationship to the degree of degenerative change present in the muscle.

**Plasma Cell Mastitis.**—According to Halpert and associates plasma cell mastitis was first described in 1931 and later recognized as a pathologic entity. Since then 45 cases have been reported, but in none of them was the disease associated with carcinoma of the mammary gland. In 1947, Gaston reported cases in which the concurrence with carcinoma was mentioned. The authors present 3 patients with plasma cell mastitis and 3 patients with carcinoma of the mammary gland in whom there was cellular reaction with plasma cells predominating about acini and ducts believed to be independent of the carcinoma. Plasma cell mastitis may be redefined as a focal chronic inflammatory process in the mammary gland. Plasma cells are dominant in the inflammatory process and far outnumber all the other cells participating in the reaction. The cause of the lesion is unknown. Multiple areas of fat necrosis often accompany plasma cell mastitis. In the 3 cases of plasma cell mastitis there were areas of fat necrosis; either fat necrosis, or plasma cell mastitis alone, or both in combination form a solid mass, indefinitely delineated, not unlike carcinoma. In the 3 cases of carcinoma of the mammary gland there was a cellular reaction in which plasma cells predominated. The fact that most of the cellular reaction was about the acini and ducts of the mammary gland and in areas distant from the neoplastic involvement favors the view that the plasma cell reaction was independent of the carcinoma. Accurate history may aid in the differential diagnosis. A firm mass appearing in the mammary gland following trauma and persisting for years with no appreciable change in size suggests fat necrosis. A firm mass appearing in the mammary gland without a history of trauma and persisting for years with no appreciable change in size suggests plasma cell mastitis. A sudden increase in the size of either type of mass points toward a combination with carcinoma. The nature of the mass can be determined only by microscopic examination. Radical operation is indicated only in case the mass proves to be cancerous.

**Virus Versus Toxic Hepatic Necrosis.**—Popper and Franklin point out that epidemiologic considerations were primarily responsible for the acceptance of a viral causation of the different forms of hepatitis encountered in the armed forces in World War II. The question arises whether in the civilian population most instances of a similar clinical picture of primary acute hepatitis without known epidemiologic background are of the same, presumably virus, causation. The livers of patients dying of acute primary hepatic necrosis with jaundice in the past nineteen years in a large civilian institution (histologic material was available in 95 out of a total of 136 cases) were compared by the authors with those of a much smaller number of Army personnel. Among 18 of the military specimens 15 revealed various stages of epidemic hepatitis (as described by Luché), whereas 3 revealed a different histologic picture. Among 95 civilian specimens 26 showed changes comparable with those in the majority of the livers from Army personnel, whereas 69 revealed central, peripheral or fatty necrosis. The histories elicited from the patients of the latter group indicated that one fifth had been exposed to substances known to be hepatotoxic. The hepatitis of the former group was considered due to virus, whereas that of the latter was called toxic because it was morphologically similar to the pathologic process observed in man and animals following exposure to substances established as hepatotoxic. The "virus" form, which spreads irregularly throughout the liver, reveals sudden death of the liver cells. The cells break up into small fragments or hyalinize diffusely. This process is associated with an energetic mesenchymal reaction involving chiefly mononuclear phagocytosing cells. In the "toxic" form, in contrast, zonal arrangement is more prominent, the death of cells is gradual and large anuclear cell remnants or fragments are visible, which show shadows of cellular structure; the mesenchymal reaction is subdued, and the inflammatory cells, if present, are often polymorphonuclear; fatty changes are common. The liver is usually larger in the toxic than in the virus form. Renal damage, with azotemia, is greater in the acute toxic than in the acute virus form. In chronic phases of the virus form, "toxic" manifestations may appear in the preserved parenchyma, which may be due to anoxia caused by disturbances of the blood flow. An attempt is made to explain the difference of the morphologic pictures by different mechanisms and speeds of the "virus" and the "toxic" injurious process. Although the term "hepatitis" for these forms of hepatic necrosis appears unsatisfactory from a pathologic standpoint, it may for the time being be retained because of its widespread clinical use.

**Nitrogen Mustards in Leukemia.**—Burchenal and co-workers report their experiences with methyl-bis (beta-chlorethyl) amine ($HN_2$) or with the tris compound ($HN_3$) in the treatment of 38 cases of leukemia. They review 89 cases that have been reported in the literature. The authors also made clinical studies with four other nitrogen mustards, SK 136, SK 137, SK 437 and SK 596. With the possible exception of SK 136 none of these nitrogen mustards had any advantages over $HN_2$. In 54 of the total of 127 cases (38 of their own and 89 from the literature), the disease was chronic myelocytic, in 45 chronic lymphocytic and in 28 acute leukemia. Occasional cases of chronic myelocytic leukemia have responded poorly to some other form of therapy and then responded well to $HN_2$ or SK 136. This is probably due not to a better inherent chemotherapeutic activity of the nitrogen mustards, but rather to the fact that the previously used agent was not, or could not, be pressed to full therapeutic effect, or, as occasionally happens with roentgen therapy, was not localized on the most important focus of the disease. Conversely, some cases responded better to a course of irradiation than to $HN_2$, and it is quite possible that some may also react better to urethane or arsenic. Most patients will probably respond about as well to any of the standard methods of therapy, but patients with disease refractory to one standard technic should be treated by another. The role of the nitrogen mustards in the treatment of chronic lymphocytic leukemia is less clearcut. The responses were much less regular and predictable than in the chronic myelocytic form of the disease. No real beneficial effect can be expected from $HN_2$ or SK 136 in the acute leukemias. In the final analysis, the nitrogen mustards $NH_2$, $NH_3$ and SK 136 are useful adjuncts to the treatment of leukemia, and approximately equal to arsenic, benzene, urethane, radiophosphorus and irradiation. In certain cases, however, there are definite advantages to the use of this method of chemotherapy.

**Cutaneous Nevi and Melanomas.**—Allen applies the term nevus only to the pigmented or nonpigmented lesions composed of melanoblasts, that is, dopa-positive cells containing the enzyme melanogenase. The term is not used in the dermatologic sense of any congenital blemish such as a "vascular nevus" or "sebaceous nevus." The unqualified term melanoma has come to be used interchangeably with malignant melanoma. The nevi include the following: (1) junctional nevus (dermoepidermal nevus or marginal nevus), (2) intradermal nevus (common mole or neuronevus), (3) blue nevus (Jadassohn-Tièche nevus), (4) compound nevus and (5) juvenile melanoma. The junctional nevus is derived from true epidermal cells. The cutaneous malignant melanomas arise from junctional nevi. Hence, malignant melanomas are epidermogenic and should be categorized as carcinomas for this reason rather than for reasons attributed to so-called neuroectodermal derivation. The junctional nevus as well as the seemingly anaplastic juvenile melanoma rarely are cancerous before puberty. In adults, about 12 per cent of the intradermal nevi are compounded with junctional nevi. The term "compound nevus" is suggested for such lesions. Evidence contradicts the impression that malignant melanomas arise from the common moles (intradermal nevi). When, as occurs in a minority of instances, a common mole is associated with a melanocarcinoma, the latter may be assumed to have grown from the overlying epidermal or junctional element of the compound nevus rather than from the intradermal nevus. The blue nevus and the mongolian spot are not epidermogenic but are most likely neurogenic. Because it may be assumed that nevi of the scrotum and of the palmar and plantar aspects of the extremities are junctional nevi, it would seem wise to remove such nevi prophylactically, preferably prior to puberty. The evaluation of the crucial transition from junctional nevus to malignant melanoma may require an extreme nicety of judgment. Criteria for this transformation in early or small lesions are described. Metastatic melanomas to the skin do not provoke the junctional change, and the absence of such change may be used reliably to differentiate a primary from a metastatic melanoma. Junctional nevi and small melanomas of the nipple of the breast may be easily confused histologically with Paget's disease. Similarly, many cases of so-called extramammary Paget's disease are in reality junctional nevi or melanomas.

**Treatment of Pneumonia.**—The efficacy of potassium penicillin G in a suspension of peanut oil with a dispersion of beeswax was investigated by Volini and his associates in the treatment of 104 patients with pneumonia who were admitted to the Cook County Hospital. The patients were given once daily an intramuscular injection of 1 cc. of a mixture containing 300,000 Oxford units of penicillin. The clinical response was good; the temperatures of over 60 per cent of the patients returned to normal within seventy-two hours. In many of the patients the levels of penicillin concentration were determined at intervals following injection, and it was found that they were more than adequate to effectively combat organisms causing pneumonia. There were no significant toxic reactions. The mortality rate was 3.8 per cent, but in all of the patients who died complications existed, so that pneumonia was not necessarily the chief cause of death. Complications and concurrent diseases existed in 32.7 per cent of the patients. The authors feel that patients who do not respond to treatment within seventy-two hours should be reinvestigated.

**Streptomycin and Penicillin in Gynecologic Conditions.**—Hesseltine presents in a table the therapeutic values of penicillin and streptomycin against organisms usually encountered in obstetric and gynecologic conditions. He stresses the importance of complete bacteriologic examination, not only to determine the offending organism, but also to ascertain its susceptibility to penicillin and streptomycin as a guide to therapy. Cultures should be obtained from the uterine cavity as well as the blood stream. The author and an associate made a special study on the prophylactic use of penicillin and streptomycin in patients in long labor, those treated by Dührssen's incision, intrauterine pack and other treatments commonly followed by a febrile course. They stress that streptomycin and penicillin are extremely valuable therapeutic aids in obstetrics and gynecology. Sufficient amounts must be given over an appropriate period of time. The parenteral route is the only acceptable one in obstetric and gynecologic complications. Other therapies such as blood transfusions, fluids, relief of bowel distention, drainage of abscesses and other routines must not be neglected. The author states that the antibiotics do not extend obstetric and gynecologic conditions for major surgery beyond the present accepted standards.

**Dental Diseases in Rheumatic Fevr.**—Entine observed that many patients with rampant dental caries have had rheumatic fever. A survey was instituted to ascertain whether the relation was accidental or whether rampant dental caries and heavy mucin deposits can be classified as symptoms or sequelae of the disease. The survey included 100 children with rheumatic fever and 100 normal children. The children with rheumatic fever were studied at outpatient and rheumatic fever clinics. The ages of the children varied between 4 and 17 years; the average was 9.5 years for the normal children and 10.3 years for those with rheumatic fever. The CRE index was determined in both groups of children. C indicates the number of carious penetrations of the enamel; R, the number of restorations, and E, the number of teeth previously extracted because of caries, plus the number of extractions necessary. The CRE index for normal children between the ages of 4 and 17 is 8.1. The CRE index for children with rheumatic fever, of the same age and socio-economic level, is 13.2. This represents approximately 60 per cent more dental caries in rheumatic fever patients than in normal children. This seems to indicate a relation between the streptococci associated with rheumatic fever and the greatly increased amount of streptococcic activity in the teeth as evidenced by caries. There is reason to suspect that in some cases a peculiar orange-brown mucin-like deposit around the necks of the teeth and on the occlusal surfaces is a symptom of rheumatic fever. In 33 per cent of the rheumatic fever patients nonsuppurative gingivitis is present.

**Sympathetic Conduction Pathways.**—Dissections of the sympathetic trunks and the communicating rami, carried out by Alexander and co-workers on human cadavers, and microscopic examination of sections of communicating rami and of spinal nerves revealed that aggregates of sympathetic ganglion cells lie imbedded in ventral spinal nerve roots and adjacent to nerve roots at the sites of origin of white communicating rami. These ganglion cells are synaptically connected with preganglionic fibers which reach them directly via the ventral nerve root. Most of them in turn send their axons distalward in the nerve trunk. In this manner sympathetic conduction pathways are formed which do not traverse the sympathetic trunk. They are not interrupted by sympathetic trunk extirpation or by section of the white communicating rami. Ganglions in the ventral nerve root or located adjacent to the root have been observed mainly in the first and the second thoracic and the first and the second lumbar segments. Because of connecting rami between the upper thoracic nerves and between the eleventh thoracic to the third lumbar nerves, the distribution of the sympathetic conduction pathways which are independent of the sympathetic trunk is not limited to the segments in which the ganglion cells concerned are located. These observations afford a more satisfactory explanation than formerly has been possible for failures to achieve complete sympathetic denervation by sympathectomy. Resection of the ventral roots of the second and the third thoracic nerves, in conjunction with resection of the white communicating ramus of the first thoracic nerve and interruption of the sympathetic trunk below its connections with the third thoracic nerve, probably would insure complete sympathetic denervation of the upper extremity in some cases. Resection of the ventral roots of the first and the second lumbar nerves, in conjunction with extirpation of the sympathetic trunk from the eleventh thoracic to the third lumbar segments, probably would insure complete sympathetic denervation of the lower extremity. In order to achieve permanent sympathetic denervation measures to prevent regeneration of the interrupted ventral root fibers would be necessary.

**Labyrinthine Surgery for Ménière's Disease.**—Lindsay, in a search for a method to prevent vertigo while preserving cochlear function, carried out several procedures on the labyrinth of 4 patients, 3 men and 1 woman between the ages of 32 and 55, with intractable Ménière's disease. Results showed that decompression of perilymph is of no value as a relief to Ménière's disease, or hydrops of the labyrinth. A fistula made in a bony semicircular canal through a simple mastoidectomy approach and left uncovered will probably remain a permanently open fenestra, which is undesirable because of the associated fistula symptom and Tullio phenomenon. Also a fenestra covered only by mucosa might offer less resistance to infection in case of subsequent middle ear suppuration. Closure of fistula can be assured at operation by making a very small opening and leaving bone chips in it, and probably by destruction or removal of the membranous labyrinth. The depression of the hearing threshold to a state of profound deafness in all four ears operated on, including that in which only a simple fenestra was created, suggests that the existence of a third window in the labyrinth in the presence of an intact conducting mechanism results in a definite threshold loss. Whether such a hearing loss in the first 3 patients would have been avoided by causing the fistulas to close, thereby limiting the procedure to the intralabyrinthine injury, has not yet been determined. The vertigo was relieved in all 4 patients.

**Streptomycin in Chronic Granuloma Inguinale.**—Nineteen cases of granuloma inguinale were treated by Samitz and his co-workers with a uniform total dosage of 20 Gm. of streptomycin administered in fractions of 0.5 Gm. every three hours for five days. All patients responded with rapid healing, and there were no recurrences during an observation period of six to fifteen months. There was one recurrence within three months among 4 patients treated with a total of 10 Gm. of streptomycin. There were no significant toxic reactions to the streptomycin treatment.

**Transfer of Metacarpal to Improve Function of Crippled Hand.**—Metacarpal transfer as described by Hyroop implies the transfer of a metacarpal with or without the attached digit, its tendons, nerves and vascular supply. In loss of the thumb with loss of the distal two thirds of the first metacarpal, with a good carpometacarpal joint, transfer of the index finger with the second metacarpal, with skin, blood vessels, nerves and tendons, will give an ideal result if all the muscles and tendons are present in the stump of the amputated thumb. Where the thumb with all of the first metacarpal is lost, the second metacarpal with the index finger may be transferred to the greater multangular carpus. Where there is amputation of the thumb with the first metacarpal and the index finger at the proximal joint, the second metacarpal may be transferred, with the palmar tissue, nerves and blood vessels, for a thumb. Where the thumb and index finger with their metacarpals are lost, the third metacarpal, with the long finger, may be transferred to make a thumb. Loss of the thumb and index finger with their metacarpals and amputation of the long finger at the proximal joint may indicate transfer of the third metacarpal, with palmar tissue, nerves and blood vessels. Where there is loss of the long finger with the head or all of the third metacarpal, transfer of the second metacarpal with the index finger, with or without bone graft, gives a good compact hand with normal function. Where there is amputation of the ring finger with the head or all of the fourth metacarpal, transfer of the little finger, with the fifth metacarpal, to the base of the fourth gives the same results as in the case of amputation of the long finger. The author stresses that these and other metacarpal transfer operations give the patient a hand that is ready for use in a short time. It has the advantage of carrying with it its own nerve and vascular supply. The special sensations of the hand, along with stereognosis, are retained.

Chronic Glomerulonephritis Complicating Pregnancy. M. Elizabeth Mussey.—p. 145.

**Aureomycin and Dihydrostreptomycin in Brucellosis.**—Herrell and Barber describe a new approach to the treatment of brucellosis in human beings, namely, the combined use of aureomycin and dihydrostreptomycin. It is not suggested that this is a specific form of treatment for brucellosis, but to date it appears to be the most effective method and, at the same time, the method which probably causes the least inconvenience to the patient and with which the lowest incidence of toxicity is associated when compared with previously available methods. The recommended plan of treatment consists of the administration of approximately 3 Gm. of aureomycin per day by the oral route combined with the simultaneous administration of 2 Gm. of dihydrostreptomycin per day by the intramuscular route. For acute brucellosis the average course of treatment should be twelve to fourteen days. In the treatment of culturally proved brucellosis with localizing lesions (brucellosis with complications) the course probably should be extended to twenty-one to twenty-eight days.

**Angiocardiography in Differential Diagnosis of Pulmonary Neoplasms.**—Neuhof and collaborators point out that Robb and Steinberg in 1938 presented observations concerning the role of angiocardiography in the interpretation of a variety of intrathoracic lesions. They noted changes in the branches of the pulmonary artery in tuberculosis and bronchiectasis, obstruction of the innominate vein by substernal goiter, and displacement of the great venous channels by mediastinal tumors or widespread fibrosing pulmonary lesions. Neuhof and associates used the Robb and Steinberg procedure with the addition of a multiple roentgen exposure technic. They aimed to ascertain the effects of various pulmonary neoplasms on the pattern of the pulmonary artery and its branches. The interpretation of the alteration has been materially aided by comparison with the films of operative specimens in which the pulmonary artery was injected with a radiopaque material. It was found that malignant lesions of the main bronchus often involve major branches of the pulmonary artery, causing compression, irregular distortion and varying degrees of obstruction. In those cases in which the infiltrating lesion arises from a small bronchus, similar changes involving smaller branches of the pulmonary artery are seen. In well circumscribed tumors, the adjacent vessels are spread apart and encircle the lesion. Mediastinal and pleural lesions cause no significant changes in the angiograms.

**Exploratory Thoracotomy in Diagnosis of Pulmonary Lesions.**—Johnson and his associates recently reviewed the records of 384 patients operated on by Clagett at the Mayo Clinic during the period 1942 to 1947 for lesions involving the lungs primarily. On the basis of the clinical records, laboratory findings and other diagnostic aids short of exploratory thoracotomy, a diagnosis could be made in 270 of these patients. In the remaining 114, it was necessary to resort to exploratory thoracotomy before a definite diagnosis could be established. On the basis of bronchoscopic and roentgenographic findings, these 114 cases were divided into three groups. The first group included all cases in which there was a mass lesion in the lung peripheral to the field of bronchoscopic visualization. In the second group were placed those cases in which the lesion was represented primarily by changes secondary to bronchial obstruction. Patients with lesions which could not be placed in either the first or second group were placed in a third or miscellaneous group. Thirty-nine of fifty-three mass lesions were proved to be malignant. Indications for removal existed in the majority of the benign lesions. The authors feel that the presence of a mass lesion of an indeterminate nature is an indication for exploratory thoracotomy. A malignant growth was detected at operation in 24 of the 48 cases in which the bronchoscopic and roentgenographic evidence was only that of bronchial obstruction. It had been impossible to make a positive diagnosis preoperatively. The 10 patients of the miscellaneous group were submitted to thoracotomy because the lesion failed to subside after a period of observation. Three of the 114 indeterminate pulmonary lesions remained indeterminate after exploratory thoracotomy. There were no deaths among the 25 patients who underwent exploration only. Six deaths followed pneumonectomy and 2 followed lobectomy. Exploratory thoracotomy is a valuable diagnostic measure.

Preservation of Internal as Well as External Anal Sphincter Following Resection of Rectum for Carcinoma: Case Report. R. R. DeNicola. —p. 91.

**Respiratory Emergencies in the Newborn.**—Goff advises a direct laryngoscopy for every newborn infant who fails to start respiration promptly or who shows signs of respiratory distress. Three posteroanterior roentgenograms of the chest should be taken in the cyanotic newborn infant. These will aid in the differential diagnosis of pulmonary, cardiac and cerebral pathologic conditions. Goff mentions congenital laryngeal stridor, abductor paralysis and membranous paralysis as laryngeal emergencies in the newborn. Congenital laryngeal stridor is a symptom rather than a disease, which is frequently due to a flabby larynx in which the false cords and arytenoids fall into the glottis on inspiration. In most cases the child will outgrow the weakness in a year. A congenital web between the cords requires incision with subsequent dilatation. Laryngomalacia, an anomaly in which both sides of the epiglottis curl in, needs only observation. A baby with complete stenosis of the larynx may pass as stillborn but would respond to immediate intubation or tracheotomy. The author discusses acute respiratory distress due to structural or pathologic changes in the lungs, such as atelectasis, pneumothorax, tracheoesophageal fistula, diaphragmatic hernia, thymus enlargement and lung cyst. Atelectasis is by far the commonest of the chest emergencies of the newborn. In the Swedish Hospital 157 cases of congenital atelectasis were observed among a total of 13,515 live births. Of the 95 premature infants with atelectasis 90 died, and of the 62 full term infants 30 died. The author makes a distinction between atelectasis due to an unexpanded, unaerated lung, and that due to bronchial obstruction from retained or aspirated secretions. In the latter case, tracheal or bronchoscopic aspiration is of value. In the unexpanded lung, special emphasis should be given to the early, gentle toilet of the respiratory passages, followed by the administration of oxygen and the maintenance of external heat. The pulmotor positive-negative resuscitator machines have killed more newborn infants than all other types of treatment combined. The author feels that most hospitals are not adequately equipped to resuscitate newborn infants. He has assembled an emergency outfit especially for use in the delivery room.

**Peritoneal Drainage in Abdominal Operations.**—Baker shows that diametrically opposed views have been expressed with regard to drainage, some advising "when in doubt drain" and others "when in doubt do not drain." He undertook a survey of certain groups of cases in an attempt to learn more concerning the advantages and the dangers of intraperitoneal drainage. He stresses the following points: 1. Except for the control of bleeding, there seems to be little value in the incorporation of gauze in abdominal drains. 2. Adhesions by fibrin completely isolate a drained point from the remaining cavity in a limited number of hours. 3. The practice of draining low points of the abdomen for injured areas higher up is unsound. 4. There are no means of measuring a person's susceptibility to bacterial organisms. 5. There are three indications for the use of drains in the abdominal cavity: first, to control bleeding; second, to provide an outlet for a localized infection and thus to prevent abscesses; and third, to produce a sinus tract through which substances may escape from a walled-off area within the abdomen without soiling the general peritoneal surfaces. 6. No fixed rule can be made to govern the use of peritoneal drainage; the problem is an individual one. 7. It is safest to follow the old dictum of Lawson Tait—"when in doubt drain." 8. Abdominal drainage involves an accurate knowledge of the physiology of the peritoneum. 9. The surgeon can obtain good results only as long as his operative maneuvers are in accord with the natural physiologic course of peritoneal response to disease.

Influence of Hormones from Adrenal Cortex on Dermal Spread of India Ink With and Without Hyaluronidase: Preliminary Report. Jeanette C. Opsahl.—p. 255.

**Streptomycin in Tuberculosis.**—A series of controlled in vitro and in vivo tests with tubercle bacilli in various mediums as well as controlled tests performed by Corper and Cohn in guinea pigs showed that streptomycin in vitro in amounts up to 1,000 units per cubic centimeter possesses no tuberculocidal action within one month of contact at 37 C. Streptomycin is not adsorbed or absorbed in active form by mammalian tubercle bacilli or by egg white or egg yolk in which it is not destroyed by heat coagulation of these materials. Streptomycin in vitro appears to act only during its presence in nutrient mediums, which does not explain the sustained retardant action in vivo on tuberculosis. Streptomycin exerts no appreciable discernible effect on the viability of virulent human tubercle bacilli in vivo, but it retards skin tuberculosis produced by the intracutaneous injection of virulent human tubercle bacilli as well as that produced by avirulent human tubercle bacilli. Treatment with streptomycin exerts a definite effect on the splenomegaly produced in guinea pigs by virulent or avirulent human tubercle bacilli. The drug did not appear to be able to prevent the natural development of specific tuberculoimmunity, specific tuberculoallergy or bacillary allergic intoxication. The action of the drug does not appear to be interfered with by loading the reticuloendothelial system with india ink or avirulent tubercle bacilli. In retarding tuberculosis, streptomycin does not appear to prevent a lethal effect from the intravenous infection with virulent human tubercle bacilli, in spite of the absence of macroscopically discernible tuberculosis in sufficient amount to account for death; resistance of the tubercle bacilli to the drug may play a part in this phenomenon. There is a likelihood that streptomycin does not act on tubercle bacilli per se in vivo as retardant to their growth as it does in vitro by direct contact, but that some intermediate mechanism accounts for its action on tuberculosis and consequently on tubercle formation.

**Typhus Vaccine Immunization.**—According to Sadusk, 64 cases of epidemic, louse-borne typhus were reported from the entire United States Army for the period 1942 to 1946; 603 cases of murine (endemic) typhus and 6,685 cases of scrub typhus (tsutsugamushi disease) were reported for the same period. There were no deaths among the 64 patients with epidemic typhus, who had been immunized with the epidemic typhus vaccine used by the United States Army. The vaccine consisted of a 10 per cent yolk sac suspension of the Breinl strain of Rickettsia prowazeki extracted with ether, containing both rickettsial bodies and "soluble antigen." Since early 1942 and throughout the war years three injections of typhus vaccine, 1.0 cc. each, were administered subcutaneously at an interval of 7 to 10 days, with stimulating doses every six months in endemic areas. Since 1944 the initial immunization series was reduced from three to two doses of vaccine. While no definite conclusions may be reached concerning reduction in incidence of epidemic typhus with this vaccine, the following points may be made: (1) evidence is accumulating to suggest that such incidence may be definitely lowered by adequate prophylactic immunization; (2) vaccination serves greatly to modify the clinical course of the disease if it occurs in adequately vaccinated persons; fever is much lower and of shorter duration than in persons not vaccinated, the period of hospitalization is markedly reduced, the extent and duration of rash are diminished, circulatory and nervous symptoms are lessened and the incidence of complications is brought down to a low figure; (3) the chance of death from epidemic typhus is practically nil if a person has been adequately immunized at least two weeks prior to exposure. The serologic findings in 5 of the 64 patients with epidemic typhus occurring subsequent to prophylactic immunization revealed that complement-fixing antibodies for epidemic typhus persisted for prolonged periods, while the Weil-Felix reaction and the reaction to the specific rickettsial agglutination test became negative in late convalescence. In all 5 cases it was highly probable that infection was sustained by pulmonary inhalation or conjunctival absorption of dust containing infected louse feces.

Rheumatological Hand and Finger Symptoms. E. Jonsson.—p. 72.

**Hyaluronic Acid and Rheumatic Disease.**—Cohen discusses the role of hyaluronic acid and the enzyme hyaluronidase in the causation of the phenomena of rheumatic diseases. It was believed previously that there is no common specific cause for the rheumatic disorders but that they have two common features, namely, the site of attack and the structural changes they exhibit. The site of the rheumatic lesion is in the skeletal tissues of mesenchymal origin, viz., connective tissue, fascia, muscle, ligament, joint capsule, synovial membrane, articular cartilage and even bone. Connective tissue consists essentially of collagen fibrils and of the interfibrillar ground substance or cement. Chemical studies have shown that among the constituents of this ground substance are chondroitin sulfuric acid and hyaluronic acid and that both of these can be acted on by the enzyme hyaluronidase. It appears that when the enzyme hyaluronidase attacks hyaluronic acid and other ground substances of connective tissue there occurs a series of changes analogous to those seen in rheumatic diseases. It has not been definitely established that a direct association exists between hyaluronic acid metabolism and rheumatism. The evidence is, however, suggestive, and a fruitful field of study has been revealed which merits further exploration.

*Some Observations on Curling's Ulcer. F. Braithwaite and P. H. Beales.—p. 284.

**Curling's Ulcer.**—According to Braithwaite and Beales ulceration of the duodenum following burns was first described by Curling in 1842. Harkins, in an extensive review of this condition in 1938, suggested that its incidence in severe burns was about 3.8 per cent, but the authors state that the incidence now is much lower. They ascribe this to modern methods of eliminating or reducing to a minimum bacterial infection of the burned areas. As early as 1894 it had been suggested that acute duodenal ulceration is associated with septic conditions as frequently as it is with burns and that the mechanism of production is the same in both cases. The authors report the histories of 2 patients with Curling's ulcer. They stress that Curling's ulcer is one of the late complications of burns. The lesion is found most commonly at the stage when the sloughs in third degree burns are separating; this is when tissue autolysis, exudation and infection are likely to be severest. The first of the patients cited had an extensive burn, covering approximately 65 per cent of his body. The ulcer was clinically evident eleven days after the injury. His treatment was adequate, but the extent of the burn was massive and infection with its resulting toxemia was inevitable. Forty per cent of his burn was third degree, with inevitable sloughs. The second patient shows that minimal sepsis may reactivate a dormant ulcer. In eight years, during which approximately 1,500 burns had been treated, only 3 examples of Curling's ulcer had been seen. This gives an incidence of 0.2 per cent. Some investigators have expressed the opinion that sepsis is the main feature in the production of Curling's ulcer. Penicillin is the most prominent recent factor in the control of sepsis. The introduction of penicillin has done much to diminish the incidence of Curling's ulcer. With modern treatment of burns aimed at prevention and control of infection and early skin grafting, this lesion will be encountered rarely, and then only in very extensive burns when the ideals of treatment are impossible to fulfil.

*Ciliary Action. V. E. Negus.—p. 57.
Observations on Co-ordination of Diaphragmatic and Rib Movement in Respiration. H. Herxheimer.—p. 65.

**Ciliary Action.**—Negus stresses that persons dealing with respiratory diseases should never lose sight of the dependence on cilia in the physiologic processes of the nose and sinuses. He discusses the mode of action and the various functions of the cilia and emphasizes that to preserve ciliary action, and to assist its highly important function of resisting infection, it is necessary to take such measures in the prevention and treatment of disease as appear of assistance to physiologic processes. Thus the blanket of mucus must not be washed away by nasal douches, nor must it be made too viscid by concentrated glycerin or too liquid by excessive use of potassium iodide. The secretions must not be dried by hypertonic solutions, by excessive use of amphetamine or atropine or by residence in an inefficiently conditioned building. Secretions must not be allowed to accumulate in a sinus or bronchus. Except for brief periods no drugs must be employed which have a toxic effect on the mucosa; cocaine, thymol and most powerful antiseptics are in this category. Obstruction to ciliary streams must be cleared, whether a plug of coagulated mucopus in the ostium of the maxillary sinus, a foreign body or a mass of new growth in a bronchus. If an operation is performed in an area covered by ciliated epithelium, every care must be taken to avoid permanent damage. Adenoids must be removed in such a way as to avoid formation of scar tissue and to allow regeneration; in a sinus the opening must not be overly wide, nor should the mucosa be removed if capable of recovering. The reaction of the secretions must be regulated to facilitate free action; a $p_H$ just above neutral appears best, and for this reason spray solutions are made slightly alkaline. The alkali reserve of the body may require correction on occasion. If ciliary action maintains its efficiency, then there will be no penetration of the mucosa by bacteria.

Operative Treatment of Female "Stress" Incontinence. H. Wahren.—p. 331.
Perirenal Abscess. Ola Obrant.—p. 338.

**Barge-Bourgain's Reaction in Genitourinary Tuberculosis.**—Sievers injected centrifuged Besredka, Sauton and Dubos substrates after the growth of a pathogenic strain of Mycobacterium tuberculosis of human type into guinea pigs with tuberculous inguinal lymph nodes. He thus produced in the animals a positive reaction similar to the "allergic reaction" to human serum produced by Barge and Bourgain in tuberculous guinea pigs. Control animals were unaffected. The longer the bacteria had been allowed to grow in the substrates, the stronger was the reaction. In the injected substrates on which cultures of M. tuberculosis have been grown, there must exist products that arise in association with the growth of the bacteria. No evidence was produced to show that the substances in the injected substrates were identical with the substances which appeared in some of the human serum with which Barge and Bourgain produced a positive reaction in tuberculous guinea pigs, but the reactions in both cases exhibited similar pictures suggesting that the Barge-Bourgain reaction may be a specific one. Berglin's clinical trial of the Barge-Bourgain reaction showed that diagnosis of tuberculosis was doubtful in only 1 of 41 patients with a primarily positive Barge-Bourgain reaction. Twenty-two of the 41 patients had urogenital tuberculosis, and 9 had tuberculous epididymitis. The Barge-Bourgain reaction was negative in 17 control patients with nontuberculous disease of the urinary tract; it was negative likewise in 23 control patients with nonurogenital diseases. Barge-Bourgain's reaction may therefore be considered specific from a diagnostic point of view in diseases of suspected tuberculous nature, particularly in the urogenital organs, in epididymitis and in obscure hematuria. The relatively short time required for the reading of the reaction facilitates an early diagnosis of urogenital tuberculosis. The parallelism apparently existing between the reaction and the activity of the tuberculous process seems to be of certain value in determining the suitable time for surgical treatment, which should not be instituted when the reaction is still positive.

**Potassium Metabolism After Surgical Intervention.**—Blixenkrone-Møller determined the potassium excretion in the urine of 24 patients in good general condition, who had been on an ordinary diet, had not been dehydrated and had not had any disturbances of metabolism. The potassium excretion was on an average 1,700 mg. per twenty-four hours, varying from approximately 400 to 2,400 mg. The excretion was lowest at night, generally somewhat greater in the forenoon than in the afternoon. Determination of the potassium excretion in 8 patients who had undergone operations (4 gynecologic operations, 2 cholecystectomies, 1 tendon suture and 1 extirpation of a parotid tumor) without parenteral administration of fluid revealed that the potassium excretion was greatly increased during the twenty-four hours following operation, especially during the afternoon. This increase is due to cellular dehydration due to the negative water balance. The potassium excretion during the twenty-four hours following operation was only half as large in 5 patients who had undergone operation on the stomach, colon or biliary tract, to whom adequate amounts of fluid were administered parenterally; in none of these patients did the potassium excretion exceed that which might be assumed to originate from tissue breakdown. Routine administration of potassium after surgical treatment is not required if adequate amounts of fluid are given. In dehydrated patients addition of potassium to the intravenous fluid is indicated. One case of abdominoperineal amputation of the rectum is reported in which 9,806 mg. of potassium was excreted during the first four postoperative days. Ten grams of potassium in dextrose, water and sodium chloride had to be administered within the next six days, until postassium balance was attained.

*Necrotizing Generalized Arteritis Due to Use of Sulfonamide Drugs. T. G. van Rijssel and L. Meyler.—p. 251.

**Arteritis Due to Sulfonamide Drugs.**—Van Rijssel and Meyler report 7 patients with a generalized necrotizing arteritis. In 6 with a fatal outcome, necropsy revealed necrotizing inflammation of the blood vessels, especially of the arteries. The walls of these vessels contained infiltrating cells, mononuclear and polynuclear cells, fibrinoid swelling and partial necrosis. The elastic fibers had vanished. The lumen of some of the vessels contained many polymorphonuclear leukocytes; a few vessels showed thrombosis. The tissue around the vessels was infiltrated with polymorphonuclear cells. One patient had lesions only in the kidneys, but the other 5 showed similar changes in the arteries of many organs, and some also showed signs of slight interstitial myocarditis. The authors feel that the allergic state was probably not brought on by the various infections. The symptoms appeared to be related to the administration of sulfonamide compounds, and the lesions were similar to those described in the American literature as allergic inflammation of the vessels due to sulfonamide drugs. The authors suggest that the noxious action of the sulfonamide compounds may be explained in two ways: 1. Sulfonamide compounds, after conjugation with protein, act as antigen which leads to allergic reactions. 2. Sulfonamide drugs cause disintegration of microorganisms, in this way liberating substances which act as antigens. The authors stress the need of caution in the administration of sulfonamide drugs. They should be given only in cases in which bacteriologic examination indicates that penicillin will be useless and only the sulfonamide drugs will counteract the causal organism. The sulfonamide drugs should never be given for fever only; if they are absolutely necessary they should be given in large doses for a short time. Their use over a long period in small doses is inadvisable, because it may sensitize the organism. The volume of the urine should be measured every day and should not be less than 1,500 cc. Allergic symptoms should be looked for: skin eruptions, conjunctivitis, eosinophilia, polyneuritis, changes in the urine, polyarthritis, asthma, restlessness; if they are present use of the drug should be discontinued immediately.

*Surgical Treatment of Hypertensive Cardiopathy and of Cardiac Insufficiency from Hypertension. I. Chávez and L. Méndez.—p. 680.

**Surgical Treatment of Hypertensive Cardiopathy.**—Chávez and Méndez performed a lumbodorsal sympathectomy on 11 patients with hypertensive cardiopathy complicated by grave cardiac insufficiency. One of the patients died from cerebral hemorrhage eleven days after the operation. Another patient had undiagnosed meningitis of long duration. He died on the day after the operation from occlusion of the aqueduct of Sylvius. A third patient died from uremia ten months after the operation. Eight patients experienced great improvement. The good results have persisted for periods which vary between one year and a half and three years after the operation. All the patients were reported to be in satisfactory condition with no recurrence of cardiac insufficiency. Some of the patients had returned to work. The authors believe that hypertensive cardiopathy is an indication for sympathetic resection, which constitutes the only treatment capable of stopping the progress of the myocardial damage. Cardiac insufficiency, even in cases in which the disease does not respond to digitalis, can be controlled by operation, provided that the coronary, myocardial and other visceral lesions are not severe and cardiac insufficiency is not of long duration.

"Arsphenamine Rheumatism" and Its Modification by Calcium Thiosulfate. F. Voss.—p. 212.

**Laboratory Infection with Q Fever.**—Nauck and Weyer say that in August 1947 there developed in their typhus laboratory a number of febrile attacks in which Rickettsia of the wolhynica type were demonstrated by means of the louse test. These cases were responsible for the fact that the first cases of laboratory infections with Q fever were mistaken for Wolhynic fever or typhus. The first case of Q fever appeared on November 6, but this case was identified as such only in retrospect. The first case in which the diagnosis of Q fever was established occurred on Nov. 21, 1947, and the last on Feb. 21, 1948. During this time 7 definitely verified cases occurred and 4 doubtful ones. The clinical aspects of these cases were the same as those reported in other laboratory epidemics. In 4 of the cases they verified the diagnosis by the demonstration of the causal organism following the introduction of blood into mice or guinea pigs, by transferring sputum to mice, by letting lice or ticks feed on patients or by inoculating mice with organ pulp. Even after the fever subsides the causal organism may still be present in the blood, but this could not be demonstrated in all of the patients. Verification of the diagnosis by complement fixation reaction was impossible, because the antigen supply was inadequate. The cases of Q fever appeared only after the strain of Q fever Rickettsia, which was maintained in lungs and spleens of mice, had passed through ticks. The specific source of infection is not known, but infection by dust containing the causal organism is most likely. Fluctuations in virulence may explain some of the peculiar epidemiologic aspects of Q fever. Since this report was completed 2 additional cases of laboratory infection with Q fever occurred. In these cases again infection by dust seemed most likely.

**Tuberculin Test and Roentgen Examination in Tuberculous Children.**—The manner in which the tuberculin test is used at present involves only a local reaction, which is all that is desired because the production of a focal reaction involves risks. In view of the population density and prevalence of tuberculosis now existing in Germany, more than 90 per cent of the adults have been infected with tubercle bacilli some time during their childhood. A positive reaction to a tuberculin test is therefore of little significance in adults. A positive reaction in a child signifies only that the child has had contact with the toxin of tuberculosis. The focus must be found, and after it has been established, various diagnostic procedures must be used in order to establish the biologic reactivity. Results of cutaneous tests must be evaluated with great caution. Intercurrent diseases, such as measles, scarlet fever, whooping cough and mumps, modify the allergic status and may cause a negative reaction. They may also stimulate the progression of the tuberculous process. Thus the cutaneous test may fail to disclose the true status at a time when the danger of progression or activation is especially serious. A diet low in protein decreases the antibody formation, and for this reason failures of cutaneous tests are particularly likely at present. In spite of these shortcomings, the cutaneous test is indispensable in the evaluation of the tuberculous process. The author demonstrates the value of roentgenologic studies in the course of tuberculosis. Roentgenoscopy detects hidden foci; roentgenograms are valuable records which permit comparisons at a later examination. The clinical interpretation of the roentgenologic observations in children must take account of the fact that exudative reactions predominate in children. The author discusses roentgenologic aspects of the forms of tuberculosis that are characteristic of childhood, particularly the primary complex and tuberculosis of the hilar region. Although there are other valuable methods of examination for tuberculosis in children, they are definitely less important than the combined use of tuberculin tests and roentgenoscopy in the diagnosis and prognosis of tuberculosis in children.

### 61:97-112 (Feb. 18) 1949

Introduction in Treatment of Tuberculosis of Larynx. A. I. Cemach.—p. 97.
*Embolectomy Performed on Abdominal Aorta. W. Dick.—p 99.
Contribution to Neurogenesis of Peptic Ulcer. L. P. Avancini.—p. 104.
*Blood Transfusion Syphilis. L. Arzt.—p. 105.

**Embolectomy.**—Dick treated 5 patients with embolism of the abdominal aorta at the bifurcation into the two iliac arteries by embolectomy. Two of these cases, 1 in a child aged 2½ years and the other in a woman aged 22, are reported in detail. The direct retroperitoneal approach was employed in all 5 cases. Lumbar anesthesia was used in the 4 adult patients, while a few drops of ether were sufficient in the case of the child. Treatment with methylene-dioxybenzyl-methyl-methylene-dioxy-isoquinoline (eupaverin) was instituted in 3 of the author's cases before the surgical intervention, but was ineffective. Intravenous or transcutaneous, intra-aortal injections of eupaverin should be given nevertheless in all cases in which embolism of the aorta is suspected; it may be simulated by vascular spasm and in such a case the drug will be effective. Surgical intervention should not be postponed for more than one hour if definite improvement does not result from treatment with eupaverin. Embolectomy should be performed within the first six hours after the embolism when the intima of the vessel has not yet been impaired and when secondary thrombosis has not occurred. Twelve hours after the embolism sympathectomy and resection of the occluded portion of the vessel rather than embolectomy should be performed. In 2 of the author's cases heparin sodium injections were given immediately after the suture of the vessel: Disturbances of healing did not occur. Thrombosis threatens only for the first few hours after embolectomy and, therefore, heparin sodium, but not dicumarol,® is indicated.

**Blood Transfusion Syphilis.**—According to Arzt, the percentage of transmission of syphilis by blood transfusion is not known, but 1 infection per 4,000 cases may be admissible for certain countries in certain times. The process of infection with Treponema pallidum by transfusion differs from that by cutaneous route in that there is no filtration through the lymph nodes and in that the infective material is much more massive, considering the transfusion of 300 to 500 cc. of blood. The most dangerous donors are persons in the first incubation period, in the absence of any clinical symptoms and serologic proof. The right selection of the donor is the essential point in the problem of prevention of syphilis by blood transfusion. Persons with serologically latent syphilis should be rejected. Professional blood donors should be preferred to occasional donors among relatives of the patient. Professional donors are examined first on registration and have to undergo regular control examinations by a venereologist. Immediately preceding the transfusion a renewed clinical, and if possible serologic, examination, at least with a rapid reaction, should be made. Donors with serologically negative reactions who present symptoms from which syphilis may be expected and particularly donors with negative reactions with manifestations of any kind at the genitals should be rejected. The risk of transmission of syphilis may be reduced by the use of blood or serum treated with sodium citrate and preserved by refrigeration, instead of fresh blood; the donor of the blood which is to be preserved should be subjected to a Wassermann test.

# Book Notices

**Blood Transfusion.** By Elmer L. deGowin, M.D., Associate Professor of Internal Medicine, State University of Iowa, Iowa City, Robert C. Hardin, M.D., Assistant Professor of Internal Medicine, State University of Iowa, Iowa City, and John B. Alsever, M.D., Senior Surgeon, United States Public Health Service. Cloth. Price, $9. Pp. 587, with 200 diagrammatic drawings. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W.C. 2, 1949.

Few fields of medical practice have expanded in recent years as rapidly and as successfully as transfusion of blood, plasma and their substitutes. The number of indications has increased tremendously, the danger of reactions has been reduced to a small fraction of what it was only ten or fifteen years ago. The qualifications of the three authors are attested to by the various positions held by them and by the long list of their contributions to the subject of the monograph.

The indications for the use of blood, plasma and substitutes, shock, the theory and practice of blood grouping (including the Rh factor, and of pretransfusion tests, the technic of transfusion of blood and plasma, the preparation of plasma, blood derivatives and plasma substitutes and the organization and management of a transfusion service and of blood banks are the subjects dealt with in 27 chapters. The lucidity of presentation of some of the most difficult subjects in medicine is admirable, as is the thorough and complete treatment. Ample bibliographic references are included in each chapter. The index is well organized. The book deserves widespread use by physicians, surgeons, clinical pathologists, blood bank directors and medical technologists.

**The American Soldier: Adjustment During Army Life. Volume I.** By Samuel A. Stouffer and others. Studies in Social Psychology in World War II. In Two Volumes. Cloth. Price, $7.50; $13.50 per set of 2 volumes. Pp. 599, with 17 charts. Princeton University Press, Princeton, N. J., 1949.

**The American Soldier: Combat and Its Aftermath. Volume II.** By Samuel A. Stouffer and others. Studies in Social Psychology in World War II. Cloth. Price, $7.50; $13.50 per set of 2 volumes. Pp. 675, with illustrations. Princeton University Press, Princeton, N. J.; Oxford University Press, Amen House, Warwick Sq., London, E.C. 4, 1949.

Tolstoy long ago wrote in his book War and Peace, "In Warfare the force of Armies is the product of the mass multiplied by something else, an unknown X." In an effort to determine this unknown factor, the Research Branch, Information and Education Division, United States Army, interviewed more than half a million soldiers during World War II. Never before had modern methods of social science been employed on so large a scale by such competent technicians. The Army exercised no control on the interpretations or conclusions expressed in these volumes, which are the sole responsibility of the authors in their capacity as civilian social scientists. A major purpose of the research staff was to provide a base of factual knowledge which would help the director of the Army Information and Education Division in his administrative and policy decisions.

The reliability of facts deduced from the interpretation of statistics depends on numerous variables; however, it would appear from the material presented by the authors that proper recognition of these variables and numerous cross checks have strengthened the validity of the statistical deductions. The mass of charts, figures and tables does not lend itself to rapid assimilation, and long periods of study are essential for a proper understanding of the contents.

Volume I, "Adjustment during Army Life," concerns itself primarily with the personal reaction of the soldier to his military environment. The soldiers' attitudes were analyzed in relation to variables such as age, level of education, marital status and color. The attitudes studied ranged from the soldier's reaction toward his superior officer through such analyses as job satisfaction, and other factors relative to his adjustment.

Volume II, "Combat and its Aftermath," studies the attitudes and aptitudes of the soldier in relation to combat. The authors show a definite correlation of precombat attitude with combat performance. Furthermore, according to their interpretation of collected statistics, the better educated men, those with the highest mechanical aptitude scores, the older men and the married men tend to get the better performance ratings in combat. Further studies include combat motivation, the control of fear in combat, problems of combat replacements, attitudes of ground combat troops toward rear echelons and the home front, problems of rotation and reconversion, and the point system for redeployment and discharge.

This work is primarily of importance to the National Military Establishments; nevertheless the information presented and the mechanics of collection of data developed should interest students of civilian social psychology. The many authors who were engaged in the assemblage of this material should receive a certain sense of gratification from the knowledge that this gigantic task will provide further impetus for a great advance in the social relations of man.

**The Commonwealth Fund Thirtieth Annual Report for the Year Ending September 30, 1948.** Paper. Pp. 48. Commonwealth Fund, Division of Publications, 41 E. 57th St., New York 22, 1949.

Entering on its thirtieth year devoted to doing something "for the welfare of mankind," the Commonwealth Fund reviews in its annual report the projects undertaken during the past year.

Most important of these projects is the attempt to better patient-physician relationships in cases involving mental health. By joining forces with medical schools to add psychiatrists to the teaching staffs, by giving fellowships to advanced workers dealing with mental cases and by making arrangements for interns to receive the feeling of general medical practice in rural hospitals, the Commonwealth Fund has been able to demonstrate to the physician the importance of realizing the mental situation of his patient.

Closely related to this medical education is the preventive service aiding mental health which is taught through lectures, clinical work and discussions. The stress here, too, is on personal attention in treatment. Field work is done on a county or state basis.

In addition to aiding rural hospitals build and equip, the fund supports the Council of Rochester Plan, begun in 1946. Small hospitals receive benefits in knowledge of organization and medicine from adjacent larger hospitals.

Other projects include three or four year grants for medical research and awarding of twenty-eight fellowships, now given under less limiting requirements for eligibility. The ten books and pamphlets published are also listed, and the report closes with a balance sheet of the Commonwealth Fund and a list of the appropriations voted during 1947-1948.

**A Treatise on Obstetric Labor.** By Richard Torpin, M.D., Professor and Chairman of the Department of Obstetrics and Gynecology, University of Georgia School of Medicine, Augusta, Georgia. Chapter on Erythroblastosis Fetalis and the Rh Factor. By Edith L. Potter, M.D., and Philip Levine, M.D. Cloth. Price, $7. Pp. 590, with 185 illustrations. Augusta Obst. and Gyn. Book Co., Box 2038, Hill Branch, Augusta, Ga., 1948.

The book was prepared for physicians and obstetricians. The opening chapter is called Test of Labor. The sequence of chapters is surprising in that the chapter on amnesia, analgesia and anesthesia follows a discussion of the pelvis, and in this chapter alone 118 articles are quoted. Much of the book is supplied by quotations from other authors or from previous publications. In the section on rural obstetrics, the idea of early ambulation is supported.

In the chapter dealing with forceps delivery, some of the reproductions are poor. The illustrations on postpartum hemorrhage are meritorious. Immediately after this chapter there is one dealing exclusively with the retained placenta.

Chapter XIV is a reprint from The Journal of the American Medical Association dealing with the influence of the placenta on the fetal presentation. In the chapter on placenta previa, the drawings do not reveal placenta previa, and thus the insertion of the bag fails to illustrate the effect of the tampon.

In the treatment of abortion (page 299), he states, "scraping or curetting of the uterine lining is not necessary and is dangerous. . . ."

The advice on care of the intrauterine dead fetus is good. The discussion on puerperal sepsis seems incomplete. On page

# Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

## ARTHRITIS AND BEER DRINKING

*To the Editor:*—Does drinking beer cause arthritis or arthralgia? Is this true arthritis or an allergic response? M.D., Texas.

[This inquiry was referred to two authorities, whose respective replies follow.—ED.]

ANSWER.—Certain evidence that beer drinking causes arthritis or arthralgia is lacking. On theoretic grounds one may assume that it is possible to be allergic to one or more ingredients of beer, and that on these grounds an allergic arthritis might follow its consumption. Such a situation must be rare, however, if it occurs at al[illegible]en in gout, there is lack of evidence that the intake of [illegible] detrimental effect on the disease

been called psychokinesis. This effect has been demonstrated in our laboratory experiments repeatedly. It is still, however, a new finding and has not received wide recognition as yet.

2. Scientific research regarding these questions is under way at present. The principal research center is the Parapsychology Laboratory at Duke University. Next in amount of activity is the Department of Psychology, City College of New York, which works in conjunction with the American Society for Psychical Research. Work by individuals is going on, however, in many colleges and universities over the country, but only in a minor, part time fashion.

3. With respect to research as to the immortality of the soul, only preliminary studies for the purpose of developing suitable methods are being carried out. This is going on at Duke University.

## RABIES VACCINE PARALYSIS

*To the Editor:*—A woman aged 22 was bitten by a rabid dog six weeks ago, at which time she was in perfect health. She was at once started on antirabies treatment with vaccine approved by the Kentucky State Board of Health. The doctor was giving this each day and in alternate arms. The eleventh dose came in the right arm; two hours after the injection the patient was seized with severe pain in the right shoulder, and some two hours later was completely paralyzed from the neck down. This lasted for several days but did not involve the muscles of deglutition or respiration enough to embarrass the patient. After two weeks she regained sensation of the body from the umbilicus up, and also motion and reflexes. Five weeks after the inception of the paralysis she had no action of the bladder or bowel. She had a catheter in the bladder and did not know when the bowel should move. Reflexes were absent from the umbilicus down. This patient had chronic headache. She had frequent and rather severe attacks. I started treatment with sodium iodide. The patient's reaction to histamine was highly positive. What can be expected as to recovery? Will other treatment be more successful?

A. David Willmoth, M.D., Louisville, Ky.

ANSWER.—Occasionally, in a patient who is receiving active treatment for rabies with an attenuated form of rabies vaccine, encephalomyelitis develops. This disease may take on one of three forms: (1) paralysis of a type found in rabies; (2) myelitis of either cervical, thoracic or lumbar regions, or (3) polyneuritis with facial paralysis. Why this disease develops during the treatment is not fully understood. The fact that an attenuated form of rabies vaccine is used in the therapy strongly suggests an attenuated form of hydrophobia. Some authors are inclined to believe that the vaccine used releases another virus, akin to that in rabies, because the clinical picture resulting is like that seen in hydrophobia. There is no scientific treatment for antirabic encephalomyelitis. At best any therapy is purely or entirely symptomatic. The outcome is usually or frequently disastrous in that the patient may die. When this does not occur the patient may recover with only a small amount of residual effects. On occasions, however, the paralysis may become permanent. Certainly all injections of vaccine should be stopped once this antirabic picture develops. Despite the fact that encephalomyelitis may follow injections of antirabic vaccine it is strongly suggested that whenever a case of rabies presents itself and one is sure that the biting culprit has hydrophobia, antirabic vaccine therapy should be started at once.

## RABIES VACCINE AND RAT BITES

*To the Editor:*—As health officer, I am frequently presented with the problem of whether or not to give rabies vaccine following rat bites. There is considerable difference in opinion among health officers, epidemiologists and veterinarians as to whether or not this prophylactic measure should be used. In the East St. Louis area, we have not had a reported positive dog head in almost two years. In the past, my policy has been to give rabies vaccine to all rat bite patients referred by their family physicians for such treatment. In many cases, especially in small babies, I have been reluctant to do so, but I would not desist because of legal complications. Recently, a physician called concerning this matter. A child had been bitten on the finger by a rat. I told him that the danger of complications in the indescriminate use of rabies vaccine must be weighed against the possibility of rabies resulting from a rat bite. I feel the chances of rabies developing in this instance are less. Is my reasoning sound?

C. F. Leonard, M.D., East St. Louis, Ill.

[This inquiry was referred to two authorities, whose respective replies follow.—ED.]

ANSWER.—As rat bites do not cause rabies there is no reason for using rabies vaccine in such cases. It is well known that rabies vaccine by itself in some cases may cause undesirable reactions.

ANSWER.—Rats are susceptible to rabies and theoretically constitute a possible reservoir and source of infection for man. Actual experience in this country has shown that the num-

484, the statement reads, "The lower uterine segment operation is relatively safely done on a patient who has been in labor even several days if there have been no vaginal examinations, and if regular intravaginal anti-septics have been used, due attention having been paid to prevention of anemia, dehydration and discomfort of the patient."

Just before the index there are 73 case reports.

This is obviously a book of subjects which does not completely span the entire field of obstetrics but with irregularity and imbalance in the degree of interest. The bibliography is impressive.

**Practical Aspects of Thyroid Disease.** By George Crile, Jr., M.D., F.A.C.S., Department of Surgery, Cleveland Clinic, Cleveland, Ohio. Cloth. Price, $6. Pp. 355, with 101 illustrations. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W.C. 2, 1949.

According to the preface the author's conclusions are based on his experience in the surgical treatment of 1,000 patients with diseases of the thyroid plus observations of several hundred patients with hyperthyroidism treated with antithyroid drugs by one of his colleagues. Most thyroid diseases have moved from the domain of the surgeon to general practice. As a consequence both internists and surgeons will need to familiarize themselves with the recent developments in the diagnosis and treatment of diseases of the thyroid and to cooperate more closely than heretofore.

The book has 27 chapters, 1 of which is devoted to the anatomy and 1 to the physiology of the thyroid. One is devoted to a discussion of the diagnosis of hyperthyroidism. The author's opinion of the value of blood iodine determinations will be comforting to the many clinicians who do not have access to facilities for this test. He points out that the test is difficult and expensive and says that the results are too irregular and inconsistent to be of clinical value.

The chapter devoted to "Anti-Thyroid Drugs in the Treatment of Hyperthyroidism" is particularly good, as is the chapter on "Roentgenotherapy and Radioactive Iodine in the Treatment of Hyperthyroidism." Eight chapters are devoted to various aspects of the surgical treatment of hyperthyroidism.

A.T. 10 (dihydrotachysterol), which is esteemed highly by many men in the treatment of hypoparathyroidism, is viewed with suspicion by the author, who feels that its use entails some danger by its cumulative effect in raising the serum calcium to toxic levels. He favors the use of vitamin D in doses of 50,000 to 300,000 units daily. He could have made the discussion of cretinism and mongolism more helpful by enumerating the five characteristics of mongolism not seen in cretinism. The bibliography is well chosen and sufficiently extensive.

**Erkennung und Behandlung der organischen Lösungsmittelvergiftungen.** Von Dr. Med. Franz Borbely, Chefarzt des Fabrikkrankenhauses der Manfred Weiss Stahl- und Metallwerke A.-G. Budapest. Geleitwort von Prof. Dr. Fritz Schwarz, Direktor des Gerichtlich-Medizinischen Instituts der Universität Zürich. Paper. Price, 13.80 Swiss francs. Pp. 168. [Sole distributors for the U. S. A. and Canada: Grune & Stratton, Inc., 381 Fourth Ave., New York.] Hans Huber, Marktgasse 9, Bern, 1946.

Clinical aspects of acute and chronic poisoning by the common industrial solvents are stressed in this monograph. About 20 pages are devoted to the clinical symptoms and syndromes of poisoning by solvents in general and about 100 pages to individual solvents, for each of which is given its nonspecific and specific actions; the clinical course, diagnosis, prophylaxis and therapy of poisoning by the solvent; and a short bibliography, chiefly of European publications. The solvents covered are: aliphatic hydrocarbons; methyl, ethyl, propyl, butyl and amyl alcohols; dioxane; aldehydes and ketones, especially acetone; ethers, especially diethylether; formates and acetates; dimethyl sulfate; fifteen common aliphatic chlorinated hydrocarbons; carbon disulfide; aromatic hydrocarbons, alcohols, esters, acids and chlorine compounds; cyclohexane and related hydrocarbons, and terpenes. The first part of the book acquaints the doctor with the names of solvents commonly used for: extracting fats and formulating protective coatings, rubber compounds and plastics, for heat exchange mediums, fuels, explosives, fire extinguishers, etc. Typical accidents causing acute poisoning are described. Because the average workman often does not know the chemical nature of solvents to which he is exposed, because solvents often are marketed under fanciful names and because differential diagnosis of solvent poisoning is difficult, the doctor is advised to secure samples of solvents when poisoning is suspected. A little information is given on the qualitative analysis of such samples. The book is written in simple German, and is well organized and indexed.

**School Health Education: A Textbook for Teachers, Nurses and Other Professional Personnel.** By Delbert Oberteuffer, Ph.D. Harper's Series in School and Public Health Education, Physical Education, and Recreation. Delbert Oberteuffer, Editor. Cloth. Price, $3.25. Pp. 405. Harper & Brothers, 49 E. 33d St., New York 16, 1949.

This book is a text for the preparation and in-service education of teachers and administrators and other personnel in school health education. The major portion of the material is devoted to school health education procedures and policies, but considerable attention is given in the third section of the book to the health service activities, including healthful school living. Emphasis is placed on methods and practices which have proved successful in actual school situations. Specific health problems confronting the schools are described and the role of effective health education in solving these problems is outlined. The task of the schools in health education is defined as revealing the facts and meanings of the work of the scientist and placing appropriate interpretations and applications on them. How this objective, with stress on bringing about desirable health behavior, can be accomplished through direct teaching, correlation and integration of health in the curriculum is presented in considerable detail. Suggestions as to methods and procedures for organization and evaluation of instruction are also made.

Physicians will be interested in the attention given to the necessity for one's developing critical thinking through health education about scientific health services as compared to spurious healing cults and "patent medicines and cures." Suggestions as to the reciprocal relations which can exist between the school health program and physicians, dentists and their professional societies are made.

**Investigations on Agonal Acidosis..** By Ib Fabricius Hansen. Edited by Geoffrey Walker, B.Sc. Translated by Hans Andersen, M.D. Paper. Pp. 135, with 15 illustrations. Stechert-Hafner, Inc., 31 E. 10th St., New York 3; Povl Branners Forlag A/S, St. Kongensgade 29, Copenhagen, 1948.

This monograph on the chemical changes in the blood during the agonal state was completed shortly before death prematurely terminated the promising career of the author. It contains the most detailed studies with which the reviewer is acquainted on the chemical composition of the blood during the transition from life to death. Following introductory sections on previous work on agonal acidosis, the clinical aspects of the preterminal state and the concept of acidosis, there is a description of the material and analytic methods used. The results are presented in great detail, with tabular summaries. Twenty-three chemical and physiochemical measurements were carried out on almost all the 38 subjects studied. Unfortunately, sodium and potassium determinations were not done. There is a short section on therapy.

Hansen found a fall in blood $p_H$ usual in the agonal state. In 18 of the cases values of less than 7.10 were found. The lowest premortal $p_H$ was 6.80. Since the $p_H$ was below 7.00, the lower limit generally regarded as compatible with life, in one third of the patients, it seems likely that in some the acidosis was the direct cause of death. The acidosis was most often of the mixed type, with both metabolic and respiratory components. In contrast to $p_H$, plasma bicarbonate is reduced in only about a third of the cases; the carbon dioxide tension is often increased. The lactic acid content of the blood is augmented in the agonal state. Hansen found no correlation between the cause of death and the severity of the acidosis, but the observations indicated that the fall in $p_H$ is directly proportional to the final period of unconsciousness. The therapeutic value of drugs increasing the irritability of the respiratory center, oxygen, and the intravenous administration of 1.3 per cent solution of sodium bicarbonate are briefly discussed.

The mass of data on the chemical state of the blood in the agonal state should interest workers in various clinical and biochemical fields.

# Queries and Minor Notes

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

## ARTHRITIS AND BEER DRINKING

**To the Editor:**—Does drinking beer cause arthritis or arthralgia? Is this true arthritis or an allergic response? M.D., Texas.

[This inquiry was referred to two authorities, whose respective replies follow.—Ed.]

Answer.—Certain evidence that beer drinking causes arthritis or arthralgia is lacking. On theoretic grounds one may assume that it is possible to be allergic to one or more ingredients of beer, and that on these grounds an allergic arthritis might follow its consumption. Such a situation must be rare, however, if it occurs at all. Even in gout, there is lack of evidence that the intake of beer has a detrimental effect on the disease.

Answer.—Drinking beer is not known to cause arthritis. Patients with gout may have attacks of acute gouty arthritis more frequently if indulging in beer or other alcoholic beverages. Though the cause of gout is unknown, alcoholic beverages, per se, are not thought to be a primary etiologic factor.

Presumably, allergy to malt might be manifested by use of beverages, such as beer, in which malt is a basic constituent, but in such an instance allergic manifestations to malt in other forms also would be demonstrable.

## RESEARCH ON IMMORTALITY

**To the Editor:**—Since a recent newspaper story about Dr. Rhine of Duke University, I have had a number of questions asked that I cannot answer and I should appreciate information about them. The story was in reference to his belief that the immortality of the soul could be proved by science, and also referred to his work on mental telepathy. I should also like your answer to the following questions: 1. What is the present accepted scientific status as to mental telepathy, spiritualism and one's control of dice and cards, as Dr. Rhine describes? 2. Is there any other scientific research under way at the present time regarding these questions? 3. Is there any research now going on as to the immortality of the soul? Please describe.

M.D., Tennessee.

Answer.—The Association for Research in Nervous and Mental Diseases, which includes leading neurologists and psychiatrists of America, has been considering a scientific study of extrasensory perception. Most of these specialists felt that the data that had been accumulated should be evaluated scientifically. The subject may be reviewed at a forthcoming meeting. Many members not only expressed an interest in the subject but stated that they had observed psychologic phenomena which might be classed as extrasensory perception or mental telepathy.

With the perfection of the electroencephalogram, demonstration can be made that the brain does send out electrical impulses which can be recorded. These waves, at present, can be used only in the process of diagnosis and can be defined as either pathologic or normal. Possibly the specific waves can be more definitely interpreted. Theoretically, such waves might be considered an indication of thought transmission. At present, means do not exist for recording thought waves visually.

The immortality of the soul is considered a philosophic problem and is dependent on the definition of the soul.

As J. B. Rhine states, in man's attempt to make clear to himself his position in the universe, he has created various religions, and with the development of culture many speculative philosophies have been concocted out of untested logic. With the advent of science, ways of finding out the truth have been devised. This does not necessarily mean that man's conception of the Infinite will be proved incorrect. It is only by the understanding of man himself that the soul can be understood.

[The questions were also referred to Dr. J. B. Rhine, who replies:]

Answer.—1. There is a fairly respectable amount of acceptance of telepathy among scientists, and this is noticeably growing. There is no scientific acceptance of spiritualism worthy of attention. An occasional scientist has expressed acceptance of the claims of the spiritualists, but I know of no one living today who does. The control of dice by direct mental influence has been called psychokinesis. This effect has been demonstrated in our laboratory experiments repeatedly. It is still, however, a new finding and has not received wide recognition as yet.

2. Scientific research regarding these questions is under way at present. The principal research center is the Parapsychology Laboratory at Duke University. Next in amount of activity is the Department of Psychology, City College of New York, which works in conjunction with the American Society for Psychical Research. Work by individuals is going on, however, in many colleges and universities over the country, but only in a minor, part time fashion.

3. With respect to research as to the immortality of the soul, only preliminary studies for the purpose of developing suitable methods are being carried out. This is going on at Duke University.

## RABIES VACCINE PARALYSIS

**To the Editor:**—A woman aged 22 was bitten by a rabid dog six weeks ago, at which time she was in perfect health. She was at once started on antirabies treatment with vaccine approved by the Kentucky State Board of Health. The doctor was giving this each day and in alternate arms. The eleventh dose came in the right arm; two hours after the injection the patient was seized with severe pain in the right shoulder, and some two hours later was completely paralyzed from the neck down. This lasted for several days but did not involve the muscles of deglutition or respiration enough to embarrass the patient. After two weeks she regained sensation of the body from the umbilicus up, and also motion and reflexes. Five weeks after the inception of the paralysis she had no action of the bladder or bowel. She had a catheter in the bladder and did not know when the bowel should move. Reflexes were absent from the umbilicus down. This patient had chronic headache. She had frequent and rather severe attacks. I started treatment with sodium iodide. The patient's reaction to histamine was highly positive. What can be expected as to recovery? Will other treatment be more successful?

A. David Willmoth, M.D., Louisville, Ky.

Answer.—Occasionally, in a patient who is receiving active treatment for rabies with an attenuated form of rabies vaccine, encephalomyelitis develops. This disease may take on one of three forms: (1) paralysis of a type found in rabies; (2) myelitis of either cervical, thoracic or lumbar regions, or (3) polyneuritis with facial paralysis. Why this disease develops during the treatment is not fully understood. The fact that an attenuated form of rabies vaccine is used in the therapy strongly suggests an attenuated form of hydrophobia. Some authors are inclined to believe that the vaccine used releases another virus, akin to that in rabies, because the clinical picture resulting is like that seen in hydrophobia. There is no scientific treatment for antirabic encephalomyelitis. At best any therapy is purely or entirely symptomatic. The outcome is usually or frequently disastrous in that the patient may die. When this does not occur the patient may recover with only a small amount of residual effects. On occasions, however, the paralysis may become permanent. Certainly all injections of vaccine should be stopped once this antirabic picture develops. Despite the fact that encephalomyelitis may follow injections of antirabic vaccine it is strongly suggested that whenever a case of rabies presents itself and one is sure that the biting culprit has hydrophobia, anirabic vaccine therapy should be started at once.

## RABIES VACCINE AND RAT BITES

**To the Editor:**—As health officer, I am frequently presented with the problem of whether or not to give rabies vaccine following rat bites. There is considerable difference in opinion among health officers, epidemiologists and veterinarians as to whether or not this prophylactic measure should be used. In the East St. Louis area, we have not had a reported positive dog head in almost two years. In the past, my policy has been to give rabies vaccine to all rat bite patients referred by their family physicians for such treatment. In many cases, especially in small babies, I have been reluctant to do so, but I would not desist because of legal complications. Recently, a physician called concerning this matter. A child had been bitten on the finger by a rat. I told him that the danger of complications in the indescriminate use of rabies vaccine must be weighed against the possibility of rabies resulting from a rat bite. I feel the chances of rabies developing in this instance are less. Is my reasoning sound?

C. F. Leonard, M.D., East St. Louis, Ill.

[This inquiry was referred to two authorities, whose respective replies follow.—Ed.]

Answer.—As rat bites do not cause rabies there is no reason for using rabies vaccine in such cases. It is well known that rabies vaccine by itself in some cases may cause undesirable reactions.

Answer.—Rats are susceptible to rabies and theoretically constitute a possible reservoir and source of infection for man. Actual experience in this country has shown that the number of rats proved to be infected with rabies has been minimal. In advising physicians concerning rabies immunization after rat bites, the same criteria should be applied as applies to bites of any other animals, such as dogs; namely, if the biting rat is caught and can be observed, vaccine may be withheld as long as the rat does not show symptoms of rabies within a period of two weeks' observation. If the rat gets away or even if apprehended and the bite has been particularly severe, in a geographic area where there is known to be an active reservoir of rabies in other animals, then it would seem necessary to go ahead and immunize on the possibility that the biting rat may have had rabies infection. You are correct in weighing the possibilities of a patient's having a serious reaction to the rabies vaccine against the chances of the person's having actually been exposed to rabies.

## PREVENTING BRUCELLOSIS

*To the Editor:*—I am making a special study of brucellosis for this community and would like an official statement regarding specifc measures recommended for control and eventual abolition of this disease.

John J. Clancy, M.D., Hartford, Conn.

Answer.—The control and eventual eradication of brucellosis is dependent on available epidemiologic knowledge of the disease. The reservoir of brucellosis is in domestic animals, especially cattle, hogs and goats. The disease is not transmitted from human being to human being except under extremely rare conditions, such as the establishment of an infection in utero or the transmission of Brucella to a nursing infant through the milk of an infected mother. Brucella organisms are shed in the milk of infected cattle and goats, and, therefore, the disease is contracted by human beings through the ingestion of raw milk or products of milk such as cheese and butter prepared from unpasteurized milk. One method of controlling the disease in human beings, then, is to have all milk pasteurized for human consumption. A second method of contracting the disease is through dermal contact with infected material such as animal tissues, secretions and excretions. In this manner, the disease is occupational and may affect farmers, livestock producers, meat-packing plant employees and veterinarians. There are no practical procedures for preventing brucellosis in human beings under these conditions except by eradicating the disease at its source. The disease can be eliminated in cattle by vaccination of calves and by eradicating from a herd animals which have positive agglutination reactions. The eradication of brucellosis in swine poses a more difficult problem in that the blood test is not so reliable in this species. Brucellosis in goats constitutes a problem in some sections of the country, particularly the Southwestern states.

## ULTRAVIOLET LIGHT IN INDUSTRY

*To the Editor:*—A manufacturer of electric sheets asks whether there would be any harm in the use of mercury vapor, 100 watts, Westinghouse or Hanovia ultraviolet lamps. Lines have to be made on the sheets to guide the workers sewing on the electric wire. These lines often show. He has an ink which is visible only in ultraviolet light. What, if any, harmful effects would there be to the skin or body of a worker exposed to this light, even though exposure is only to hands, eight hours a day, 40 hours a week?

M. J. Frank, M.D., Beacon, N. Y.

Answer.—Therapeutic ultraviolet lamps are not suited for the purpose mentioned. Other types emit rays of such Angstrom length as largely to avoid any significant damage to the skin or eyes. Among others, Hanovia, General Electric and Westinghouse manufacture such lamps in various sizes and with as low a watt consumption as 10. It is possible that long exposure may lead to skin pigmentation but without erythema. Likewise, the need may arise for the wearing of a light eye shield or goggles. With properly chosen lamps, the real physiologic problem is not related to ultraviolet damage but to eye strain. The types of lamps mentioned emit little visible light and properly are termed "black light lamps." Since fluorescence best shows up in darkness, a visual problem arises from the lack of proper illumination. However, suitable arrangement may be devised so that adequate general lighting may exist, together with sharply localized ultraviolet light such as will sufficiently activate the phosphor. Since the number of fluorescing substances is high, the choices should be such as to provide fluorescence even when visible light is nearby. In general, it is the intent to state that with proper choice of lamps this sewing operation may be carried out without the prospect of any significant harmful action on skin or eyes.

## ANATOMIC ASYMMETRY

*To the Editor:*—The question recently arose in a consultation on an industrial case as to whether the measurements of the left leg were larger than the right leg in a perfectly normal person without any antecedent disease in the legs. Please supply information on this question.

David C. James, M.D., Phoenix, Ariz.

Answer.—The question of bilateral asymmetry of the human body has been reviewed by George Halperin in an article published in the *Archives of Internal Medicine* (48:676-682, 1931). It appears that as a result of exact measurements taken from a great number of cadavers and living subjects it has been established that the two halves of the body in the human species are never symmetric. Among other asymmetries it is an accepted fact that the left leg is more often longer and stronger than the right. That is probably the reason why soldiers begin their marching with the left leg and why jumpers usually employ the left leg for a kickoff. Cox (Cox, W. C.: On the Want of Asymmetry in the Length of Opposite Sides of Persons Who Have Never Been the Subject of Disease or Injury to Their Lower Extremities, *Am. J. M. Sc.* **69**:438, 1875) found that in living subjects the difference in the length of the lower extremities amounted to ⅛ to ⅞ inch (0.32 to 2.23 cm.) and that the left extremity was more often the longest.

## INTRADERMAL TYPHOID IMMUNIZATION

*To the Editor:*—I would like to know the number of intradermal typhoid vaccine injections (0.1 cc.) that are equivalent to the routine immunization of three subcutaneous injections. Also, what is the interval between the intradermal injections?

J. B. Taylor, M.D., Carbondale, Ill.

Answer.—Two recommendations, which vary somewhat, have been made for typhoid immunization by means of intracutaneous injections of antityphoid vaccine. The first of these calls for four intracutaneous injections as follows: 0.05, 0.1, 0.15 and 0.2 cc. The second method consists of only three injections of 0.1 cc. each. It is claimed that the latter dosage affords satisfactory protection. With either procedure, the interval between injections is one week. It is likely that a better antigenic response can be accomplished if injections are made two weeks apart.

## ALCOHOL INTOLERANCE

*To the Editor:*—In Queries and Minor Notes, The Journal, March 26, page 896, the statement that alcohol intolerance may be a sign of developing delirium tremens or Korsacow's syndrome is somewhat unsatisfying. I have seen this symptom of a developing intolerance to alcohol often in formerly moderate or heavy drinkers and these were definitely not in the early stages of an alcoholic psychosis. On the contrary, I have regarded the symptom on the basis of the known dynamics of the cases as a functional symptom, the purpose of which is to protect the patient from a growing sense of dependence on alcohol. In cases I have observed the symptom took place as one of the incipient personality changes in the development of a neurosis. I would be glad to hear whether any of your readers have noticed this phenomenon, as I do not recall ever seeing it in the literature. The development of an alcohol intolerance has been mentioned as occurring in soldiers with brain injury as a result of blast and has even been offered as a differential diagnostic sign to distinguish this from the ordinary combat traumatic neurosis. However, I do not believe that this is so, as I have seen the symptom too often in psychoneurotic persons who showed no history or symptoms of injury. I agree with your authority that such a patient is lucky that the "bell tinkles before it tolls."

R. E. Peck, M.D., Brooklyn.

## WARTS

*To the Editor:*—Please refer to Queries and Minor Notes, The Journal of February 26, page 615, under the heading "Warts."

In the "long list of remedies recommended for the treatment of warts," dosage with vitamin A, 100,000 units per day for six to twelve weeks, should be mentioned. In the particular case cited a thorough trial of vitamin A therapy is indicated. In many such cases the results have been spectacularly good.

Being a radiologist, I have for many years been interested in a study of the deleterious influence of irradiation on tissue, and I feel that anything which tends to make roentgen or radium therapy unnecessary, especially in benign conditions and when the patient is young, deserves a great deal of emphasis. Irradiation of warts has caused harm in some persons, and even where the harm is not visible to the casual observer it is nevertheless present in a form which can be visualized histologically. In 60 to 80 per cent of all cases, warts disappear as a result of the ingestion of 100,000 units of vitamin A per day.

# THE USE OF ESTROGENS AND ANDROGENS IN ADVANCED MAMMARY CANCER

## Clinical and Laboratory Study of One Hundred and Five Female Patients

F. E. ADAIR, M.D.
R. C. MELLORS, M.D.
J. H. FARROW, M.D.
H. Q. WOODARD, Ph.D.
G. C. ESCHER, M.D.
and
J. A. URBAN, M.D.
New York

Estrogens and androgens were used clinically in 105 female patients with either primary or recurrent inoperable mammary cancer who were, with few exceptions, ambulatory when first treated. Of this group, 55 have died of cancer and all survivors have evidence of persistent disease. Hence, the results were analyzed on the basis of temporary objective and subjective changes which occurred during one to twenty-four months' observation. In addition, various laboratory studies were made and analyzed in an attempt to evaluate the clinical changes which were observed. For various reasons, 44 patients were treated for less than one month. Since data on these patients were incomplete, they were excluded from this report.

### REVIEW OF THE LITERATURE

Both Ulrich[1] and Loeser[2] in 1939 drew attention to the possible usefulness of androgens in the treatment of mammary cancer in the human female. Farrow and Woodard[3] in 1942 observed subjective, but no objective, improvement in about half of 33 patients receiving androgens. Of 3 cases described by Fels[4] in 1944, one woman aged 34 had a diminution in the size of supraclavicular lymph nodes, an increase in calcification and a decrease in the size of osseous metastases following the administration of testosterone. Adair and Herrmann[5] in 1946 found objective evidence of improvement in 4 of 11 patients treated with testosterone propionate. Three patients had roentgenographic evidence of improvement in osseous metastases. One patient had a decrease in the size of the primary tumor and of the lymph node metastases. Since 1946, additional reports of the use of androgens in advanced mammary cancer have appeared in the literature.[6] In addition, a report on the use of androgens and estrogens in mammary cancer has been issued by the Subcommittee on Steroids and Cancer, Therapeutic Trials Committee of the Council on Pharmacy and Chemistry of the American Medical Association.[7]

Haddow and others[8] in 1944 first described the use of the synthetic estrogens, diethylstilbestrol and triphenylchlorethylene in a variety of neoplastic diseases including carcinoma of the breast, bladder, rectum, skin and testes. In the same year the Section of Radiology of the Royal Society of Medicine[9] presented a discussion of synthetic estrogens used in cases of advanced mammary cancer. For the extension and the coordination of this work, the Royal Society of Medicine and the British Empire Cancer Campaign have established a Joint Scientific Committee on the Use of Estrogens in Cancer. In this country, reports of the use of estrogens in advanced mammary cancer have been given by Nathanson[10] and by Herrmann, Adair and Woodard.[11]

## CLINICAL MATERIAL AND ANATOMIC DISTRIBUTION OF METASTASES

*Age Distribution.*—Of the 105 patients, 70 were treated by intramuscular injections of androgens and 35 were given estrogens. Radiotherapy was not given to any patient during the period of this study or within a reasonable period prior to the study. The age distribution and menopausal status of the subjects is shown in table 1. It is to be noted that the patients treated with estrogens were from two to thirty-two years postmenopausal, the average being twelve years.

Table 1.—*Age Distribution and Treatment in One Hundred and Five Patients with Advanced Mammary Carcinoma Receiving Endocrine Therapy for One Month or More*

| Age | Androgen (70 Patients) |  | Estrogen (35 Patients) |
|---|---|---|---|
|  | Pre-menopausal | Post-menopausal | Post-menopausal |
| 20 to 30 | 2 | 0 | 0 |
| 30 to 40 | 10 | 4 | 0 |
| 40 to 50 | 13 | 9 | 1 |
| 50 to 60 | 3 | 22 | 14 |
| 60 to 70 | 1 | 6 | 15 |
| 70 on | 0 | 0 | 5 |
| Totals | 29 | 41 | 35 |

*Distribution of Metastases.*—The anatomic distribution of metastases in the total group at the time of admission to this study is given in table 2. Because of special interest in skeletal metastases the sites and the incidences are given in detail. All other metastatic sites, including the breast, are grouped under soft tissues.

Table 2.—*Distribution of Metastases in One Hundred and Five Patients with Advanced Mammary Carcinoma Receiving Endocrine Therapy for One Month or More*

| Location of Metastases | Incidence: Recurrent Inoperable * | Incidence: Primary Inoperable † |
|---|---|---|
| Bone | 41 | 11 |
| Pelvis | 25 | 8 |
| Lumbar vertebrae | 22 | 6 |
| Femurs | 19 | 7 |
| Ribs | 17 | 7 |
| Dorsal vertebrae | 13 | 0 |
| Skull | 8 | 2 |
| Cervical vertebrae | 3 | 7 |
| Mandible | 2 | 0 |
| Scapulas | 2 | 2 |
| Humeri | 1 | 1 |
| Radiuses | 2 | 0 |
| Sternum | 2 | 0 |
| Clavicles | 1 | 1 |
| Soft tissue | 56 | 33 |
| Breast (primary lesion) | 0 | 33 |
| Skin | 33 | 26 |
| Lymph nodes | 29 | 26 |
| Pleurae | 16 | 6 |
| Lungs | 13 | 4 |
| Liver | 7 | 1 |
| Breast (opposite) | 6 | 10 |
| Mediastinum | 3 | 0 |
| Uterus | 1 | 0 |
| Gallbladder | 1 | 0 |
| Colon | 1 | 0 |

* Seventy-two cases.
† Thirty-three cases.

Of the total, 72 patients had undergone at an antecedent date a radical mastectomy, with or without postoperative roentgen therapy, and were classified as having recurrent inoperable mammary cancer. There were ninety-seven anatomic sites of metastases in the group with about equal distribution between bone (forty-one sites) and the soft tissues (fifty-six sites). The bones which were most frequently involved were the pelvic girdle, lumbar vertebrae, femurs, ribs and dorsal vertebrae. The most frequent sites of metastases in the soft tissues were the skin, lymph nodes, pleurae and lungs. Cutaneous involvement occurred either by local recurrence or by metastasis.

Thirty-three patients had advanced mammary cancer without an antecedent operation and were classified as having primary inoperable mammary cancer. In addition to the primary mammary lesion, there were 11 incidences of metastases in bone, 26 in lymph nodes, 26 in skin and 10 in the opposite breast.

## CLINICAL RESULTS WITH ANDROGENS

*Dose.*—Synthetic androgenic substance was administered regularly as testosterone propionate,[12] 100 mg. intramuscularly three times a week, to 70 patients for periods of one month or longer. As shown in chart 1, the number of patients who continued therapy decreased rapidly, so that 50 per cent received treatment for less than five months. The maximum cumulative dose was 19,600 mg. of testosterone propionate.

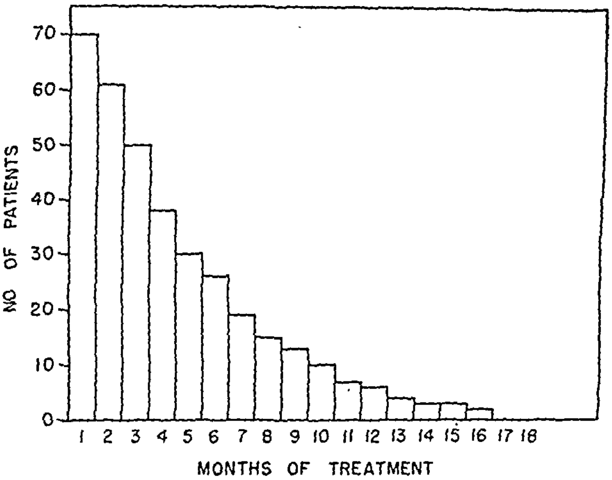

Chart 1.—Number of patients continuing on androgen therapy (testosterone propionate 300 mg. a week intramuscularly) for one month or more.

*Objective Changes.*—A critical appraisal of the clinical results, based on objective changes, is shown in table 3. The term objective improvement in osseous metastases is applied to radiographic changes, such as calcification of osteolytic lesions, apparent reformation of bone and healing of pathologic fractures, without an increase in the size or number of the lesions. In histologically confirmed lesions of soft tissue, such as the breast, skin or lymph nodes, objective improvement is indicated by a significant measurable decrease in the size of the lesion and by healing of ulcers. Favorable changes in histologically proved metastases in the pleurae, liver and uterus are based on clinical, radiographic and laboratory data which apply to the individual patient.

By these criteria objective improvement, as recorded in table 3, occurred in 19 per cent of 48 patients with skeletal metastases. No change was present in 23 per cent, while there was definite evidence of progression at an apparently unaltered rate in 39 per cent. The data were inconclusive in 19 per cent. Specific sites of skeletal improvement had a wide variation. Thus, of 29 lesions involving the bones of the pelvis 7 were improved, while only one of 23 involving the femurs responded favorably.

---

[12] Supplied by the Schering Corporation as oreton.®

Objective improvement occurred in 15 per cent of 54 patients with soft tissue metastases. No change was present in 26 per cent, while there was progression at an apparently unaltered rate in 48 per cent. The data were inconclusive in 11 per cent. In 4 of 27 incidences of cutaneous involvement significant decreases in size occurred, but none of 14 mammary lesions was improved. Although the clinical evaluation of metastases in lymph nodes is inaccurate, attempts were made to determine measurable changes in palpable lymph nodes. Decreases in size of nodes were not uncommon. However, of 10 nodes which were proved by aspiration biopsy to contain metastatic cancer, 3 underwent a significant decrease in size. Improvement, admittedly difficult to assess, occurred on occasion in the pleurae, liver and uterus.

Of particular interest was the appearance of additional lesions during the time of treatment. Thus, osseous metastases developed in 4 of 16 patients who had lesions only in soft tissue prior to androgen therapy. Also, metastases appeared in soft tissues in 5 of 22 patients who had, prior to treatment, only lesions in bone. In a few patients with multiple skeletal metastases, objective improvement could be demonstrated in one site while other lesions appeared to progress.

TABLE 3.—*Distribution of Metastases and Occurrence of Objective Improvement in Seventy Patients Receiving Androgens for One Month or More*

| Location of Metastases | Incidence | Objective Improvement |
|---|---|---|
| Bone | 48 | 9 |
| Pelvis | 29 | 7 |
| Lumbar vertebrae | 27 | 3 |
| Femurs | 23 | 1 |
| Ribs | 23 | 4 |
| Dorsal vertebrae | 19 | 1 |
| Skull | 10 | 0 |
| Humeri | 4 | 0 |
| Scapulas | 3 | 0 |
| Cervical vertebrae | 3 | 1 |

| Uterus | 1 | 1 |

* Of thirteen biopsies, ten were positive for metastatic cancer.

Radiographic Changes in Bone: A classification has been made of the initial radiographic appearance (osteolytic, osteoblastic and mixed) of the osseous metastases in 48 patients and of the change in the radiodensity and in the total area of osseous metastases following treatment with androgens (table 4). Since the data were not appreciably different in the premenopausal group (12 patients) and in the postmenopausal group (36 patients), the series was analyzed as a whole. The initial appearance of the osseous metastases was predominantly osteolytic in 52 per cent, osteoblastic in 13 per cent and mixed osteolytic and osteoblastic in 35 per cent of the cases. Following treatment, there was an increase in radiodensity with no change, except an occasional decrease, in the total area of involvement in 19 per cent of the cases. The initial classification in this group was either osteolytic or mixed metastases with approximately an equivalent incidence. In 6 per cent of the cases there was both an increase in the radiodensity and an increase in the total area of involvement. In 44 per cent of the cases there was a decrease in the density and an increase in the area of involvement. In 15 per cent there was no change in the density or in the size of the lesion. The data were inconclusive as to the status of the radiographic changes in 16 per cent.

TABLE 4.—*The Initial Radiographic Classification of Osseous Metastases in Forty-Eight Patients and the Changes During Treatment with Androgens*

| | | Radiographic Density | | | | | | |
|---|---|---|---|---|---|---|---|---|
| | | Increase | | Decrease | | No Changes | | |
| Classification | Cases | No Increase Area | Increase Area | No Increase Area | Increase Area | No Increase Area | Increase Area | Inconclusive Data |
| Osteolytic | 25 | 5 | 0 | 0 | 10 | 7 | 0 | 3 |
| Osteoblastic | 6 | 0 | 1 | 0 | 1 | 0 | 0 | 4 |
| Mixed | 17 | 4 | 2 | 0 | 10 | 0 | 0 | 1 |
| Total | 48 | 9 | 3 | 0 | 21 | 7 | 0 | 8 |

*Total Dose of Androgens with Duration of Improvement.*—The total dose of testosterone propionate at the time of objective improvement and the duration of the improvement in 14 of 70 patients receiving the agent are given in table 5. The total dose at the time of improvement varied from 500 to 11,400 mg. of testosterone propionate. Approximately half of the doses were less than or equal to 3,000 mg. The

* Improvement continues at date of this writing.

objective improvement extended over a range of two to eleven months and continued in about half of the patients for four months or longer. Approximately the same incidence of objective improvement occurred in the premenopausal group, 17 per cent, as in the postmenopausal group, 22 per cent.

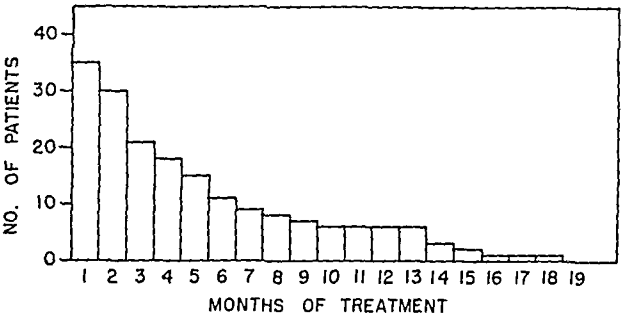

Chart 2.—Number of patients continuing on estrogen therapy for one month or more.

*Symptomatic Changes.*—The initial symptoms and the symptomatic improvement in 70 patients receiving androgens are shown in table 6. The most impressive effect was the relief of pain, which was temporarily effected in 44 of 58 patients with that initial complaint. Anorexia, general malaise and dyspnea were characteristically improved. It is clinically significant that many patients were symptomatically improved while at the same time the disease was progressive. The physical status of all patients prior to treatment was such that half of them were unable either to work or to care for their personal needs. Following treatment, the average improvement in this group was such that a majority were able to carry on essentially normal physical activity or to be gainfully employed.

## CLINICAL RESULTS WITH ESTROGENS

*Dose.*—Estrogenic substance was administered orally as diethylstilbestrol,[13] 5 mg. three times a day, to 20 patients; as ethinyl estradiol,[14] 1 mg. three times a day, to 10 patients; as estrone sulfate,[15] 10 mg. three times a day, to 4 patients. Estradiol benzoate,[16] 3.32 mg. intramuscularly three times a week, was given to 1 patient.

Table 6.—*Initial Symptoms and Incidence of Symptomatic Improvement in Seventy Patients Receiving Androgens*

| Symptom | Number of Patients with Symptom | Number of Patients with Symptomatic Improvement |
|---|---|---|
| Pain | 58 | 44 |
| Anorexia | 29 | 21 |
| General malaise | 24 | 20 |
| Dyspnea | 24 | 20 |
| Nausea | 8 | 6 |
| Cough | 3 | 1 |
| Headache | 3 | 3 |

As shown in chart 2, the number of patients that continued therapy decreased rapidly, so that 50 per cent received treatment for less than five months. The maximum cumulative dose of diethylstilbestrol was 8,910 mg.; of ethinyl estradiol, 1,198 mg., and of estrone sulfate, 3,780 mg.

*Objective Changes.*—Criteria for the estimation of objective improvement were the same as those previously given for the evaluation of those patients given androgens. The distribution of involvement in soft tissue (35 patients) and in bone (4 patients) and the incidence of objective improvement in the various sites are given in table 7. Objective improvement occurred in 23 per cent of 35 patients with involvement of soft tissue. The sites of improvement were skin, lymph nodes, primary mammary carcinoma and pleurae. Favorable effects were not demonstrated in osseous metastases. The remainder of metastases in soft tissue underwent no change in 28 per cent and progressed at a natural rate in 42 per cent. In 6 per cent the data were inconclusive. In 1 case there was an apparently accelerated growth. In 3 of the 31 patients who had lesions originally in soft tissue alone there developed metastases to bone during estrogen therapy.

*Total Dose with Duration of Improvement.*—The preparation and the total dose of estrogen at the time of objective improvement and the duration of improvement in 8 of 35 patients are given in table 8. Seven of the 8 patients who were improved received diethylstilbestrol and 1 received ethinyl estradiol. The total dose at the time of improvement varied from 210 to 1,470 mg. diethylstilbestrol, with approximately one half of the doses equal to or less than 630 mg. The objective improvement extended over a range of two to seventeen months and continued in approximately one half of the patients for seven months or longer. These patients were in the sixth to the eighth decades of life and were two to twenty-nine years past the menopause.

Table 7.—*Distribution of Metastases and Occurrence of Objective Improvement in Thirty-Five Patients Receiving Estrogens for One Month or More*

| Location of Metastases | Incidence | Objective Improvement |
|---|---|---|
| Soft tissue | 35 | 8 |
| Skin | 33 | 6 |
| Breast (primary lesion) | 23 | 1 |
| Lymph nodes | 22 | 2 |
| Breast (opposite) | 8 | 0 |
| Pleurae | 8 | 1 |
| Lungs | 6 | 0 |
| Liver | 1 | 0 |
| Mediastinum | 1 | 0 |
| Bone | 4 | 0 |
| Pelvis | 2 | 0 |
| Lumbar vertebrae | 2 | 0 |
| Femurs | 2 | 0 |
| Ribs | 2 | 0 |
| Scapulas | 1 | 0 |
| Sternum | 1 | 0 |
| Dorsal vertebrae | 1 | 0 |
| Clavicles | 1 | 0 |

*Symptomatic Changes.*—The presenting symptoms and the incidence of symptomatic improvement in 35 patients receiving estrogens are given in table 9. Pain, the commonest initial symptom, was significantly relieved in 11 of 18 patients with that complaint. Dyspnea, anorexia and general malaise were appreciably improved. The physical status of all patients prior to treatment was such that one fourth of them were unable to work or to care for their personal needs. After treatment the average improvement in this group was such that most of them were able to carry on essentially normal physical activity.

[14] The Schering Corporation supplied the ethinyl estradiol as estinyl.®

[15] Ayerst, McKenna & Harrison, Ltd., supplied the estrone sulfate as premarin.®

[16] The Schering Corporation supplied estradiol benzoate as progynon-b.®

### SIDE EFFECTS AFTER ADMINISTRATION OF ESTROGENS AND ANDROGENS

The incidence of the more noticeable side effects of estrogenic and androgenic therapy are given in table 10. In some patients after the administration of androgen the edema of the lower extremities, deepened voice, increased libido, hirsutism and acne were extreme. Vaginal bleeding, which occurred in 6 of 35 patients receiving estrogen therapy, was in 4 instances due to withdrawal of estrogen rather than to continuous medication. Nausea unaccompanied by vomiting persisted in 9 patients who received estrogen, but not to the extent that treatment was interrupted. In a few instances the failure to retain estrogen because of nausea and vomiting excluded patients from the study.

Corrective measures for the undesirable side effects were generally limited in usefulness. It was possible, however, to control the peripheral edema in a majority of patients by placing them on a 0.5 Gm. sodium diet, with or without the use of mercurial diuretics. This was necessary in a few elderly patients with a poor cardiac reserve.

TABLE 8.—*Total Dose of Estrogen at Time of Objective Improvement and Duration of Objective Improvement in Eight Patients*

| Patient | Age | Post-menopausal, Yr. | Site of Improvement | Total Dose at Time of Improvement, Mg. | Months of Improvement |
|---|---|---|---|---|---|
| L. M. | 71 | 21 | Skin | 720* | 17 |
| A. K. | 73 | 27 | Skin | 420* | 17† |
| | | | Breast (primary) | 1,260* | 15† |
| E. C. | 58 | 20 | Skin | 210* | 8 |
| B. S. | 56 | 6 | Skin | 1,470* | 5 |
| L. E. | 62 | 2 | Lymph node | 1,050* | 7† |

* Diethylstilbestrol.
† Improvement continues at date of this writing.
‡ Ethinyl estradiol.

There was neither clinical nor laboratory evidence in any case that either the primary or the metastatic mammary cancer had taken an accelerated course because of the androgen therapy. There was in 1 patient, aged 49 and five years past the menopause, an apparent acceleration of growth of cutaneous recurrences of mammary cancer after treatment with estrogens.

### LABORATORY STUDIES

*Blood Chemical Studies.*—In order to clarify the effect of endocrine therapy on skeletal metastases, observations were made of the calcium, inorganic phosphorus, and alkaline phosphatase in the serum of patients both with and without osseous lesions at intervals varying from two weeks to two months. Phosphorus and phosphatase were determined by Bodansky's[17] method. In normal adults the values for alkaline phosphatase found in this laboratory ranged from 1.5 to 5 units per hundred cubic centimeters. Total serum calcium was determined by the method of Kramer and Tisdale,[18] the normal range being 10 to 11.5 mg. per hundred cubic centimeters.

Because of the variability in the response of patients to endocrine therapy, it was considered important, in evaluating the changes observed, to use as large a series as possible. Hence, the following summary is based on observations both on patients in the present study and on comparable patients in the series previously reported by Hermann and co-workers.[19] About one third of the cases are from the earlier work. No patients were included who had jaundice or clearcut evidence of hepatic dysfunction, or who had recently received vitamin D, aluminum hydroxide gels or other agents likely to alter the metabolism of bone.

TABLE 9.—*Initial Symptoms and Incidence of Symptomatic Improvement in Thirty-Five Patients Receiving Estrogens*

| Symptom | Number of Patients with Symptom | Number of Patients with Symptomatic Improvement |
|---|---|---|
| Pain | 18 | 11 |
| Dyspnea | 16 | 8 |
| Anorexia | 10 | 7 |
| General malaise | 9 | 3 |
| Nausea | 2 | 0 |
| Cough | 1 | 0 |
| Headache | 1 | 1 |

Satisfactory pretreatment observations of blood chemistry were available on 103 patients, of whom 56 had roentgenographic evidence of osseous metastases. In the patients without skeletal metastases the average values for calcium, phosphorus and alkaline phosphatase were almost identical with those for normal adults. Individual variations were slightly greater than normal. Thus, 4 patients had minor elevations in phosphatase, perhaps due to unrecognized dysfunction of the liver. One patient had a definite hypercalcemia (12 mg. per hundred cubic centimeters), but this was associated with a serum protein level of 8.4 Gm., so that part of the increase in total calcium was due to an increase in the protein-bound fraction. In general, it was evident that the presence of active mammary cancer in itself had no direct effect on the calcium, phosphorus or alkaline phosphatase values of the serum.

TABLE 10.—*Physiologic and Other Changes in Patients Receiving Endocrine Therapy*

| | Androgen | Estrogen |
|---|---|---|
| Number of patients | 70 | 35 |
| Increased weight | 47 | 18 |

[19] Footnotes 6 b and 11.

In the patients with osseous metastases the average values for the calcium and alkaline phosphatase of the serum were above normal. There was a definite elevation of the alkaline phosphatase level in 26 patients, or 46 per cent of the total, although extremely high readings were not found, and only 4 patients had values above 10 units per hundred cubic centimeters. Definite hypercalcemia was found in 13, or 23 per cent, of the patients with osseous metastases, the highest reading being 15.5 mg. per hundred cubic centimeters. Unusual elevations in calcium and phosphatase values were not observed simultaneously in the same patient, but smaller changes frequently occurred together.

In the absence of hepatic disease an increase in the serum alkaline phosphatase indicates an increase in osteoblastic activity. Elevations in the total serum calcium may occur after the administration of large amounts of vitamin D or its analogues, in the presence of pronounced hyperproteinemia, in primary or secondary hyperparathyroidism even without osseous disease and possibly in some other uncommon metabolic disturbances. If these are excluded, hypercalcemia in a patient with disease of the bone indicates that osteolysis is proceeding so rapidly as to exceed the capacity of the kidney to excrete calcium. In the patients in this series the metastatic lesions in the bones were predominantly osteolytic, although areas of new bone formation could also be found in many cases. A study of the abnormalities in the chemistry of the blood of our patients prior to the institution of treatment makes it appear that the presence of metastatic deposits of mammary cancer in bone stimulates an osteoblastic response in about half of the cases. When the osteoblastic response is lacking or inadequate, osteolysis occurs. When the metastatic tumor in the bone is growing rapidly, osteolysis may be sufficiently intense to cause hypercalcemia, especially if the opposing response of the osteoblasts is feeble.

Satisfactory observations of serum calcium, phosphorus and alkaline phosphatase values were available for one or more months following the institution of endocrine therapy in 92 patients. Of these the number with osseous metastases treated with ethinyl estradiol and the numbers with or without osseous metastases treated with diethylstilbestrol were too small to summarize. The observations on 48 patients with osseous metastases and 15 patients without osseous metastases who were treated with testosterone propionate and on 18 patients without osseous metastases who were treated with ethinyl estradiol are summarized in table 11.

With one exception, significant changes in the calcium and alkaline phosphatase of the serum of patients without osseous metastases were not observed during the first three months of therapy with either testosterone propionate or ethinyl estradiol. The exception was a small elevation in phosphatase which occurred six weeks after the institution of ethinyl estradiol therapy. The minor fluctuations in calcium which sometimes occurred seemed to be correlated with changes in the concentration of serum protein. It appeared that these endocrine substances in the doses employed seldom if ever had a direct effect on the serum calcium and alkaline phosphatase.

There was a rise in the serum alkaline phosphatase in 30, or 63 per cent, of the 48 patients with osseous metastases during the first three months of treatment with testosterone propionate. The rise was often associated with an increase in the degree of osteoplasia of the bone lesions, but was not closely correlated with evidence of either healing or progression of the lesions. In the patients who were followed for longer periods there was a tendency for the serum alkaline phosphatase to revert to pretreatment levels after about four months of continued testosterone propionate therapy, regardless of whether or not the disease showed renewed activity. The possible significance of this rise in serum alkaline phosphatase during the first three months of various types of endocrine therapy has been discussed by one of us elsewhere.[20] Results in the present study tend to confirm our previous belief that some types of endocrine therapy stimulate osteoblastic activity in injured bone. Such stimulation is not directly related to the response of the metastatic tumor. It is of clinical significance in that it tends to check osteolysis and reduce the danger of pathologic fracture.

Of the 21 patients with osseous metastases who showed a pretreatment hypercalcemia, 15, or 71 per cent, showed a significant drop in serum calcium during the first three months of treatment with testosterone propionate. This fall in serum calcium was usually associated with evidence of a decrease in the rate of osteolysis, either because osteolytic lesions ceased to grow or because they were converted to osteoplastic ones. In this series no patient with osseous metastases was seen in whom there was definite evidence that the institution of testosterone propionate therapy caused an exacerbation of the disease with accompanying hypercalcemia such as occurred in the 3 patients described in a previous paper.[3]

There was a significant fall in the serum inorganic phosphorus in 45, or 56 per cent, of the 81 patients treated with either testosterone propionate or ethinyl estradiol. Patients with osteolytic metastases occasionally have a hyperphosphatemia for the same reason that they exhibit hypercalcemia; that is, because large amounts of calcium and inorganic phosphorus enter the circulation from the bones. In such patients a fall in serum phosphorus during endocrine therapy might be due solely to a reduction in the rate of osteolysis. In this series, however, patients without osseous metastases manifested a drop in serum phosphorus almost as frequently as those with osseous metastases. The fall in phosphorus is therefore not due solely to an effect of treatment on metastatic tumor. Such a fall in phosphorus has been reported by one of us [20] to occur in patients with carcinoma of the prostate during treatment with diethylstilbestrol, but not after surgical castration. Nathanson [21] has observed it in women during diethylstilbestrol therapy. At present there are not sufficient data to show whether there is a correlation between the fall in serum phosphorus and the clinical response during endocrine therapy.

[20] Woodard, H. Q., and Dean, A. L.: The Significance of Phosphatase Findings in Carcinoma of the Prostate, J. Urol. 57: 158, 1947.

*Histologic and Histochemical Studies.*—Primary Mammary Cancer: The histologic classification of the mammary carcinoma in the 105 cases was as follows: carcinoma of mammary ducts, 59; carcinoma of the mammary lobules, 1; carcinoma simplex of the nipple, 1; sweat gland carcinoma, 1; metastatic mammary carcinoma, 33, and unclassified mammary carcinoma, 10.

Tissue for histologic and histochemical study was taken from the primary mammary carcinoma and from representative metastatic lesions in the skin and the lymph nodes and, in special instances, in the uterus, the liver, the bones, the pleurae and the peritoneum. Aside from routine procedures, the staining technics of Giemsa, Unna-Pappenheim and Van Gieson were applied.[22] In addition, a histochemical investigation was made of the distribution of three constituents which, under centain conditions, may be important in cell growth: nucleic acids,[23] high polymeric sulfuric acid esthers [24] and phosphatase enzymes.[25] In all, 74 cases were studied. Twenty had had satisfactory studies both prior to and during treatment, and in 8 of these, observations were made on regressing cutaneous metastases. Within the limits of this small series two changes, which have seldom occurred to an unusual degree, were as follows: (1) degenerative changes in the nucleus and the cytoplasm of the cancer cells and (2) fibroblastic proliferation and sclerosis of the connective tissue. The results were not conclusive in determining whether the changes differed in degree, if not in kind, from those which may occur spontaneously.

Exfoliating Vaginal Mucosa: Cytologic studies, using the method of Papanicolaou,[26] have been made of the vaginal smears in practically all instances prior to treatment and at weekly or biweekly intervals thereafter. The smears have been classified according to the ratios of the following epithelial cell types: acidophilic superficial squamous; basophilic superficial squamous, and intermediate and outer basal types. In the postmenopausal group, prior to treatment, 60 per cent of the smears contained nearly all basophilic squamous cells, 14 per cent had some acidophilic squamous cells and 26 per cent had some basal type cells. In the premenopausal group prior to treatment, 62 per cent of the smears contained nearly all basophilic squamous cells and 38 per cent of the smears had some acidophilic squamous cells.

After one month of treatment with testosterone propionate, the smears of both the premenopausal group and the postmenopausal group contained relatively more of the basal cells and few acidophilic squamous cells. There was little change in the second month of treatment, but there was a tendency toward a more frequent occurrence of acidophilic squamous cells. In individual cases the increased acidophilia in the smear became apparent during subsequent months of treatment, but this was not evident in the distributional analysis of the group as a whole.

After one month of treatment with estrogens the smears (all from postmenopausal women) contained relatively more of the acidophilic squamous cells, but there was no preponderance of smears with all acidophilic squamous cells. There was a rare smear with basal cells. There was little change in the second month of treatment. In individual cases a tendency toward increased basophilia in the smear became apparent during subsequent months of treatment, but this was not evident in the distributional analysis of the group as a whole.

There was no obvious relation between the initial cytologic appearance of the smear or the subsequent changes and the presence or absence of hepatic dysfunction as revealed in a study of 37 of these patients.

Cervical and Uterine Mucosa: A histochemical study (to be published elsewhere) was made of the glycogen content (Best's carmine method) [22] and the alkaline phosphatase activity (Gomori's method) [25a] in the cervical biopsies of 74 patients and in the endometrial curettings of 51 patients. In the stratified squamous epithelium of the cervix, the phosphatase activity, which was negligible, did not change whereas the cytoplasmic glycogen content either increased or remained elevated in one half of the cases after either androgen or estrogen therapy. In the glandular epithelium of the endometrium, the glycogen content did not change in either case, whereas the cytoplasmic phosphatase activity was slightly increased after the administration of estrogens.[27]

*Studies of Hepatic Function.*—The results of a study of the hepatic function (serum bilirubin, sulfobromophthalein sodium excretion, hippuric acid synthesis, thymol turbidity and cephalin flocculation) in 37 patients in this group, 6 of whom presented clinical evidence of hepatic disease, have been recently reported by Tagnon and Trunnell.[28]

Fifteen patients, or 41 per cent, had diminished hepatic function in two or more tests. For comparison, similar tests were made on 27 patients with primary operable mammary carcinoma and 27 apparently normal women of comparable ages. Six patients, or 21 per cent, of each group had abnormal values in two or more tests.

*Hemoglobin.*—The hemoglobin concentration of the peripheral blood in 15 patients with metastases to bone or soft tissue, after androgen therapy for an average of seven months, increased from an initial value of 12.6 Gm. to a value of 15.9 Gm. per hundred cubic centimeters, an average increase of 26 per cent. In a third of these cases the average increase was 40 per cent or more. In 2 patients the increment was more than 100 per cent, and in 2 patients the hemoglobin concentration rose to 19.7 Gm. per hundred cubic centimeters.

*Terminal Observations.*—Of 105 reported cases, 55 have terminated in death. Analysis of the immediate cause of death revealed that metastatic cancer was directly responsible in 34 (62 per cent), noncancerous systemic disease in 14 (25 per cent) and undetermined causes in 7 (13 per cent). Postmortem examinations were performed in 17 instances.[29] Active mammary carcinoma was found in every case. Areas of metastases determined clinically were all confirmed by the necropsy and, in addition, clinically undiagnosed areas of metastases were found in all cases. At necropsy the distribution and the incidence of the three most common extraskeletal metastases were as follows: pulmonary, 82 per cent; hepatic, 82 per cent, and cerebral, 41 per cent. Skeletal metastases were present in 82 per cent.

## SUMMARY AND CONCLUSION

*Clinical Results.*—One hundred and five female patients with advanced inoperable mammary carcinoma were treated with endocrine substances for one month or longer.

Testosterone propionate, 100 mg. intramuscularly three times a week, was given to 70 patients with metastases to bone, soft tissue or both. Objective improvement occurred in 19 per cent of 48 patients with skeletal metastases and in 15 per cent of 54 patients with extraskeletal metastases. The cumulative dose at the time of improvement varied from 500 to 11,400 mg. of testosterone propionate, and approximately half of these doses were less than, or equal to, 3,000 mg. The objective improvement extended over a range of two to eleven months and continued in one half of the patients for four months or longer. Approximately the same incidence of objective improvement occurred in the premenopausal group as in the postmenopausal group. The most impressive symptomatic effect was the relief of pain, which was temporarily effected in 44 of 58 patients with that initial complaint. It is clinically significant that many patients were symptomatically improved even though at the same time the disease was progressive.

Estrogenic substances (diethylstilbestrol, ethinyl estradiol and estrone sulfate) were given to 35 patients. Objective improvement occurred in 23 per cent of 35 patients with extraskeletal metastases. The sites of improvement were the skin, lymph nodes, primary mammary carcinoma and pleurae. No favorable effects were observed in osseous metastases. With diethylstilbestrol the cumulative dose at the time of improvement varied from 210 to 1,470 mg. with approximately one half of these doses equal to, or less than, 630 mg. The objective improvement extended over a range of two to seventeen months and continued in about one half of the patients for seven months or longer. These patients were in the sixth to the eighth decades of life and were two to twenty-nine years past the menopause. Pain, the commonest initial symptom, was significantly relieved in 11 of 18 patients with that complaint.

The more noticeable side effects after the administration of androgens were an increase in weight, edema of the lower extremities, deepened voice, hirsutism and acne. Vaginal bleeding, which occurred in 6 of 35 patients receiving estrogen therapy, was in 4 instances due to estrogen withdrawal rather than to continuous medication. There was neither clinical nor laboratory evidence in any case that either the primary or the metastatic mammary cancer had taken an accelerated course because of the androgen therapy. There was an acceleration of growth of mammary cancer in 1 patient, aged 49, after treatment with estrogens.

*Laboratory Results.*—Determinations of the calcium, inorganic phosphorus and alkaline phosphatase of the serum were made before and during treatment of patients with testosterone propionate or ethinyl estradiol. Prior to the institution of endocrine therapy, only minor and occasional abnormalities were observed in the blood chemical studies of the patients without osseous metastases. Of the patients with osseous metastases, 46 per cent had elevations in serum alkaline phosphatase and 23 per cent had elevations in serum calcium.

During the first three months of treatment with testosterone propionate, 63 per cent of the patients with osseous metastases had an increase in serum alkaline phosphatase above pretreatment levels. The alkaline phosphatase in the serum of these patients tended to fall later in the course of therapy. Conspicuous changes in the alkaline phosphatase of the serum of patients without osseous metastases were not observed during treatment with either testosterone propionate or ethinyl estradiol. Of the patients with osseous metastases who had a pretreatment hypercalcemia, 71 per cent had a decrease in serum calcium early in the course of treatment with testosterone propionate. The serum inorganic phosphorus of 56 per cent of all patients treated with either testosterone propionate or ethinyl estradiol decreased significantly during therapy.

Within the limits of a small series of histologic and histochemical observations on regressing cutaneous metastases two changes, which seldom occurred to an unusual degree, were as follows: (1) degenerative changes in the nucleus and the cytoplasm of the cancer cells and (2) fibroblastic proliferation and sclerosis of the connective tissue.

In general, cytologic changes of the exfoliating vaginal mucosa were temporarily in the anticipated direction of basophilia after androgen administration and acidophilia after estrogen administration.

In the stratified squamous epithelium of the cervix the cytoplasmic glycogen content either increased or remained elevated in one half of the cases during androgen or estrogen therapy.

In 15 patients who had received testosterone propionate for an average of seven months the hemoglobin concentration of the peripheral blood increased from an average initial value of 12.6 Gm. to a value of 15.9 Gm. per hundred cubic centimeters.

Postmortem examinations were made of 17 of 55 patients now deceased. Active mammary carcinoma was found in each case.

# POSTABORTAL OLIGURIA

WARD M. O'DONNELL, M.D.
Ann Arbor, Mich.

Renal insufficiency as a complication of pregnancy, and particularly of abortion, has long attracted serious consideration. At necropsy the organs of fatal cases in this group are found with morphologic features in common; and there is a constant relationship between the clinical syndrome and these structural changes. Comparison of this relationship with that resulting from other causes has made possible a more complete explanation of postabortal oliguria.

Bywaters and Beall[1] in 1941 activated interest in the clinical-pathologic picture which followed crush injuries sustained in the London air raids. The triad of crushing injury, subsequent renal failure and histopathologic alterations in the kidneys focused the attention of clinicians and pathologists on this disease entity, which they called the crush syndrome. The onset of symptoms[2] follows in the wake of crushing trauma or other precipitating factors with or without evidence of shock. Nausea, vomiting, malaise and abdominal pain are usually present, but the most ominous sign is renal failure. This may develop insidiously or abruptly and is made evident by oliguria or even anuria, with a rapid rise in nonprotein nitrogenous products in the blood. Hypertension, acidosis and edema may accompany the renal shutdown.

Laboratory studies generally reveal the urine to be acid in reaction, of low specific gravity, dark brown or smoky in appearance and to contain hyaline, leukocytic or granular casts. Frequently a positive reaction to the benzidine test is obtained. Patients in whom these observations are made usually die within twenty days of the onset; the majority succumb within ten days. Pulmonary edema or potassium intoxication are frequent terminal complications.

Bywaters and Beall[1] described the renal lesion as consisting of retrogressive changes in the ascending loop of Henle and the second convoluted tubule with the presence of brown (myohemoglobin) casts in the distal tubular apparatus. Lucké[3] and Mallory[4] contributed many etiologic agents to the rapidly growing list of precipitating causes. Among these are: transfusion reaction of incompatible blood, hemolytic anemia, various poisons, thermal and chemical burns, hemoglobinuric fever, heat stroke, anoxia, high altitude, sulfonamide sensitivity, mushroom poisoning, uteroplacental apoplexy, severe streptococcic infection and infantile diarrhea. More recently others[5] have added nontraumatic ischemia of muscle, pyloric stenosis, infectious hepatitis, operations on the biliary tract and abortion.

Lucké[3] considered lower nephron syndrome an appropriate designation for this clinical-pathologic association, since the presenting anatomic alterations occurred in the lower or more distal aspects of the nephron. The morphologic features, as reviewed by him and by Mallory,[4] consist essentially of degenerative changes and necrosis in the distal convoluted tubules and the deposition of heme (pigmented) casts in the distal and collecting tubules. In addition, there may be seen hyaline casts, herniation of tubules, necrosis and exfoliation of tubular epithelial cells, regeneration of epithelium, precipitation of eosinophilic amorphic material in the glomerular spaces, interstitial edema and exudation of inflammatory cells most prominent at the corticomedullary junction.

Recent literature[6] concerning hepatic dysfunction in the lower nephron syndrome explains central and midzonal necrosis as the result of anoxia.

## REVIEW OF LITERATURE

Until recent years renal failure attendant on pregnancy or abortion often was ascribed to extensive necrosis of the renal cortex. This lesion was the subject of a comprehensive review by Duff and Murray[7] in 1941. They were able to collect 71 cases of symmetric cortical necrosis of the kidneys, 48 of which were associated with pregnancy. It is interesting to note that of the 36 cases in which the month of termination of gestation was listed, only 2 were as early as the fourth month. They found that renal failure usually developed between the fifth and eighth months of pregnancy. Further study showed that there was usually an underlying obstetric complication. In 21 cases it was premature separation of the placenta and in 8 it was preeclamptic toxemia.

In analyzing the clinical course of renal cortical necrosis Duff and Murray[7] found that the onset was usually marked by extreme oliguria or anuria. Other complaints were headache, abdominal pain and, frequently, edema of dependent parts. The urine might be grossly bloody or red blood cells were found microscopically, associated with albumin and hyaline or granular casts. There was retention of nonprotein nitrogenous products varying from 85 to 356 mg. per hundred cubic centimeters. The patients were febrile but maintained mental clarity until a day or two before death.

Duff and Murray[7] described the renal cortical necrosis as of varying degrees of severity, with the most advanced lesions involving the entire cortex. The lesion was believed to be due to ischemia. The vascular changes were thought to be localized in the intralobular arteries and efferent arterioles and to follow a sequence of vasospasm to vasoparalysis frequently associated with thrombosis. As to pathogenesis, the authors postulated a circulating toxic substance, possibly of placental origin, which initiates the derangement in sensitive vascular structures.

A report by Dunn and Montgomery[8] (1941) added 15 more cases of fatal destructive lesions in the renal cortices, 7 of which involved pregnant patients. Six of the 7 had preeclamptic toxemia with either antepartum bleeding or retroplacental hemorrhage. The oliguria lasted from two to seven days.

All these studies had dealt with renal dysfunction in connection with obstetric accidents as related to symmetric necrosis of the kidney. After the crush syndrome had been described, the first association between accidents of pregnancy and lower nephron nephrosis was established by Young and McMichael[9] (1941) who reported 2 cases of renal failure after severe labor. In both patients there developed urinary suppression

and an elevated blood urea level after delivery. One case was fatal, and the histopathologic observations were similar to those of the crush syndrome. Developing an analogy with the crush syndrome, they postulated that a toxin liberated from the injured pelvic soft tissues precipitated renal failure.

Young[10] related a second obstetric problem to the lower nephron syndrome through the common factor of tissue destruction. He found this syndrome to occur in some cases in which there was concealed hemorrhage associated with premature separation of the placenta. Fifty-nine consecutive cases of obstetric hemorrhage with shock (postpartum hemorrhage, placenta previa and premature separation of the placenta) required blood transfusions. Only 5 in the 10 associated with premature placental separation manifested renal impairment. Young concluded that impaired renal function was not due to the shock of hemorrhage. In 79 cases of premature placental separation later in pregnancy renal impairment did not occur in the revealed hemorrhagic variety, but in 25 per cent of the concealed hemorrhagic type there was renal dysfunction. In 3 of the 4 fatal cases in this series, renal findings compatible with the crush syndrome were demonstrated. Thus Young further elaborated the idea that renal failure was determined by a massive uteroplacental lesion of ischemic origin from which a hypothetic nephrotoxic substance was liberated to effect tubular degeneration and azotemia.

Paxson, Golub and Hunter[11] have reported their experience with renal failure and obstetric conditions. In 1 fatal case lower nephron nephrosis was observed in conjunction with premature placental separation and retroplacental hematoma.

The first report pertinent to my observations on postabortal oliguria was by Bratton[12] (1941), who described 8 fatal cases not associated with blood transfusions in women who had septic abortions. The renal lesions were similar to those observed in the crush syndrome. Three of their 8 patients had anuria and 2 of the remaining 5 had blood urea determinations of 423 and 420 mg. per hundred cubic centimeters. In addition, 5 of the 8 patients exhibited some degree of metritis at necropsy. Bratton[12] concluded that the renal changes were probably toxic in origin but not necessarily puerperal, since anuria might have preceded the abortion.

At a later date, Young[10] had opportunity to review the clinical records of Bratton's[12] cases and concluded that in the 3 cases with anuria this difficulty was subsequent to premature separation of the placenta at about the twenty-sixth to twenty-eighth week of pregnancy. In 1 of the remaining cases the patient suffered from retroplacental hemorrhage and eclampsia at the thirtieth week of pregnancy. This further analysis leaves the possibility that anuria in 4 cases was associated with abortion and was not a complication of other obstetric accidents. Unfortunately, Bratton did not give detailed histories for his cases and subsequent investigators have suggested the possibility of drug ingestion by his patients.

Dingle[13] (1943) added 2 more cases in which renal failure occurred following abortion. Both patients were in the sixth month of pregnancy and after the abortion they experienced a drop in blood pressure with a state of shock ensuing. Later, hematuria, oliguria and retention of nonprotein nitrogenous products developed. The first patient, aged 31 and with severe toxemia of pregnancy, yielded 10 ounces (284 cc.) of dark brown urine prior to induced delivery of the fetus. She died on the eighth day. Necropsy disclosed complete necrosis of the renal cortices.

The second patient was thought to have a traumatic premature separation of the placenta and, subsequent to the abortion, hematuria, shock and azotemia (blood urea level 356 mg. per hundred cubic centimeters) developed. After a stormy course of ten days, diuresis was established and the patient recovered.

It appears that the first case was another instance of cortical necrosis complicating pregnancy, but the second case may be an example of lower nephron nephrosis subsequent to retroplacental hemorrhage as described by Young.[10] The obstetric accidents were miscarriages due to toxemia or premature separation.

A further study of renal failure after abortion was made by O'Sullivan and Spitzer[14] (1946). They analyzed 6 cases of acute renal failure after incomplete abortion. The first case was that of a girl aged 19 (period of gestation not given) who had mild pyrexia and an offensive hemorrhagic vaginal discharge. Three days after admission, digital removal of necrotic placental tissue was performed with the patient under intravenous thiopental sodium anesthesia. Four days later, oliguria developed and the blood urea determination rose to 320 mg. per hundred cubic centimeters. Death occurred on the seventeenth hospital day. Bywaters[14] examined the autopsy material and believed the renal findings to be compatible with the crush syndrome. Even though the patient had received chemotherapy and whole blood transfusions, he considered these lesions to be the result of septic abortion.

O'Sullivan and Spitzer[14] presented a second case of inevitable abortion in a secundigravida 45 years of age who was approximately twenty-four weeks pregnant. After the abortion, oliguria developed, and the patient died three days later. Autopsy observations were those of symmetric necrosis of the kidneys. In 2 additional cases of oliguria complicating abortion the patients survived. One patient had oliguria after abortion, but it was ascribed to a transfusion reaction due to incompatible blood.

Humphrey and Jones[5] have recently described 4 cases in which extreme oliguria occurred after incomplete abortion at about sixteen weeks of pregnancy. Symptoms consisted of headache, vomiting and anemia, with hemoglobin varying from 5.5 to 10.6 Gm. per hundred cubic centimeters. Urinary suppression persisted from four to fourteen days, with blood urea determinations ranging from 350 to 550 mg. Diuresis was established and all 4 patients survived. In each instance therapeutic operative evacuation of the uterus was performed under anesthesia.

Finally, it seems advisable to include a case reported by Terplan and Javert[15] (1936) to associate the lower nephron syndrome as a possible complication of quinine poisoning in pregnancy. A woman aged 41, three months pregnant, received a proprietary remedy containing quinine. She experienced vaginal bleeding, anorexia, emesis and extreme prostration of several weeks' duration. The patient died with azotemia on the sixth day after hospital admission. The pathologic descriptions are similar to those in what is now considered to be the lower nephron syndrome. Three grams of quinine were recovered from the liver at autopsy. The authors concluded that the exact mechanism of quinine-induced hemoglobinuria was unknown but thought that pregnant women, particularly those with toxemic tendencies, were susceptible to its hemolytic property.

The impression gained from the literature is that the lower nephron syndrome can be a complication of any period of gestation; however, symmetric cortical necrosis occurs almost exclusively in the latter half of pregnancy. The cortical necrotic lesion in pregnancy is a complication of other obstetric conditions; namely, premature separation of the placenta or toxemia of pregnancy. Although the lower nephron lesion also has been shown to accompany complications of the later months of pregnancy, I believe that it is an important complication of abortion itself. With some reservation, because of brief histories, I might accept 4 of Bratton's[12] cases and possibly 1 of O'Sullivan's[14] as examples of lower nephron injury subsequent to abortion. The 4 clinical cases reported by Humphrey and Jones[5] appear to illustrate recovery from this disease, although anatomic proof is lacking.

## REPORT OF CASES

The following 3 cases add further proof to the presumptive relation between abortion and lower nephron nephrosis.

CASE 1.—A white woman aged 24, estimated to be two months advanced in her third pregnancy, gave a history of abdominal cramps, urinary difficulties and vaginal bleeding with passing of clots, lasting for one week. In addition, during the forty-eight hours prior to hospital admission, there developed malaise and a tan discoloration of the skin. At the time of examination the patient was semicomatose, had a blood pressure of 120 mm. of mercury systolic and 60 mm. diastolic and a temperature of 103 F. Her urine was black and the reaction to the guaiac test for blood was positive. Other laboratory studies revealed hemoglobin of 5.5 Gm. per hundred cubic centimeters, 1,300,000 red blood cells and 28,700 white blood cells per cubic millimeter. The patient was oliguric on admission, and the urea nitrogen concentration of the blood was 131 mg. per hundred cubic centimeters. The carbon dioxide–combining capacity was 32 volumes per cent. During the hospital course of four days the total urinary output was 330 cc. Treatment with penicillin, oxygen, minimal intravenous fluids and whole blood transfusions was of no avail. On the day of death the urea nitrogen level of the blood was 235 mg.

The pertinent microscopic renal findings follow: There was pale eosinophilic material in the glomerular spaces and proximal convoluted tubules. The epithelium of the latter showed simple necrosis to a moderate degree. In the thick limb of Henle and in the distal convoluted and collecting tubules there were reddish brown to tan casts. The distal convoluted tubules presented extensive necrosis and exfoliation of epithelial elements. In addition there was early regeneration of epithelial lining cells. Slight interstitial edema and minimal scattered peritubal lymphocytic inflammatory infiltration also were found.

Pathologic diagnoses included: lower nephron syndrome; recent abortion with retained placental tissue showing acute necrotizing deciduitis and endometritis; acute parenchymatous degeneration of liver with extensive midzonal necrosis; moderate degenerative lipidosis of the liver, and acute pulmonary edema.

CASE 2.—A white woman aged 35 in her sixth pregnancy was hospitalized Oct. 26, 1939. Her last menstrual period began Aug. 28, 1939. The patient stated that she missed the menstrual period in September and, thinking herself to be pregnant, inserted slippery elm into her cervix, leaving it in place for two days. There resulted a white vaginal discharge, which became bloody on October 25 and was associated with nausea, vomiting, generalized malaise, pain in the lower part of the abdomen and, finally, chills and fever. Physical examination revealed that the patient was passing clots of blood and the uterus was slightly enlarged. A small fragment of tissue extruding from the external os was identified as placenta and removed. Jaundice was present at this time. The temperature was 102 F., and the blood pressure was 95 mm. of mercury systolic and 70 mm. of mercury diastolic. The patient was oliguric on admission, and the urine gave a 4 plus reaction to the benzidine test. The white blood cell count was 27,000 per cubic millimeter, and the hemoglobin value was 71 per cent. The patient's total output of urine during hospitalization was 340 cc. Therapy consisted of transfusions of whole blood, sulfanilamide therapy and general supportive measures. The patient died on the third hospital day, seventeen days after a self-induced abortion.

The more significant observations at necropsy were in the kidneys. Many collecting tubules contained pigmented casts in which spherical outlines persisted. In other tubules the casts were more uniform and reddish brown. Pigmented casts were seen also in the distal convoluted tubules, where the lining epithelium showed widespread simple necrosis. There was an eosinophilic precipitate in the glomerular spaces. Mild interstitial edema and scattered lymphocytic inflammatory infiltrations were limited almost exclusively to the medulla. There were signs of old chronic purulent pyelitis and hydronephrosis.

Pathologic diagnoses included: lower nephron syndrome; recent abortion with necrotizing deciduitis; septicemia (Streptococcus viridans recovered from the heart's blood at necropsy); acute parenchymatous degeneration of the liver with moderate degenerative lipidosis, and icterus.

CASE 3.—A woman aged 42 manifested a bizarre clinical picture following an early abortion. The illness was of about twelve days' duration. There was well defined oliguria, with only 300 cc. of urine being passed during this period. Jaundice was present. The attending physician thought the clinical picture compatible with an acute nephritis developing subsequent to an abortion. Etiologic factors such as quinine, sulfonamide drugs, transfusion reaction or other medicinal agents were ruled out by the history. The patient was mentally alert until about one hour before death.

In the kidneys there was an eosinophilic, finely granular precipitate in the glomerular spaces and in the lumens of the proximal convoluted tubules. Pigmented (heme) casts were found in the thick loops of Henle, in the distal convoluted tubules and most abundantly in collecting tubules. In the thick limbs of Henle's loops and in the distal convoluted tubules simple necrosis and regeneration of the epithelium were present. There was moderate interstitial edema. In the outer zone of the medulla there was a peritubular cellular infiltration of lymphocytes and a few eosinophilic leukocytes.

Pathologic diagnoses included: Recent abortion with necrotizing purulent deciduitis; lower nephron syndrome; acute parenchymatous degeneration and passive congestion of the liver, and icterus.

## COMMENT

*Points of Similarity.*—In each of the preceding cases there was an early termination of pregnancy. In none did gestation extend beyond the sixteenth week. In none was there a history of preexisting renal disease. Oliguria developed in each instance prior to the use of therapeutic measures which are admitted etiologic agents in their own right (sulfonamide drugs and whole blood transfusions). In case 1 the possibility that quinine had been taken was explored because of certain social and economic implications. Mindful of this possibility from Terplan's[15] case, the use of quinine was excluded on the basis of clinical observations and by interrogation.

The symptoms described are in accord with the usual manifestations of the crush syndrome; namely, abrupt onset, headache, malaise and vomiting. In the instances in which such information was available, there was elevation of the nonprotein nitrogen level, and in each case severe oliguria was a feature. The first patient died six days, the second four days and the third twelve days after onset of symptoms. Incomplete infected abortion was a factor in common, and an exceedingly important similarity was that septicemia developed in each patient.

Jaundice was present in 2 of the 3 patients, and the other had hepatic zonal necrosis. This fact will be considered in the pathogenesis, as will also the anemia, which appeared to be severer than could be accounted for on the basis of physiologic anemia of pregnancy or vaginal bleeding.

The morphologic aspects of the 3 cases are strikingly similar, the essential pathologic diagnosis being almost identical. The renal observations are those previously described for the crush or lower nephron syndrome with individual variations in accordance with the duration of symptoms. In the case with the longest survival there was more tubular epithelial regeneration and a greater degree of inflammatory infiltration.

The uterine observations were equally interesting. In each case there were large masses of retained decidua and of chorionic epithelium. Part of the placental tissue was necrotic and was undergoing lysis or exhibited extensive cellular inflammatory infiltrations. However, other portions of the placenta were living and bathed in maternal blood. This association of necrotic and living placenta — the latter retaining some degree of maternal circulation — may be of importance in considering the pathogenesis of this disease.

The hepatic lesions were striking and significant in view of the jaundice. In each case there was diffuse simple necrosis of hepatic cells with a decided regeneration of liver cells, hyperchromatic nuclei and multinucleated cord cells. Degenerative lipidosis was observed in the first 2 cases. In addition, the liver in case 1 showed pronounced midzonal necrosis. From general pathologic experience it appears that icterus was due to hepatocellular dysfunction produced by a toxic substance. Our observations were somewhat different from those of Bywaters,[6] who found mitotic activity and central and midzonal necrosis with small intracellular hydropic vacuoles, occurring as soon as the sixth day after trauma. As previously stated, Bywaters explained these lesions on the basis of anoxia.

*Pathogenesis.*—The pathogenesis of the crush syndrome is not satisfactorily explained by any single hypothesis and is probably a process dependent on related forms of renal injury, received under varying conditions. Corcoran and Page,[16] in developing their concept of the genesis of this disease, considered that the mechanism of development can be divided into two phases — the first, in which the principal lesion is obstruction of the renal tubules by hemoglobin or myohemoglobin casts, and the second, in which necrosis of the renal tubular epithelium is produced. Moreover, these authors expressed their belief that hemoglobinuria and myoglobinuria are injurious only when the conditions of aciduria and oliguria are fulfilled and that tissue damage is dependent on deposition of pigment casts within the tubules. It was further postulated that myoglobin and hemoglobin may be transformed and precipitated as metaforms with subsequent release of cytotoxic hematin.

A hypothetic nephrotoxic substance has been incriminated in the crush syndrome, but it is difficult to account for such selective action (distal convoluted tubules) by a chemical substance. It seems far more logical to consider that the chemical substance is a humoral vasoconstrictor and that its mode of action is renal ischemia. The pigment casts may be thought of as products secondary to release of hemoglobin and to breaking down of erythrocytes, which pass through the altered glomerular barrier.

Regardless of postulates, renal ischemia appears to be the decisive underlying factor of the crush syndrome. Recent work by Trueta and his associates[17] has established this last concept on a firm basis through a series of experiments which yielded important anatomic and physiologic considerations. This group studied the renal circulation by angiographic and other injection methods in a series of experiments designed to simulate the crush syndrome. After prolonged application and subsequent release of a tourniquet applied to the hind leg of a rabbit, it was observed that the surface of the kidney became pale while simultaneously the stream of blood in the renal vein was intensely red. More detailed study demonstrated that the ischemia, or reduced blood flow, was more prominent in the outer cortex. These observations were interpreted as a diversion of the renal circulation from the cortex to the medulla by a short-circuiting route; it was believed that the radiopaque material followed this path as an alternative renal circulation. Additional proof of this shunt was obtained from the anatomic differences between the cortical and the medullary vascular supply as derived from the renal efferent arterioles. Similar results were obtained by stimulation of the central end of the divided sciatic nerve, and mediation of reduced cortical flow through a neurovascular mechanism could be postulated.

The experimental injection of staphylococcus toxins in animals produced equivalent results; that is, vasospasm of renal cortical arteries, diversion of the renal circulation through the medulla and, after twenty-four hours, necrosis of the cortex.

This work indicated that the oliguria or anuria due to crushing injuries results from diversion of the renal cortical circulation to a degree which lowers the intraglomerular filtration pressure. The cause could be a neurovascular mechanism dependent on humoral vasoconstrictors released from ischemic tissue, or these hypothetic chemicals might act directly on the vascular structures.

Eggleton,[18] in experimental production of the crush syndrome in the cat by prolonged ischemia, noted that rapid restoration of the circulation in the ischemic limb would depress renal function as evaluated by urea clearance determinations. If the reestablishment of the circulation was gradual, there was no reduction in urea clearance, provided that hepatic function was normal. In those experiments in which the function of the liver was eliminated (clamping of the hepatic artery just prior to gradual release of the limb), there was a depression of urea clearance comparable to that occurring after sudden release of the tourniquet. This suggested that a toxic product is formed during ischemia, which, if slowly liberated into the blood stream, can be detoxified by the intact liver, thus sparing the renal circulation. Eggleton[18] also produced an extract from ischemic muscle or undamaged normal muscle (four to ten hours after death of the animal) which depressed urea clearance when injected into animals. In explanation she quoted the work of Bergmann and Fruton[19] (1941), "who suggested the toxic material might well be an early breakdown product of protein, formed only during strict long continued anaerobiasis and never during normal aerobic protein catabolism in the cell."

[18] Eggleton, M. G.: Crush Kidney Syndrome in the Cat, Lancet **2**: 208-210 (Aug. 12) 1944.

In our cases it is probable that the theoretic substances had origin in the retained placental tissue. These products may be derived from the areas of dead and dying placental tissue in various stages of lysis and may be absorbed into the circulation which persists in the living portions. Young[20] has long considered this to be the explanation of renal failure associated with retroplacental hemorrhage in premature separation of the placenta and in certain cases with eclamptic phenomena.

Since it has been demonstrated that severe septicemia can produce diversion of renal flow, as shown by Trueta's[17] staphylococcic toxin experiment, this also must be considered as a factor in the pathogenesis of oliguria in septic abortion. In this connection necrotic and partially necrotic placental tissue may serve merely as a culture medium for bacterial growth and toxin production. It is also possible that both factors—a hypothetic vasoconstrictive humoral substance from ischemic placenta and toxins from invading bacteria—might, by a synergistic effect, act on a susceptible neurovascular mechanism to produce reduced cortical flow, a result not obtainable by either acting separately. The role of bacterial toxins may be that of producing hepatic damage sufficient to produce hepatocellular dysfunction and inability to detoxify circulating placental products. These substances then would be free to act unfavorably on the kidneys. If this is the case, it constitutes a clinical application of Eggleton's[18] studies.

It is difficult to explain the anemia in case 1, which appeared to be severer than the relative anemia of pregnancy and more than that which a moderate vaginal hemorrhage would produce. This patient may have had secondary anemia prior to the abortion. However, acute hemolytic anemia is frequently observed in septicemia. In the material studied by Humphrey and Jones[5] anemia was a constant feature. However, none of their cases was complicated by generalized septicemia. There was no evidence of hemolytic activity or deposition of hemosiderin in reticuloendothelial cells in either of our first 2 cases. Nevertheless, it does not seem justifiable to exclude completely a hemolytic component as a contributing factor in the pathogenesis of fatal oliguria. This position is supported by the demonstration of mild hemolytic activity in the third case. By the use of special stains a positive iron reaction, indicative of hemoglobinemia, was produced in both liver and spleen. As previously stated, the septic state may have precipitated this condition or the hemolytic phenomenon[10] might have been a side effect of the postulated vasoconstrictor substance derived from the placenta. In sufficient concentration hemoglobinemia could be the initiating factor in vasoconstrictive renal ischemia; in lesser amounts its effect would be contributory.

Consideration of individual susceptibility to circulating chemical substances is essential, because oliguria following abortion is rare although abortion itself is a common occurrence. A state of generalized septicemia appears to be a prerequisite for the production of fatal oliguria after abortion.

What, then, is the relation between the lower nephron syndrome and symmetric cortical necrosis of the kidneys? Over half the cases of cortical necrosis, as reported in the literature, are related to obstetric abnormalities, and most reviews incriminate a placental factor in the pathogenesis of this lesion. Cortical necrosis may be considered a severer stage of lower nephron nephrosis, differing in the degree of cortical ischemia. With this lesion not only is intraglomerular pressure reduced below the level of optimum function but the blood supply is actually insufficient to meet the needs of cortical nutrition. A quantitative factor, either the amount of circulating toxins or the intensity of individual neurovascular response, may decide the morphologic pattern in these two conditions. The complete cessation of cortical flow would prevent hemal elements from passing through the glomeruli in quantity; therefore, pigmented casts would not be deposited in the tubules. Cortical necrosis is observed later in pregnancy, when the amount of toxin, which is absorbed, may be greater.

The histopathologic changes in the lower nephron syndrome, with emphasis on simple retrogressive changes such as simple necrosis in the distal convoluted tubules and the thick limb of Henle, can be accounted for by the deficient cortical vascular supply in partial renal ischemia. The loop of Henle and the collecting tubules, as shown by Trueta,[17] receive nutrient blood directly from efferent arterioles. In contrast, the proximal and distal convoluted tubules adjacent to the glomeruli receive blood which has already passed through the cortical intertubular capillary bed and thus contains less oxygen.

From a therapeutic point of view it appears that early evacuation of the uterus is indicated in nonseptic abortion associated with oliguria. Similarly, in septic abortion it should be to the patient's advantage to have retained placental tissue removed as soon as operability is established. This is considered of prime importance to promote reversal of oliguria or anuria, provided that they are already present, and to prevent the development of the degree of renal impairment which they signify.

## SUMMARY AND CONCLUSIONS

In 3 patients who died subsequent to septic abortion the clinical and histopathologic features of lower nephron nephrosis were observed. Fatal lower nephron nephrosis appears to be a comparatively rare complication of abortion, considering the number of persons exposed to this risk. Its development may depend on a hypothetic precipitating factor (nephrotoxic substance) derived from dead or dying placental tissue. This product in association with the septic state, perhaps synergistically, may initiate renal ischemia in susceptible persons.

Evacuation of the uterus, when the time of intervention is in accordance with surgical operability, may render the prognosis more favorable in septic abortion complicated by renal impairment.

Lower nephron nephrosis following abortion may be a clinical factor more commonly than the literature indicates at present.

# BLACK HAIRY TONGUE ASSOCIATED WITH PENICILLIN THERAPY

SAMUEL A. WOLFSON, M.D.
Los Angeles

Local reactions from the use of oral penicillin (glossitis, stomatitis and vesicular cheilitis) have frequently been described. However, another type of reaction has been reported in the foreign literaure [1] but not in the American journals. The condition itself, black hairy tongue, has been known for many years, but its association with penicillin therapy is of recent note. I have observed this reaction to penicillin and believe that it is of sufficient interest to be documented.

## REPORT OF CASES

CASE 1.—In January 1948 a white woman aged 37 had been using penicillin lozenges for a sore throat. Discoloration of the tongue was observed a few days later. She was examined on the eighth day, at which time the tongue presented a velvety appearance and was brownish black on its medial and posterior portions. The filiform papillae were hypertrophied and bent like the nap of wet, heavy velvet when stroked with a tongue blade. The discoloration gradually cleared, and there has been no recurrence. The significance of the occurrence was not realized at the time.

CASE 2.—A white man aged 59, who had been admitted repeatedly to the Wadsworth General Hospital for treatment of bronchitis, was admitted again on July 12, 1948 for treatment of the same condition. Penicillin had not been used previously, but aerosol penicillin was administered on this admission. A black hairy condition of the tongue developed. No note was made of the date on which the discoloration first appeared. Penicillin therapy was discontinued. The tongue was treated with 50 per cent trichloracetic acid, and the abnormality cleared completely (fig. 1). The patient had subsequent admissions, at which times the tongue was normal.

CASE 3.—A white man aged 59 was admitted to the Wadsworth General Hospital on Aug. 12, 1948 for treatment of bronchitis and pneumonitis. The pneumonia cleared following the intramuscular injection of 50,000 units of penicillin every three hours for eight days (Aug. 12 to 20, 1948). However, the bronchitis persisted and aerosol penicillin, 50,000 units twice a day, was administered from September 15 to 30. No note was made of the time when the discoloration first appeared, but typical black tongue was seen on September 23, after eight days of therapy. The color was a greenish black and involved the back, medial furrow and pads but not the tip or sides of the tongue (fig. 2). Filaments teased from the tongue resembled, morphologically, the filiform papillae of black hairy tongue. In addition, Candida was cultured from the tongue scrapings. The tongue returned to normal when penicillin therapy was discontinued. The patient was last examined on April 30, 1949, at which time the tongue was still normal.

CASE 4.—A white woman aged 34 had used penicillin troches for five days, omitted them for four days and resumed taking them for two more days. The tongue showed discoloration after the first five days and became progressively darker. She was seen on April 19, 1949, five days after all therapy had been discontinued. The filiform papillae of the posterior, medial and pad portions of the tongue were hypertrophied and had a heavy dark brown color and plushlike appearance. Warm, saline mouth rinses with gentle scraping of the tongue were recommended. The patient was seen periodically, and the tongue was normal again by May 14, 1949.

## COMMENT

*Etiologic Basis.*—Black hairy tongue is an uncommon disease of unknown causation, although it is thought in some instances to be due to a congenital abnormality which develops in later life. Prinz and Greenbaum [2] have expressed their belief that "it is due to some constitutional state in the form of a trophoneurotic disturbance which electively predisposes the surface of the tongue to irritation by specific substances." Histologically, the filiform papillae are hypertrophic and hyperkeratotic and are the origin of hairlike filaments that may grow as long as ½ inch (1.27 cm.). The papillae become densely matted, and deposition of pigment takes place. The papillae may become covered by accumulations of bacteria and molds, which are part of the normal flora of the mouth. The pigment is considered to be derived from food, wines, tobacco, drugs such as iron and mercury and mouth washes that contain oxidizing or reducing chemicals.[2] According to Lederer,[3] the condition is frequently associated with an unhygienic mouth. Primarily, however, the pigment originates in a local chemical reaction between the decomposition products of food debris and the iron present in the minute quantity of blood that can be found almost all of the time near the free margins of the gums and between the teeth. It should be pointed out that the patients of this report were not heavy users of tobacco, had not been using strong mouth preparations or medicaments and were considered to have good oral hygiene.

Black tongue has also been caused by the filamentous myceliums of actinomycosis which have been cultured from the tongue.[4]

Cross [1b] estimates that discoloration of the tongue constitutes at least 30 per cent of all oral reactions in patients taking oral penicillin. The discoloration appears as early as two days, as late as nine days and on an average of four days following the use of penicillin. It is a pigmentation of the filiform papillae and involves principally the back of the tongue, the central furrow and portions of the pads, leaving the sides and tip unaffected (fig. 2). The color varies from yellowish brown to black.

*Mode of Action of Penicillin.*—The manner in which the penicillin acts is uncertain. Bedford's [1c] impression was that the discoloration was due to either a fungus or a chromogenic bacterial growth which followed the inhibitory action of penicillin on the usual flora of the mouth, which in turn act as inhibitors of other organisms. However, Cross [1b] failed to recover fungi or chromogenic bacteria.

Ellinger and Shattock [1d] studied the urinary nicotinamide output and found it greatly diminished under oral penicillin therapy. They thought that penicillin inhibited the growth of intestinal organisms involved in the synthesis of nicotinamide and that the oral reaction was related to a deficiency of this vitamin. However, they also considered local contact to be an important factor. In order to test the theory of nicotinamide deficiency, Cross [1b] treated a number of patients with oral penicillin

plus nicotinamide and observed that discoloration of the tongue developed in 20 per cent of the group.

Irritation from the lozenge base was investigated, but the use of lozenges consisting only of base did not produce a reaction. Certainly no such possibility existed in the 2 patients herein reported, who were treated with aerosol penicillin.

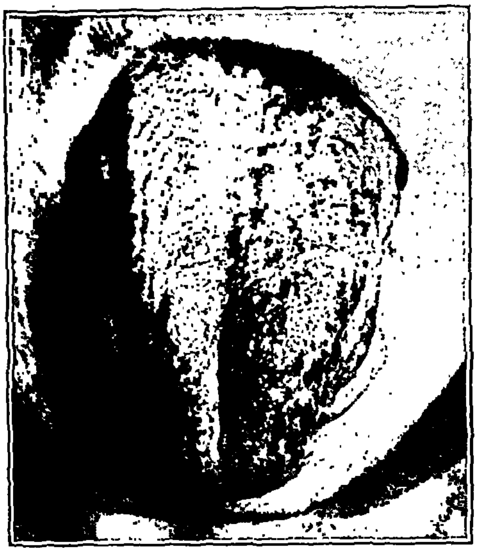

Fig. 1 (case 2).—Appearance of tongue after the application of 50 per cent trichloracetic acid. Residuals of the black tongue are still evident. The discoloration subsequently cleared completely.

Lastly, individual sensitivity to one or more forms of penicillin or their impurities has received attention. In this study I did not subject any patient to another course of penicillin in an attempt to reproduce the condition. One of Ackers'[1a] patients willingly took penicillin after the tongue had cleared. Black tongue developed again and cleared once more in about three weeks. In view of the experience with other local irritants, such as sodium perborate and tobacco, the most likely cause would appear to be the irritating action of the antibiotic. However, that would not explain a most interesting feature described by Lahiri.[1c] His patient received 50,000 units of penicillin intramuscularly every three hours for a total dosage of 500,000 units. Six hours after the last injection the patient noticed that his tongue was black and covered with black fur. When observed again twelve hours later the fur was gone and the tongue looked perfectly normal. If penicillin was the offending agent then it could only have acted directly through the blood stream, because, as demonstrated by Rammelkamp and Keefer,[5] penicillin does not appear in the saliva following intravenous administration. That does not necessarily imply that penicillin cannot act as an irritant in a limited predisposed area via the blood stream. The fact that the tongue cleared in the course of only twelve hours is also exceedingly surprising in view of other observations. In case 3 of this report the patient had had intramuscular injections of penicillin every three hours for eight days without the development of black tongue; and yet when aerosol penicillin therapy was started twenty-five days later, black tongue was noted on the eighth day of therapy. If penicillin can act via the blood stream, why did it not do so on a tongue that reacted so readily to oral administration of the agent? Perhaps future reports will confirm Lahiri's observation.

Histologic examinations have not been made of the tongues with discoloration due to penicillin. Clinically the hypertrophy of the filiform papillae is moderate; perhaps the absence of a severe and advanced form is what accounts for the ease of its resolution and its nonrecurrence. It may be that the more stubborn and chronic form would develop under prolonged and repeated use of penicillin.

*Therapy.*—There is no specific therapy for removal of the discoloration due to penicillin from the tongue. Cross[1b] noted *in many instances* that the oral cavity either became sterile or contained coliform organisms, and that the change usually took place in forty-eight hours. He reasoned and cautioned that oral treatment with penicillin should be limited to that period if black tongue is to be avoided. Once the discoloration has developed it can be reversed by interrupting the penicillin therapy. The tongue will return to its normal state in about one month. Adjunctive treatment with mouth washes and rinses is of doubtful value. In case 2 treatment with 50 per cent trichloracetic acid was initiated, but in the light of later experiences this should not have been necessary. Naturally, any compound containing strong oxidizing or reducing agents which may act as irritants should be avoided. In the remainder of the patients the condition resolved fairly rapidly when penicillin therapy was discontinued. This and the absence of recurrences are strong evidence that penicillin plays a role in the production of the black tongue, albeit the manner in which it acts is still uncertain.

*Prevalence of Condition.*—It is interesting that Cross[1b] noted discoloration of the tongue in 20 per cent of a group being observed for that specific effect. I am sure that that figure will prove not to be too high if careful observations are made in all persons using penicillin, particularly oral preparations. About two years ago a physician called attention to a discoloration of his tongue during the administration of aerosol penicillin. The discoloration was considered just a coating and was attributed to the illness for which he was being treated. The tongue cleared and has remained normal. In retrospect, the discoloration of his tongue was due to penicillin. I feel certain that many discolored

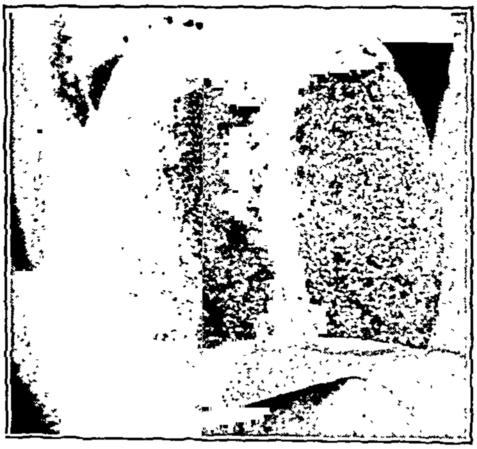

Fig. 2 (case 3).—Involvement of the posterior, medial and pad portions of the tongue with the sides and tip remaining clear. The posterior portion was most heavily involved but could not be adequately photographed. The discoloration resolved completely.

these tests, the beauty clinic operators were instructed to insure thorough wetting of the scalp with the waving lotion, in order to circumvent any criticism that expert care could in any way modify the results. Furthermore, the careful records of the beauty clinic on many thousands of cases lend further support to the results on this smaller group.

Clinical studies to ascertain the presence of any systemic manifestations of toxicity were performed on this group of heavily exposed persons. Toxicologic evidence on animals[1] shows, and one clinical report[2] alleges hepatotoxic effects from the cold waving solution, while ingestion of the neutralizer may result in nephrotoxic manifestations.[3]

Of the 441 factory employees subjected to patch testing, 226 permitted the performance of complete laboratory studies. This group included 72 persons in daily intimate contact with the waving lotions and chemicals. The laboratory studies comprised a complete blood examination including determination of hemoglobin concentration, erythrocyte, leukocyte and leukocyte differential counts, an examination of the blood smear for abnormal cells and an estimation of the number of platelets. The urine was examined for albumin and reducing substances, and the sediment was examined microscopically. Tests for hepatic function, consisting of the cephalin cholesterol flocculation, prothrombin time and icteric index, were made.

Various deviations from the normal for one or more of these tests were obtained in 51 subjects. Of the 51, 43 permitted complete physical examination and the recording of a detailed medical history. Those who manifested any deviation from the normal in the liver function tests were subjected to the following additional tests: the thymol turbidity, sulfobromophthalein sodium excretion, the twenty-four hour excretion of urobilinogen and of coproporphyrin, the prothrombin response to vitamin K and a blood Wassermann determination.

The results of the blood examination were well within normal limits, the distribution, as exemplified in the accompanying chart, being that seen in general clinical practice in the St. Paul area.

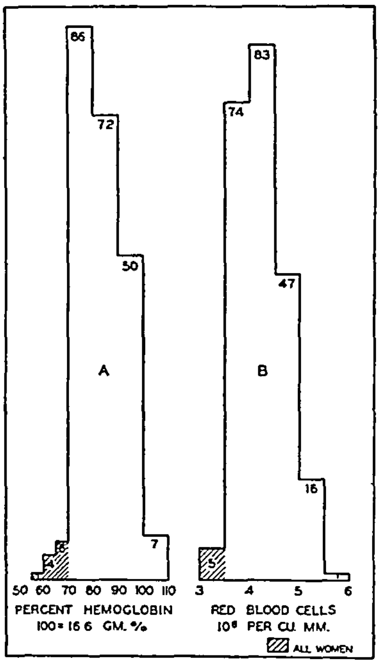
Urinalysis revealed the presence of reducing substance (glycosuria) in 8 of the 226 persons so examined, 2 of whom were positive on repeat tests and were found to have diabetes mellitus unrelated to contact with the chemicals. Less than 1 plus reaction for albumin was found in the voided urine of 15 women and 4 men. On retesting 13 of these subjects, the urine of 12 gave negative reactions to albumin and of 1 gave a faint trace. In 1 man the urine gave a 2 plus reaction for albumin, but he gave a history of albuminuria existing long before his present employment, which required daily contact with the waving lotion. The tests for liver function were performed on all these subjects with negative results. Microscopic examination of the urine did not reveal findings of significance to this investigation.

The icteric index was within the normal limits of 4 to 6 units. The prothrombin time was elevated in 10 of the subjects. Nine of these submitted to a most complete medical examination, including vitamin K response tests, sulfobromophthalein sodium retention tests and urobilinogen and coproporphyrin excretion studies. Results of all tests were within normal limits; hence, the origin of the elevation in prothrombin time was not revealed, and it was considered as a spontaneous deviation.

The cephalin flocculation tests never exceeded a 1 plus reaction in 24 hours or a 2 plus reaction in 48 hours and were considered as being within normal limits. The results are summarized in table 4.

Thymol turbidity examination of 13 subjects who had a 2 plus reaction with the cephalin flocculation test showed 2 subjects with a value of 5 units and 1 with 6.8 units. These figures are considered to be within normal limits.[4]

Physical examination was given to 43 of the 51 subjects who showed any deviation whatever from the normal on any of the laboratory tests. In interpreting the paucity of positive results, it should be noted that these men and women were substantially healthy persons employed at their various tasks. A few manifested some of the usual variety of abnormalities which would be encountered in any series of routine physical examinations of asymptomatic subjects. In no instance did either the history or the physical examination yield any evidence of any acute or chronic condition which might be expected in the presence of disease of the liver, the kidneys or the hematopoietic system.



Results of examination of blood in persons manifesting deviations from normal in liver function tests.

CONCLUSIONS

1. On the basis of these studies, cold wave preparations used in this investigation exhibited a low level of cutaneous irritation.

2. These preparations show a low sensitizing potential. Cutaneous reactions from contact with or exposure to these materials are of a negligible incidence.

3. In the literature attention has been directed to toxic manifestations, primarily, of a hepatotoxic nature, resulting from the use of cold wave preparations. Careful and intensive studies of a clinical and laboratory nature do not support the contention that toxic manifestations result from the use of cold wave preparations. Evidence of systemic toxicity from frequent exposu to the cold waving solutions tested was not found.

4. Cold wave lotions of the composition set forth in this paper are safe for general use.

tongues are seen; however, the manifestation is not recognized as due to penicillin but attributed to the associated illness. On the tongues of lighter coloration the condition could easily escape detection. Undoubtedly, the manifestation will be more frequently recognized as its association with penicillin becomes more widely known.

SUMMARY AND CONCLUSIONS

Four cases of black hairy tongue associated with penicillin therapy are reported. The opinions of previous observers regarding the possible modes of action of the penicillin are discussed; however, the precise mechanism of its action is yet to be demonstrated.

St. Paul
With the assistance of Jerome Kaufman, M.D.; Herbert Fishbein, M.D., and Willard F. Greenwald, B.S., Ch.E., New York

This report concerns the effects of certain cold wave lotions on the health of 1,200 persons who volunteered for tests of these products. Millions of people are exposed to such chemicals. The 1,200 persons included normal persons and some with various skin diseases; persons without any known contact with cold waving lotions, as well as a great number subject to prolonged previous contact. The main active ingredient in cold waving lotions is ammonium thioglycolate. The material employed in these tests was Toni Home Wave. Because the chemical reactivity of cold waving lotions is affected by the concentration of ammonia and ammonium thioglycolate, by the alkalinity ($p_H$) and by the type and amount of wetting agent used, the data here reported cannot be applied to lotions containing ammonium thioglycolate with different concentrations of the adjuvants.

Previous reports on the medical aspects of cold waving lotions are meager and replete with contradictions and equivocations. A summary of the dermatologic reports is shown in table 1.

EXPERIMENTAL DATA

Patch tests were employed in the evaluation of cutaneous irritation and sensitization. The test materials included the commercial cold waving lotion, fresh and shelf-aged for a year; a 2 per cent solution of potassium bromate (neutralizer); mixtures of lotion and neutralizer in varying proportions, and solutions of ammonium thioglycolate at $p_H$ 9.2 and concentrations of 0.5, 1.0 and 1.5 normal for the determination of primary irritation. By the use of adequate numbers of paired patch tests on subjects with (*a*) no known previous contact with cold waving solutions, and (*b*) varying contact with the solutions; by the retesting of each subject within two to four weeks, and by interpreting the results in conjunction with a large body of data obtained under conditions of actual use of the waving solution, we conclude that these solutions have a low degree of irritancy, even when used in concentrations triple that used in practice, and a negligible power of sensitization.

Paired patch tests with the various cold waving solutions were performed at Bellevue Hospital on 286 patients (143 women, 143 men) with varous cutaneous diseases such as fungous infections (63), eczematous dermatitis (61) and others (162). One patient exhibited a weakly positive unilateral reaction but was unavailable for retest. Retesting 109 of the remainder twenty to forty days later yielded two weak reactions, one unilateral and the other bilateral. The latter was negative on a second retest. Tests including a lock of hair under the patch with the wave lotion did not result in reactions. Variation in the size of the patch from the usual ¼ inch to ½ inch and 1 inch (0.64 cm. to 1.27 and 2.54 cm.) did not affect the incidence of reactions.

Subjects with varying known contact with the cold waving solutions were available in St. Paul. The incidence of contact of these subjects with the various waving materials is shown in table 2. Included in the total of 931 subjects were 441 factory workers, some of whom were in daily and intimate contact with the chemicals. A careful study of the turnover rate of employment of this group showed it to be commensurate with the general rate of the locality. Furthermore, close questioning of employees who had resigned did not reveal any obvious connection between the reasons given for resigning and the degree of contact with the cold-waving chemicals during employment.

Paired patch tests were carried out on 863 of these subjects. The incidence of reaction is given in detail in table 3. Of the 16 initially positive reactions (of which 2 were 2 plus, all others being less), 2 were positive on retest and 1 was not retested. One of the reactors was a male factory worker who was exposed constantly during work to the cold wave chemicals. This constituted an incidence of 0.26 per cent in the 390 members of the factory group who had varying contact with the lotions. The other reactor to patch tests had had five cold waves without any reaction. Statistically this gave an incidence of 0.3 per cent among the 345 women who had had contact only during the administration of a cold wave permanent. None reacted to the neutralizer solution.

Thorough examination of the scalp of 174 subjects undergoing actual waves with the commercial waving materials was made (G. W.). Each of these women had had previously from one to twenty cold waves. Preliminary examination revealed excoriations and seborrheic dermatitis in 29 of these women.

Adverse effects were not seen either immediately or one week following the cold wave. Areas of slight erythema ascribable to hair pulls or overheating by the dryer disappeared within a day or two. During

This article has been abbreviated in THE JOURNAL. The complete article and tabular data may be found in the authors' reprints.

This investigation was aided by a grant from the Toni Company, Chicago. A sample was submitted to Foster D. Snell Laboratories for chemical analysis. They reported as follows: The waving lotion, $p_H$ 9.21, contained ammonia by titration 0.86 per cent and thioglycolates (as thioglycolic acid) 4.61 per cent. The neutralizer gave positive tests for potassium and bromate (*label states, "... contains potassium bromate"*).

these tests, the beauty clinic operators were instructed to insure thorough wetting of the scalp with the waving lotion, in order to circumvent any criticism that expert care could in any way modify the results. Furthermore, the careful records of the beauty clinic on many thousands of cases lend further support to the results on this smaller group.

Clinical studies to ascertain the presence of any systemic manifestations of toxicity were performed on this group of heavily exposed persons. Toxicologic evidence on animals[1] shows, and one clinical report[2] alleges hepatotoxic effects from the cold waving solution, while ingestion of the neutralizer may result in nephrotoxic manifestations.[3]

Of the 441 factory employees subjected to patch testing, 226 permitted the performance of complete laboratory studies. This group included 72 persons in daily intimate contact with the waving lotions and chemicals. The laboratory studies comprised a complete blood examination including determination of hemoglobin concentration, erythrocyte, leukocyte and leukocyte differential counts, an examination of the blood smear for abnormal cells and an estimation of the number of platelets. The urine was examined for albumin and reducing substances, and the sediment was examined microscopically. Tests for hepatic function, consisting of the cephalin cholesterol flocculation, prothrombin time and icteric index, were made.

Various deviations from the normal for one or more of these tests were obtained in 51 subjects. Of the 51, 43 permitted complete physical examination and the recording of a detailed medical history. Those who manifested any deviation from the normal in the liver function tests were subjected to the following additional tests: the thymol turbidity, sulfobromophthalein sodium excretion, the twenty-four hour excretion of urobilinogen and of coproporphyrin, the prothrombin response to vitamin K and a blood Wassermann determination.

The results of the blood examination were well within normal limits, the distribution, as exemplified in the accompanying chart, being that seen in general clinical practice in the St. Paul area.

# CONGENITAL DEFECTS FOLLOWING MATERNAL RUBELLA

STUART ABEL, M.D.
and
THEODORE R. VAN DELLEN, M.D.
Chicago

Gregg[1] in 1941 was the first to suggest a relationship between maternal rubella and congenital defects in the child. He studied 78 cases of congenital cataract associated with cardiac or other lesions and in 68 obtained a maternal history of rubella during pregnancy. Since this initial work in Australia, many reports have appeared on this subject. Various congenital defects, particularly cataracts, cardiac malformations and deafness have been reported. Mental retardation, hypospadias, talipes equinovarus, underdevelopment, difficult feeding problems and dental abnormalities also have been mentioned.

Further studies disclosed that rubella in the mother during the first trimester of pregnancy is most likely to affect the child. Swan,[2] Evans[3] and their Australian colleagues followed Gregg's lead and concluded that congenital defects resulted in 100 per cent of babies born to mothers having rubella in the first two months of pregnancy and 50 per cent of children born to women who had the disease in the third month. Subsequent studies by others have revealed that the chance of an infant's developing such a defect is perhaps not as high as early reports would indicate, although Conte's[4] recent review of the available data shows a startling correlation with results in earlier studies. This review includes 134 cases in which maternal rubella was followed by congenital abnormalities. In all but 3 instances rubella appeared in the first trimester of pregnancy. Congenital cataracts, congenital heart disease and mental retardation were the chief defects. Twenty cases of maternal rubella without congenital malformation in the infant are included in Conte's survey; in 4 rubella struck in the third month and in the remaining 16 cases, after the first trimester. Conte adds 5 cases of maternal rubella from his own files following response to a questionnaire; congenital defects (ocular, cardiac and mental) resulted in the offspring in all cases. Four of these mothers acquired the disease in the first trimester, and the fifth had it in the seventh month. From another questionnaire sent to the mothers of 120 congenitally malformed children, Conte found that 4.2 per cent gave a history of rubella during pregnancy, a percentage figure ten times the actual case rate of maternal rubella for the childbearing age group in the population at large.

To start with the defective child and then to attempt to establish a history of maternal rubella is perhaps to put the cart before the horse. While such studies shed light on the problem and are of some value, they are subject to limitations. Much of the early work was conducted in this manner and is of necessity retrospective. The fundamental problem under consideration is not what percentage of congenital defects are the result of rubella but rather what percentage of mothers acquiring the disease during pregnancy give birth to children with congenital defects.

Scant data are available on the percentage of women who had rubella during pregnancy, especially the first trimester, who subsequently gave birth to normal children. Fox and Bortin[5] attempted to determine the numerical probability of congenital anomalies following rubella during pregnancy. They found that of 152 married women who contracted rubella in Milwaukee, Wis., during the period 1942-1944, 11 had the malady during pregnancy; 5 during the first two months, 4 during the third and fourth months, 1 in the seventh month and 1 in the ninth month. One of the five who contracted the disease in the first two months of pregnancy subsequently had a stillborn infant. The remaining 10 had normal children.

Aycock and Ingalls[6] investigated 1,300 cases of rubella in Massachusetts and found that 4 occurred during pregnancy. Two were in the second month, 1 in the fourth and 1 in the ninth. One baby whose mother had rubella in the second month exhibited evidence of mental retardation. The other 3 were normal.

Questionnaires were sent by Ober, Horton and Feemster[7] to women between 17 and 49 years of age who had rubella in 1943 as reported to the Boston Department of Public Health. Fifty-four of some 3,000 women reported that they had contracted the disease while pregnant. Infants with abnormalities were observed in 8 of these cases and abortions or stillbirths in 9. Eleven of the 17 abnormal pregnancies were in women who contracted rubella during the first trimester. Since 22 of the group of 54 pregnant women suffered from the disease in the first trimester, the 11 abnormal pregnancies from this total of 22 represents an incidence of 50 per cent lost or defective.

In response to another type of questionnaire sent by the same workers, of 9 pregnancies complicated by rubella physicians reported that only 3 produced normal infants. Eight of the 9 women contracted rubella in the first trimester.[7]

## METHOD

This study was made in the hope that the accumulated data might be helpful as an index of the numerical probability of congenital defects in children born of mothers who had rubella during pregnancy. A request was made to all such women through the facilities of a syndicated health column. They were asked to indicate the period of gestation in which the ailment appeared and the outcome relative to the child. In this way it was hoped to ascertain how many normal and how many abnormal youngsters were delivered.

## ANALYSIS OF DATA

The figures in tables 1 and 2 include information received in eighty-two letters concerning 84 babies. (There were two sets of twins.) Three children were stillborn; all the mothers had the disease in the first trimester of pregnancy. Of the 81 living children, 25 were normal and 56 were abnormal. The accumulated data are shown in terms of the several defects reported with reference to the trimester in which the mother acquired rubella.

Of the 56 living abnormal infants, 36 had a single defect and 20 had multiple defects. It is interesting to note that in 18 of the latter instances, the mother had the disease in the first trimester. In histories of 44 (78.6 per cent) of the abnormal living infants, the mother told of having rubella in the first trimester; the mothers of 8 infants (14.3 per cent) acquired the disease in the second trimester; in 1 questionable case (1.8 per cent) it was acquired in the last trimester. In 3 cases (5.3 per cent) the period of gestation was unknown.

* This child had cerebral infantile diataxia probably not associated with maternal rubella.

TABLE 2.—*Relation of Congenital Defects After Rubella to Trimester of Pregnancy*

| | Trimester | | | Stage of Gestation Unknown |
|---|---|---|---|---|
| | First | Second | Third | |
| Cataracts | 17 | 0 | 0 | 0 |
| Congenital heart disease | 17 | 1 | 0 | 1 |
| Deafness | 12 | 1 | 0 | 1 |
| Malformed teeth | 3 | 2 | 0 | 0 |
| Mental defects | 7 | 0 | 0 | 0 |
| Spina bifida and hydrocephalus * | 3 | 0 | 0 | 0 |
| Congenital gastrointestinal defects | 2 | 1 | 0 | 0 |
| "Blindness" | 1 | 2 | 0 | 1 |
| Miscellaneous | 11 | 2 | 0 | 1 |

* There was 1 additional infant with spina bifida alone (first trimester).

The defects described in order of frequency were congenital heart disease (19), congenital cataracts (17), deafness (14), mental deficiency (7) and malformed teeth (5). Gastrointestinal, spinal and skeletal defects occurred in lesser numbers.

The one abnormality reported as following rubella in the third trimester of pregnancy was cerebral palsy. This condition was not considered to be associated with the mother's illness.

In summary, 87 per cent of the babies born of mothers having rubella during the first trimester of pregnancy were abnormal, as were 42 per cent of those born in the second trimester; probably none in the third was abnormal.

## COMMENT

It is realized that this method of collecting data has numerous drawbacks and limitations and that any evaluation of such statistics must be made with caution. The results reported in the many letters depend to a large degree on the patient's memory. The accuracy of diagnosis in some instances is open to question. The proportion of normal to abnormal children is perhaps not strictly accurate because it is probable that some mothers with normal offspring either do not remember having had rubella or were not sufficiently impressed with the significance of the ailment to respond. The parent of a subsequently defective child is much more likely to respond. This is further substantiated by the fact that many of the mothers whose children were abnormal told of looking back into their pregnancy to search for a cause. The increased response by women having rubella in the first trimester is probably not indicative of a greater incidence of the disease during this time but rather a reflection of more pointed interest in this group in which abnormalities are more prone to occur.

The data are nevertheless presented as is and cannot be disregarded totally because of the consistency and general agreement with the several reports in the literature. The appearance of congenital heart disease, cataracts, deafness, mental deficiencies and malformed teeth in such large incidence is noteworthy, and the relationship to the occurrence of maternal rubella in the first trimester of pregnancy is striking. This is in keeping with previous reports and is surely significant.

The caliber of the letters received was surprising and worthy of comment. The majority were written intelligently and included considerable detail. Only a few (10) were rejected because of incomplete and confusing facts. Many were written by persons with a professional background. But accurate evaluation of this problem must await further study of cases in which the diagnosis has been established and the detail of subsequent developments carefully recorded.

However, in the light of the evidence that already has accumulated, one might question the propriety of permitting such results to accumulate in the future. At least the high percentage of congenital anomalies following maternal rubella in the first trimester is disturbing enough to warrant consideration of therapeutic curettage in these cases. The evidence in this article supports those who advocate abortion, although such a recommendation must always be made with caution. The situation should be explained to all prospective parents, who must be given an opportunity to share in the responsibility of deciding whether or not the pregnancy ought to be terminated. If the percentage of congenital defects is found to even approximate the figures that available reports indicate, the family and society in general would be better off if pregnancies in mothers having rubella in the first trimester were terminated early.

## SUMMARY

1. Eighty-two letters concerning 84 babies are the basis for a survey to establish the incidence of normal and abnormal infants following maternal rubella with reference to the trimester in which the disease was acquired and the specific defects in the abnormal infants.

2. The principal anomalies noted were congenital heart disease (19), congenital cataracts (17), deafness (14), mental deficiency (7) and malformed teeth (5).

3. Eighty-seven per cent of babies born of mothers having rubella in the first trimester were abnormal, 42 per cent in the second and probably none in the third.

4. The disadvantages and inaccuracies of the method and the data are admitted but the high percentage of abnormalities in children whose mothers had rubella the first trimester is significant of a correlation between congenital defects and maternal rubella.

5. The advisability of therapeutic abortion is raised. As yet no hard and fast rule can be made, and this important decision still awaits additional critical study. It is believed that all prospective parents should be acquainted with the background of the problem and given an opportunity to share in the decision relative to curettage.

## TRICHINOSIS AS A CAUSE OF MAJOR ARTERIAL THROMBOSIS

JEROME A. COVEY, M.D.
Ridgewood, N. Y.

JEREMIAH J. McMAHON, M.D.
Roslyn, N. Y.

*and*

HARVEY L. MYERS, M.D.
Cedarhurst, N. Y.

Arteriosclerosis obliterans and thromboangiitis obliterans are most commonly the causes of thrombosis in large arteries. Less frequently certain specific forms of arteritis due to syphilitic, rheumatic and acute infections, of which typhoid, typhus and influenza are examples, may result in thrombosis of major arteries in the lower extremities. Trauma, ergotism and certain blood dyscrasias such as polycythemia vera[1] must also be considered in the etiologic analysis of arterial thrombosis. Nygaard and Brown[2] describe idiopathic simple arterial thrombosis. Such additional etiologic agencies as chronic ulcerative colitis,[3] hypertensive cardiovascular disease and congestive failure have been described in the literature as rare causes.

Trichinosis has been considered as a potential source of arterial thrombosis. Kilduffe and others[4] describe a case of femoral arterial thrombosis resulting in gangrene and amputation of an extremity about seventeen days after the onset of the disease. Dr. Kilduffe believed that the trichinosis and femoral arterial thrombosis in this case represented simply a fortuitous coincidence. Dr. Barbash, one of the junior authors, maintained that it was possible that a direct causal, although inexplicable, relation existed between the trichinosis and the circulatory occlusion. Thrombosis of small vessels in trichinosis is well established.[5] However, references to major arterial thrombosis complicating trichinosis are infrequent. The following cases, one of which exhibited this relationship, are reported to further establish the fact that major arterial thrombosis may be a complication of trichinosis.

### REPORT OF CASES

CASE 1.—*History and Course.*—Mrs. A. V., a white woman, aged 54, was admitted to the medical service of Queens General Hospital on April 15, 1947, complaining of abdominal pains of two weeks' duration. The onset had been fairly sudden with epigastric pain followed by belching, diarrhea, nausea and vomiting. The pain was well localized and would come on about two hours after meals. A tarry stool was noted on one occasion two days before admission, but there was no blood in the vomitus. Increasing lassitude and fever had also been present. Physical examination revealed essentially normal conditions, and the true nature of the case did not become evident until the husband was hospitalized. The wife died several days before the husband.

CASE 2.—*History.*—Mr. L .V., a white man aged 59, a fur cutter born in Hungary, entered the hospital complaining of sore throat, dyspnea and weakness. Two weeks prior to admission he had a bout of severe diarrhea which lasted five days and left him extremely weak. The past and family histories were noncontributory.

*Physical Examination.*—The patient was well developed and well nourished, alert and cooperative, although obviously acutely ill and weak. The blood pressure was 110 mm. of mercury systolic and 70 mm. diastolic. The respiratory rate was 24 per minute, and breathing was somewhat labored. The temperature was elevated to 103.2 F., and the pulse was regular in rate but rapid, 120 per minute. There were moist rales at the base of both lungs. The heart was not enlarged or displaced. No murmurs or thrills were elicited. The abdomen was round, soft, nonrigid and nontender; the liver and spleen were not palpable. There was no edema of the face or extremities. There were no obvious areas of muscular tenderness. Except for hypoactive deep reflexes, the neurologic examination revealed normal conditions. The ocular fundi were essentially normal, exhibiting only a moderate tortuosity of the vessels. Rectal examination revealed moderate prostatic hypertrophy.

*Course and Treatment.*—During the first week of hospitalization there was a gradual decline in temperature but some increase in weakness. During the second week the temperature again began to rise. The patient complained of severe pain in the left calf and exhibited tenderness to pressure of the calf muscles and a positive Homan's sign on the left. A circumscribed swollen area with bluish discoloration of the skin appeared over the anterior surface of the left tibia. The left foot became cold and painful. The right lower extremity then also became pale and cold. The most distal palpable pulses in both lower extremities were those of the femoral arteries. Both legs became cold below the knees. The discolored area on the skin of the left leg increased in size rather rapidly. The administration of blood transfusions, penicillin, streptomycin and dicumarol® failed to avert gangrene. Within four days after the first appearance of the circumscribed area on the left leg, gangrene had developed in all the toes of the left foot. There was a line of demarcation just above the ankle. The patient's general condition deteriorated rapidly. Left supracondylar amputation was considered, but it was believed that the patient could not survive such a procedure. The right foot then became mottled in addition to being cold, pale and painful as previously noted. Also at this time (the end of the second week) there appeared in the right ocular fundus multiple flame-shaped hemorrhages. In order to alleviate the severe pain, both lower extremities were packed in ice. This measure succeeded in keeping the patient comfortable until he expired on May 17, three weeks after admission to the hospital, five weeks after the onset of the illness.

*Laboratory Examinations.*—Three blood cultures were sterile. Agglutination tests for typhoid O and H, paratyphoid A and B, and Brucella abortus and Proteus 0 X 19 antigens were negative on two occasions. Reactions of the blood to Wassermann and Kline tests were negative. Examination of the spinal fluid revealed normal composition. Several urine cultures were sterile. Hematologic studies revealed a polymorphonuclear leukocytosis with a shift to the left, no anemia and a normal number of eosinophils on six successive blood counts. Shortly before the death of the patient a positive Trichinella precipitin test in a 1:640 dilution was obtained. It is to be noted that a Trichinella precipitin test taken early in the course of the illness had been negative. The electrocardiogram was essentially normal.

### COMMENT

The onset of the acute illness and clinical course were similar in both husband and wife, except for the complicating thrombosis and gangrene in the husband. It is interesting to note that the wife had an immediate positive precipitin test for trichinosis in a 1: 1,280 dilution and a consistent eosinophilia averaging on several counts 10 per cent. Trichinosis was subsequently proved at postmortem examination by the finding of Trichinella cysts in various stages of encapsulation in numerous sections taken from the skeletal musculature and diaphragm of each patient.

In addition to Trichinella cysts, examination of the tissues of the husband also revealed multiple infarcts in kidneys and spleen and parenchymatous degeneration of the liver. There was no evidence of arteriosclerosis or thromboangiitis obliterans in the peripheral vessels. There was thrombosis of the left femoral artery with gangrene of the lower extremity. Mural thrombosis was present in the aorta, and there was thrombotic occlusion of the superior and inferior mesenteric arteries. Sections of tissue from the diaphragm and leg muscle were examined for Trichinella and showed recent infestation. The organisms were not discovered in the walls of the femoral artery, in the thrombus itself or in the periarterial tissues. The significant finding after a thorough search by means of serial sections for a specific lesion was a periadventitial leukocytic cellular infiltration with necrosis.

Perivascular leukocytic cellular infiltration was found consistently in sections taken from areas that demonstrated involvement of the vessel walls. In the neighborhood of actual vascular closure, the vessel walls appeared to be more deeply and heavily penetrated with this inflammatory infiltration. Serial sections of the vessels of the wife also demonstrated a perivascular infiltration, although not so extensively as that observed in the husband.

### SUMMARY

The observations suggest the mechanism of the production of arterial thrombosis in trichinosis. They also imply that had the process of infiltration of leukocytic cells continued in the first case, we might also have demonstrated clinical evidence of vascular thrombosis. These observations are consistent with those described by Gould[5] as producing thrombi in smaller vessels.

### CONCLUSION

Two cases of trichinosis are reported, 1 of which demonstrated massive gangrene of the left lower extremity resulting from thrombosis of the femoral artery. When thrombotic occlusion occurs in a major artery, trichinosis should be considered as a possible etiologic factor.

## RECOVERY FOLLOWING AN OVERDOSE OF PYRITHYLDIONE (PRESIDON®)

ROBERT M. ROSE, M.D.
and
RICHARD J. MARCHAND, M.D.
Buffalo

In recent months a new sedative-hypnotic drug, pyrithyldione (presidon,® 3,3-diethyl-2, 4-dioxotetrahydropyridine) has been made available for clinical use. Extensive studies of its pharmacology were reported in 1940 by Koppanyi and co-workers,[1] who concluded that the drug appeared to afford certain advantages over the barbiturates. On the basis of this work, subsequent investigators,[2] using therapeutic dosages in human subjects, concluded that the drug was an effective hypnotic and sedative which was distinguished by excellent tolerability. To our knowledge, the following case is the first reported instance of overdosage and intoxication attributable to pyrithyldione.

### REPORT OF CASE

A semicomatose white woman aged 27 was admitted to the Buffalo General Hospital May 5, 1949. She had previously been under the care of a psychiatrist, who found her anxious and depressed, while manifesting suicidal tendencies and many somatic symptoms. Either nursing care or hospitalization was recommended but was refused. It was presumed that the patient ingested twenty-four tablets (4.8 Gm.) of pyrithyldione some time during the eight hours prior to admission. The initial treatment consisted of 5 cc. of nikethamide solution 25 per cent given intravenously thirty minutes before admission. Physical examination on entry to the hospital revealed a pale, young adult woman of 106 pounds (48 Kg.) who responded only to painful stimuli. The rectal temperature was 97 F., the pulse rate was 100 and the blood pressure was 80 systolic and 60 diastolic. Respirations were shallow and the rate was 16 per minute. Neurologic examination revealed the following: pupils were equally constricted and reacted sluggishly to light; corneal and gag reflexes were present bilaterally. The deep tendon reflexes were active and equal except for absent knee and ankle jerks on the right. Pathologic reflexes were not elicited.

The stomach was lavaged and about 300 cc. of clear yellow fluid which contained a notable amount of whitish sediment was obtained. Intramuscular caffeine sodium benzoate (0.5 Gm.) and intravenous fluids were administered. One hour after admission the patient began to respond. The blood pressure rose to 108 systolic and 70 diastolic. The pupils became dilated and reacted well to light. The deep tendon reflexes returned. At the end of another hour thrashing movements of the extremities were observed. Five hours after admission the patient was still lethargic but answered questions. Nine hours after admission recovery was complete. Results of laboratory tests were as follows: Urinalysis revealed a rare red cell and 3 to 5 white cells; the specific gravity was 1.006. The hemoglobin level of the blood was 12.8 Gm.; the red blood cell count was 4,400,000 and the white count 14,000 with 75 per cent polymorphonuclear leukocytes. The blood urea nitrogen determination was 11 mg. per hundred cubic centimeters.

### COMMENT

Animal experiments (rabbit and dog) have indicated that intoxication due to pyrithyldione (3,3-diethyl-2, 4-dioxotetrahydropyridine) produces a progressive clinical state similar to that caused by the barbiturates. The initial response to pyrithyldione in large dosage is muscular incoordination and staggering. Following this there appear increasing sensory loss, hypnosis, coma and death. However, nearly fatal doses of the drug fail to abolish the corneal reflex. A gradual fall in blood pressure ending in circulatory collapse and cessation of cardiac activity is observed, but only after respiratory failure. A moderate degree of bradycardia is noted. Respirations become slow and of decreasing amplitude. A fall in body temperature is proportional to the amount of drug administered. After repeated daily doses there is no significant change in the peripheral blood picture. The smallest oral dose to produce sensory depression and motor paralysis in rabbits is 250 mg. per kilogram of body weight, as shown by Koppanyi and co-workers[1]; the oral minimal lethal dose is 500 to 600 mg. per kilogram. Our experience indicates that nonlethal amounts in an adult patient closely parallel the known effect in animals. The patient experiences a rapid and complete recovery within nine hours with supportive therapy. The dose ingested in this case was equivalent to 100 mg. per kilogram. This is much less than that producing early signs of intoxication in animals (250 mg. per kilogram in rabbits). Therefore, we believe it should be emphasized that the degree of tolerance in adult patients is probably less than that in animals. However, despite this apparently lessened tolerance in adult patients, the margin of safety remains relatively wide.

## REPORT TO THE COUNCIL

*The Council has authorized publication of the following statement from the Therapeutic Trials Committee, a standing committee of the Council on Pharmacy and Chemistry.*

Austin Smith, M.D., *Secretary.*

## ESTROGENS AND ANDROGENS IN MAMMARY CANCER

### A Progress Report

*In the fall of 1947 the Therapeutic Trials Committee undertook the sponsorship of a cooperative investigation of the effects of steroid hormones in the treatment of mammary cancer. This investigation, coordinated by a Subcommittee composed of Dr. Ira T. Nathanson, Massachusetts General Hospital, Boston, Chairman; Dr. Frank E. Adair, Memorial Hospital, New York; Dr. Williard Allen, Washington University of St. Louis, and Dr. Earl T. Engle, Columbia University, New York, has been proceeding for approximately eighteen months. On April 4 to 7, 1949, a conference of the investigators participating in this study*[1] *was held in Chicago, at which time the results of the coordinated studies were reviewed and recommendations made for future studies. This report summarizes the conclusions of the conference, which must be regarded as tentative and subject to revision as further experience accumulates. A full report of the conference will be made available in the near future to interested workers in this field.*

Walton Van Winkle Jr., M.D., *Secretary.*

The work of other investigators which led to the institution of the present cooperative study of steroid hormones in mammary cancer has been reviewed in a previous report.[2] In the present study, there are several objectives: (1) to define the precise role of steroid hormone therapy in advanced mammary cancer; (2) to determine the dosage levels of testosterone propionate considered optimum for adequate subjective and objective response; (3) to determine whether any differences in response occur with the use of different estrogens, and the optimum dosage of each, and (4) to investigate the mechanism of hormone action through a study of the biochemical, metabolic and histologic changes produced in the normal and pathologic tissues of the body.

#### PLAN OF STUDY

Four dosage schedules of testosterone propionate were selected for investigation, as follows:

Schedule A: 25 mg. three times weekly
Schedule B: 50 mg. three times weekly
*Schedule C: 100 mg. three times weekly*
Schedule D: 200 mg. three times weekly

Each investigator was encouraged to use schedule C on half of those patients selected for androgen therapy and one of the other three schedules on the remaining patients. The duration of therapy was left to the discretion of the investigator.

Six different estrogens were selected for study, and the dosage of each was established by the Subcommittee on the basis of available data on relative estrogenic potency in the human being. The estrogens and dosages used were as follows:

Diethylstilbestrol, 15 mg. daily
Ethinyl estradiol, 3 mg. daily
Premarin,® 30 mg. daily
Estradiol dipropionate, 5 mg. two times weekly (intramuscularly)
*Dienestrol, 15 mg. daily*
Dimethyl ether of diethylstilbestrol, 30 mg. daily

Each investigator was urged to use diethylstilbestrol on half of those patients suitable for estrogen therapy and to choose one of the other five estrogens for use in the remaining patients.

*Selection of Cases.*—It was suggested that testosterone propionate be used in patients of any age whose predominant metastatic lesions were osseous. Estrogen was suggested for patients over 60 years of age with predominantly soft tissue lesions. In some instances, at the discretion of the investigator, these recommendations were altered.

No patient was to be given steroid hormone therapy whose disease might be amenable to other forms of therapy, principally surgery or irradiation.

#### PRELIMINARY RESULTS

On March 1, 1949, approximately 750 case reports had been submitted to the Committee for review, of which 476 cases had had at least one follow-up report filed. Of these, 36 had received combined therapy with both estrogens and androgens and were not suitable for analysis, and 8 had been treated prophylactically after operation.

*Testosterone Propionate.*—A total of 285 patients with metastases were treated with testosterone propionate. Of these 77 had only soft tissue lesions, 82 had only osseous lesions and 126 had both types. Approximately 62 per cent of these patients experienced subjective relief, which consisted principally of relief of pain, feeling of well-being and increased appetite.

Objective improvement in soft tissue lesions was seen in approximately 1 out of 5 patients, while objective improvement in osseous lesions was slightly less frequent, only 18 per cent of patients showing favorable response.

The data available did not reveal any alteration of response in the various age groups, although the age of the patients varied from 25 to 79 years. Interestingly enough, there appears to be little or no difference in response among patients receiving the various dosage schedules of testosterone propionate. Too few patients received schedule A to permit conclusions to be drawn regarding the effectiveness of this dosage schedule. However, no significant difference in response to schedules B, C or D was found, and it was concluded that no real advantage was obtained by the use of doses over 150 to 300 mg. weekly.

From the point of view of total dose, the data suggested that for the maximum response, somewhat more than 3.0 Gm. of testosterone propionate should be administered. This was particularly true from the point of view of subjective response—only 33 per cent of the patients receiving less than 3.0 Gm. showed subjective improvement, whereas 73 per cent receiving more than 3.0 Gm. had relief of symptoms. A similar, though lesser, difference in objective response of both soft tissue and osseous lesions was seen in those patients receiving more than 3.0 Gm. total dose as compared with those receiving less.

The duration of therapy, as might be expected, influenced the response to testosterone both from the point of view of relief of symptoms and objective improvement. Only 32 per cent of patients with soft tissue lesions received relief of symptoms with less than two months' therapy, whereas 65 per cent received relief after more than two months' treatment. Patients with osseous lesions, in which pain is a prominent factor, showed relief somewhat sooner, 80 per cent having some degree of relief after one month's treatment and only 30 per cent obtaining relief after treatment of less than one month's duration.

[2] Estrogens and Androgens in Mammary Cancer, Report of the Council on Pharmacy and Chemistry, J. A. M. A. **135:** 987 (Dec. 13) 1947.

An observation of interest was that, from the point of view of objective response, soft tissue lesions might show favorable responses after one month's therapy whereas the majority of osseous lesions which showed regression did not respond until after the fifth month of treatment.

It is yet too early to discuss with any accuracy the duration of either subjective or objective improvement following either androgen or estrogen therapy. It might be mentioned that approximately 20 per cent of testosterone-treated patients showing benefit have had improvement lasting for nine months or more. Many other patients have not received treatment for a sufficiently long period to determine the duration of their improvement.

*Estrogens.*—A total of 144 patients with metastases have been treated with estrogens, of which 92 were treated with diethylstilbestrol. Too few patients have as yet been treated with other estrogens to permit any conclusions being drawn regarding possible differences between them. Furthermore, the majority of patients were treated for soft tissue metastases and sufficient data on osseous lesion response is not now available. It may be said, however, that osseous lesions have been observed to respond favorably to estrogen therapy.

Approximately 60 per cent of patients treated with estrogens showed some degree of subjective relief of symptoms. About half the patients with soft tissue lesions showed objective improvement after estrogen therapy. There was a suggestion, in the relatively incomplete data, that patients over 60 years of age responded more favorably than those in the younger age groups, but, because of suggestions made to participants regarding selection of patients for treatment with estrogen, many more patients over 60 than under 60 were treated.

The results with diethylstilbestrol were better in those patients receiving a total dose of 2.0 Gm. or more. Also, a greater number of patients responded subjectively to diethylstilbestrol therapy after two months and objectively after five months of therapy than did those treated for lesser periods of time.

The duration of response to estrogen therapy is still undetermined, but about 25 per cent have maintained subjective and objective improvement for nine months or longer.

*Side Effects.*—Side effects from steroid therapy have been frequent and, at times, unpleasant. The most prominent side actions of testosterone are hirsutism, voice changes, increased libido and edema. These effects usually appear some weeks or months after the start of therapy. Hypercalcemia has been observed in a number of cases and occasionally has reached dangerous proportions. Several patients with severe hypercalcemia have been successfully treated with intravenous infusions of 2.5 per cent sodium citrate solution. This treatment should be used only if the hypercalcemia threatens the patient's life. It appears imperative that patients receiving testosterone be watched carefully for signs of hypercalcemia. Edema is also a potentially dangerous complication. Testosterone causes salt retention and may precipitate cardiac failure in elderly patients or patients with preexisting heart disease. This may be combated with a low sodium diet and diuretics.

Estrogens have produced nausea, uterine bleeding (usually when withdrawn), edema and other complications of cardiac failure. At times the nausea, often accompanied with vomiting, was sufficiently severe to require discontinuance of therapy. Occasionally, trial with a different estrogen overcame this difficulty.

All reactions occurred sufficiently frequently to stimulate a search for compounds having the desired therapeutic action with diminished incidence of unpleasant side effects.

### FUTURE STUDIES

The purpose of the conference of investigators was to correlate the information so far obtained in the investigation and to plan the direction of further studies. It became apparent that there were definite gaps in the data obtained and that certain areas of investigation should be explored more intensively. The conference agreed that the lower dosage schedules of testosterone propionate should be studied more adequately and that the estrogens other than diethylstilbestrol should be given more extensive trial. It was also agreed that the site or type of lesion should not necessarily be used as criteria for selection of cases for either androgen or estrogen therapy. Rather, it was decided that for the time being testosterone could be used in any patient whereas estrogens should be used only in patients at least five years following natural cessation of uterine bleeding, regardless of chronologic age.

An analysis of the data revealed that previous castration or irradiation therapy was confusing the appraisal of the results of steroid therapy in those instances where castration had been done or roentgen rays had been administered immediately prior to institution of hormone therapy. It was emphasized that if a patient could possibly receive benefit from castration or roentgen therapy, or further surgical treatment, the patient should not be given steroid hormones. Only those cases in which other methods of treatment had failed or were not feasible and in which surgical or irradiation castration had not been performed nor roentgen rays administered within the previous six months would be utilized for this investigation.

It was also agreed that greater emphasis must be placed on carefully controlled metabolic and biochemical investigations of selected cases.

The observation that steroid hormone therapy decidedly alters the metabolism of calcium, phosphorus and nitrogen, in both normal and cancerous patients, requires more intensive investigation. The significance of these alterations in blood and tissue chemical content with respect to the response of the tumor to steroid therapy is not apparent at this time, but these alterations suggest lines of attack on the general problem of mechanism of action.

The steroids also may produce profound changes on the hematopoietic system, as evidenced by the dramatic response of severe, refractory anemias in patients with metastatic breast cancer to testosterone therapy. No satisfactory explanation of this observation is yet available, and, although the effect may be immediately beneficial, the question of the ultimate result of such profound stimulation of the blood forming organs needs investigation.

Failures of therapy as well as successes also need intensive study from all aspects mentioned.

*Pathologic Material.*—By arrangement with the American Registry of Pathology at the Army Institute of Pathology, in Washington, D. C., biopsy and autopsy specimens and roentgenograms are being centralized for review by a group of consultants. The consultants in pathology are: Dr. Lauren V. Ackerman, Washington University of St. Louis; Dr. Fred Stewart, Memorial Hospital, New York, and Dr. Arthur Purdy Stout, Columbia University, New York. A preliminary review of the accumulated material by these consultants indicated a need for a careful study of tissue collected before, during and after treatment with the steroid hormones. Investigators were urged, therefore, to submit serial biopsy specimens from suitable patients treated with androgens or estrogens.

In addition to the possible determination of changes on the tumor tissue by the steroid hormones, this study presents an excellent opportunity to determine the effects of these substances on otherwise normal body tissues: skin, hair, follicles and other endocrine glands.

*Roentgenograms.*—The consultants in radiology, consisting of Dr. L. Henry Garland, San Francisco Hospital, San Francisco; Dr. Leo G. Rigler, University of Minnesota, Minneapolis, and Dr. Merrill Sosman, Peter Bent Brigham Hospital, Boston, have been asked to review and appraise the radiographic changes in lung and bone lesions following steroid therapy. Under the plan instituted by the conference each consultant will review the roentgenograms sent him by participating investigators in his geographic area. Significant roentgenograms will be selected by the consultants for duplication and collection at the Army Institute of Pathology. It was agreed that all cases should have a radiographic survey every three months after the start of therapy.

## LUPULON, AN ANTIBIOTIC FROM HOPS

The antibacterial properties of hops (Humulus lupulus) have been recognized for many years in connection with their use in brewing. From a petroleum ether extract an active principle, "lupulon," is readily crystallized.[1] Brewers[2] report that lupulon is 29,000 times more effective than phenol in restricting acid production by Lactobacillus bulgaricus. Added to agar or to Dubos' liquid medium,[3] lupulon inhibits the growth of most common fungi and many gram-positive bacteria; it also inhibits several acid-fast organisms, including the tubercle bacillus.

Chin[4] and associates of the Division of Experimental Therapeutics, University of California, have tested the therapeutic effects of lupulon on experimental tuberculosis in mice. Samples of crystalline lupulon were titrated for their in vitro effects on Mycobacterium tuberculosis. Added in serial dilutions to Dubos' fluid medium, each sample inhibited the growth of the H37Rv strain of the tubercle bacill[illegible] dilutions as [illegible]

At the end of thirty days a comparison of the tuberculosis severity was made between the treated and untreated groups. The group treated with intramuscular injections of lupulon showed a severity reduction ratio of 34 to 1 for the liver, 8 to 1 for the heart and 4 to 1 for the lungs and spleen. The two orally treated groups showed a severity reduction ratio of 10 to 1 for the liver and spleen, 5 to 1 for the lungs, 3 to 1 for the heart and 2 to 1 for the kidneys. The average therapeutic effect in the three treated groups was a 4 to 1 reduction in the severity of tuberculosis in all tissues and organs.

Histologic examinations showed that lupulon given intramuscularly in the selected dose produces some foci of degeneration in the renal tubules. Pathologic changes, however, were not observed in mice given the selected oral dose.

Chin attributes the definite tuberculostatic action of lupulon largely to its fat solubility, which enables it to be absorbed by the lipid fraction of the tubercle bacillus. Whether or not lupulon is also tuberculolytic has not been determined.

## RADIATION CATARACTS

As early as 1897[1] physicians knew that roentgen rays could damage some structures of the eye. Unequivocal demonstration of cataract formation in the lens of the irradiated immature kitten was made eight years later.[2] Since that time the entity of radiation cataract has been well established, both clinically and experimentally.[3] Even after the lapse of half a century, the data available are at best qualitative, and many unanswered questions remain as to dosage, species differences and individual variations in biologic susceptibility. Roentgen rays exert their major damage on the dividing cells of the lens equator, and this damage provides the nidus for the slowly developing, progressive lenticular opacities which appear, most characteristically in the posterior subcapsular region.[4]

Recently the development of cataracts in young which the control just turns the power on shall be recorded. The temperature at which the covering is energized 100 per cent of the time shall also be recorded. The difference in these room temperatures shall be considered the adequacy range of the covering and controller.

4. The wattage input to the covering shall be such and so regulated that the average temperature between the sheets of a standard bed shall not be lowered more than 1.8 degrees C. (3.3 degrees F.) for each 5.5 degrees C. (10.0 degrees F.) lowering in ambient within the recorded adequacy range of the covering, and when used in accordance with the manufacturer's recommendations. This lowering of bed temperature shall not exceed 5.5 degrees C. (10.0 degrees F.) in any case, regardless of adequacy range.

5. The manufacturer shall furnish to the Council a copy of its guaranty to the purchaser.

6. There shall accompany each covering clearly written instructions for its use.

7. The manufacturer shall give evidence that adequate facilities for servicing the covering are available and shall furnish names and addresses of servicing agencies.

8. The electrically heated bed covering shall be so constructed that it can be laundered by normal methods either at home or at a commercial laundry. Instructions for such laundering shall be part of the literature supplied with the covering.

9. Therapeutic claims, if any, shall be clearly stated in the literature accompanying the bed covering when sold. Conclusive evidence shall be submitted to substantiate the therapeutic claims. The manufacturer shall supply with the covering submitted for acceptance, data obtained in his own laboratory or in a recognized independent laboratory to support any specific claims which he may make for the device.

10. The sizes of wired area of the electrically heated bed coverings shall conform to one of the standard mattress sizes. The wired area shall not be more than 178 cm. (70 inches) long and of a width to conform, within a tolerance of plus or minus 5 cm. (2 inches), to the sizes given in the following table:

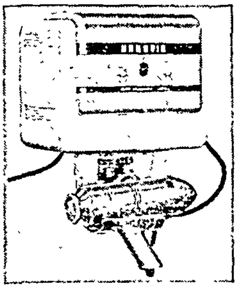
| | |
|---|---|
| Single bed | 91 cm. (36 inches) |
| Twin bed | 99 cm. (39 inches) |
| Three-quarter bed | 122 cm. (48 inches) |
| Double bed | 137 cm. (54 inches) |

11. The maximum bed temperature obtainable with control at "High" position under any condition of ambient temperature shall not exceed 108 F. (42 C.).

## WALL MODEL AERO-KROMAYER LAMP ACCEPTABLE

Manufacturer: Hanovia Chemical & Manufacturing Company, Chestnut Street & N. J. R. R. Avenue, Newark 5, N. J.

The Wall Model Aero-Kromayer Lamp is a source of ultraviolet radiation so designed that the control box is supported on a wall bracket and connected by a cable with the lamp and lamp housing. The lamp is held in the hand of the physician as he applies the radiation to the patient.



Hanovia Wall Model Aero-Kromayer Lamp

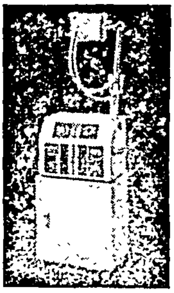
The construction of the lamp itself and the quality of its radiation were described in The Journal (117: 451 [Aug. 19] 1941) in the announcement of acceptance of the Hanovia Aero-Kromayer Lamp, Models S-2202 and S-2203. The present model differs only in the mounting of the control box and the housing of the lamp. Convincing evidence was obtained by the Council that the specimen furnished by the manufacturer had the physical properties and output claimed for it.

The Council on Physical Medicine and Rehabilitation vote to include the Wall Model Aero-Kromayer Lamp in its list o accepted devices.

## FISCHER TABLE MODEL 200 SHORT WAVE DIATHERMY UNIT ACCEPTABLE

Manufacturer: H. G. Fischer & Company, 9451-91 W. Belmont Avenue, Franklin Park, Ill.

The Fischer Table Model 200 Short Wave Diathermy Unit is intended for applying heat to the tissues and is designed to generate wavelengths of approximately 11 meters (corresponding to 27.12 megacycles) without the use of crystal control. It differs from the previously accepted Model 400 in size, being small enough to set on a table.



Fischer Table, Model 200 Short Wave Diathermy Unit

The height, width and length of the cabinet are 86, 86 and 51 cm. (34, 34 and 20 in.), respectively, and the weight is 47 Kg. (103 pounds). The domestic shipping weight is 78 Kg. (167 pounds) and the foreign, 90 Kg. (197 pounds).

The apparatus operates on a 120 volt alternating current and draws about 10 amperes (900 to 1,200 watts). It has Type Approval (D-484) of the Federal Communications Commission, and a letter received directly from the Underwirters' Laboratories, Inc., under date of Feb. 10, 1949, certifies that Model 200 has been found acceptable for listing.

The apparatus was tested for output by the lamp-load method. The output of Model 200, as indicated by two 100 watt, 120 volt bulbs, was about 150 watts.

The Council on Physical Medicine and Rehabilitation voted to include the Fischer Table Model 200 Short Wave Diathermy Unit in its list of accepted devices.

## BELTONE SYMPHONETTE MODEL HEARING AID ACCEPTABLE

Manufacturer: Beltone Hearing Aid Company, 1450 West 19th Street, Chicago 8.

The Beltone Symphonette Model Hearing Aid is a three tube air conduction hearing aid with the batteries contained in the amplifier case. Bone conduction is also available. The front of the case is constructed of flesh-colored plastic material. The back is made of stainless steel, the lower half of it being hinged to give access to the battery compartments. The magnetic receiver (marked "H") is connected to the top of the amplifier case by means of a light plastic-covered cord which has dual pin plugs at each end. A single wheel-type combination "On-Off" switch and volume control is located on the upper right hand side of the amplifier case. A sliding contact "Hi-Lo" tone control switch is on the top of the case. An attachment clip is fastened to the front of the case.

The following data were obtained from a laboratory acceptable to the Council.

Dimensions: 92 by 56 by 22 mm. ($3\frac{5}{8}$ by $2\frac{3}{16}$ by $\frac{7}{8}$ inch).

Weight: Including amplifier case with batteries, 170 Gm. ($5\frac{15}{16}$ oz.). Receiver and cord weigh an additional 7 Gm. ($\frac{1}{4}$ oz.).

*Battery Drain Data:*

| | Measured Voltage | Measured Current |
|---|---|---|
| A, mercury cell — 1.3 volts | 1.25 volts | 40 ma. |
| B, zinc and carbon—22½ volts | 21.00 volts | 0.72 ma. |

*Maximum Acoustic Gain for Pure Tones:*

| Frequency, Cycles | Lo Tone Control Position, Decibels | Hi Tone Control Position, Decibels |
|---|---|---|
| 250 | 38 | 19 |
| 500 | 45 | 31 |
| 1,000 | 52 | 43 |
| 2,000 | 62 | 58 |
| 3,000 | 70 | 6 |
| 4,000 | 44 | |

Council on Physical Medicine and
e the Beltone Symphonette M
epted devices.

### CONCLUSIONS

Certain conclusions were reached by the Subcommittee on Steroids and Cancer as to the present status of estrogens and androgens in the treatment of advanced mammary cancer. These are:

1. There is now available for the treatment of breast cancer a third weapon in the form of steroid hormones.
2. Barring future developments, this weapon will prove useful in the treatment of those patients with extensive and distant lesions who, heretofore, have been beyond direct attack on the disease.
3. Surgical treatment and irradiation, singly or in combination, still must be considered the primary forms of treatment, steroid hormone therapy being reserved only for those cases in which orthodox methods cannot be applied or have proved unsuccessful.

This last point is of considerable importance, and the usefulness of properly administered roentgen irradiation and operation should not be overlooked in the present period of steroid research. *Roentgen irradiation in the control or palliative* treatment of inoperable breast cancer, and of recurrences or metastases, is of well established usefulness. Its employment in the treatment of inoperable primary lesions, local recurrences, regional lymph node metastases, most cases of bone metastases and selected cases of pulmonary, cerebral and other metastases will usually alleviate symptoms and prolong life. The side effects of irradiation, properly administered, are usually fewer and less severe than those of steroid therapy, at least up to the present date. Steroid therapy should, the participating investigators believe, be reserved, in everyday clinical practice, for patients in whom the possibilities of adequate surgical treatment and careful roentgen irradiation have first been fully utilized and have given clear evidence of being no longer of benefit. Use in this sequence is suggested as being the most logical method in the light of present information.

Finally, the conference brought a greater realization to all the participants of the complexities in the evaluation of the effects of steroid hormones in mammary cancer. In considering the direction of future investigations, the conference concluded that it was important to concentrate attention on a study of possible mechanisms by which the steroid hormones produce beneficial changes in the patient suffering from breast cancer. The fact that steroid hormones do produce changes provides a hitherto unavailable tool for the study of the growth and regression of cancer cells.

The work of the cooperating groups is being pursued actively along the lines indicated in this report, and further data will be presented from time to time as these become available.

## NEW AND NONOFFICIAL REMEDIES

*The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.*

Austin Smith, M.D., *Secretary.*

**CHOLINE DIHYDROGEN CITRATE** (See New and Nonofficial Remedies 1949, p. 425).

The following dosage forms have been accepted:

Abbott Laboratories, North Chicago, Ill.

**Tablets Choline Dihydrogen Citrate:** 0.65 Gm.

Walker Vitamin Products, Inc., Mount Vernon, N. Y.

**Capsules Choline Dihydrogen Citrate:** 250 mg.

**Tablets Choline Dihydrogen Citrate:** 500 mg.

**PENICILLIN** (See New and Nonofficial Remedies 1948, p. 148).

The following dosage forms have been accepted:

Hynson, Westcott & Dunning, Inc., Baltimore 1

**Tablets Aluminum Penicillin:** 50,000 units. Buffered with sodium benzoate 0.3 Gm.

Chas. Pfizer & Co., Inc., Brooklyn 6

**Crystalline Penicillin G Potassium:** 1,000,000 unit vials.

**SODIUM DEHYDROCHOLATE** (See New and Nonofficial Remedies 1949, p. 341).

The following dosage form has been accepted:

R. J. Strasenburgh Company, Rochester, N. Y.

**Solution Sodium Dehydrocholate 20%:** 5 cc. ampuls.

**STREPTOMYCIN** (See New and Nonofficial Remedies 1949, p. 159).

The following dosage form has been accepted:

Chas. Pfizer & Co., Inc., Brooklyn 6

**Streptomycin Sulfate:** 20 cc. vials containing streptomycin sulfate equivalent in activity to 5 Gm. and 10 Gm. of streptomycin base.

**SULFADIAZINE-U. S. P.** (See New and Nonofficial Remedies 1949, p. 134).

The following dosage form has been accepted:

Brewer & Company, Inc., Worcester 4, Mass.

***Tablets Sulfadiazine:*** *0.5 Gm.*

**TRIASYN B-U. S. P.** (See New and Nonofficial Remedies 1949, p. 553).

The following dosage form has been accepted:

Brewer & Company, Inc., Worcester 4, Mass.

**Gel-ets Triasyn B:** Each capsule contains 2 mg. of thiamine hydrochloride, 3 mg. of riboflavin and 20 mg. of nicotinamide.

# Council on Physical Medicine and Rehabilitation

## REPORTS OF THE COUNCIL

*The Council on Physical Medicine and Rehabilitation has authorized publication of the following report.*

Howard A. Carter, *Secretary.*

### REQUIREMENTS FOR ACCEPTANCE OF ELECTRICALLY HEATED BED COVERINGS

Electrically heated bed coverings (blankets, comforters, bed spreads, etc.) are designed for the comfort of the normal healthy sleeper and are not primarily for therapeutic purposes. Like the conventional blankets and comforters, however, electrically heated bed coverings may also be used by a physician in the management of illness.

The following requirements are for the attention of the manufacturers of electrically heated bed coverings and state the conditions under which the Council on Physical Medicine will accept the products:

1. To insure safety with respect to electric shock and overheating, the device shall be listed as approved by the Underwriters' Laboratories, Inc.
2. The name of the manufacturer, catalog identification and rating in watts and volts shall be permanently marked in a readily visible location on each covering and control. A covering intended for use on only alternating current shall be so marked, and if this usage is further limited to specific frequencies of alternating current, it shall also be so marked.
3. The adequacy range of the device shall not be less than 20 degrees F. (11 degrees C.) nor more than 35 degrees F. (19 degrees C.); i. e., the difference in room temperature between the point where zero power is supplied to the covering and where 100 per cent power is supplied to the covering may not be less than 20 degrees F. or greater than 35 degrees F.

In measuring adequacy range, the covering and controller shall be connected to rated voltage. The controller shall be set at midpoint position. The room temperature (which should be high enough at the start of the test to prevent any power input to the covering) shall be gradually lowered. The temperature at which the control just turns the power on shall be recorded. The temperature at which the covering is energized 100 per cent of the time shall also be recorded. The difference in these room temperatures shall be considered the adequacy range of the covering and controller.

4. The wattage input to the covering shall be such and so regulated that the average temperature between the sheets of a standard bed shall not be lowered more than 1.8 degrees C. (3.3 degrees F.) for each 5.5 degrees C. (10.0 degrees F.) lowering in ambient within the recorded adequacy range of the covering, and when used in accordance with the manufacturer's recommendations. This lowering of bed temperature shall not exceed 5.5 degrees C. (10.0 degrees F.) in any case, regardless of adequacy range.

5. The manufacturer shall furnish to the Council a copy of its guaranty to the purchaser.

6. There shall accompany each covering clearly written instructions for its use.

7. The manufacturer shall give evidence that adequate facilities for servicing the covering are available and shall furnish names and addresses of servicing agencies.

8. The electrically heated bed covering shall be so constructed that it can be laundered by normal methods either at home or at a commercial laundry. Instructions for such laundering shall be part of the literature supplied with the covering.

9. Therapeutic claims, if any, shall be clearly stated in the literature accompanying the bed covering when sold. Conclusive evidence shall be submitted to substantiate the therapeutic claims. The manufacturer shall supply with the covering submitted for acceptance, data obtained in his own laboratory or in a recognized independent laboratory to support any specific claims which he may make for the device.

10. The sizes of wired area of the electrically heated bed coverings shall conform to one of the standard mattress sizes. The wired area shall not be more than 178 cm. (70 inches) long and of a width to conform, within a tolerance of plus or minus 5 cm. (2 inches), to the sizes given in the following table:

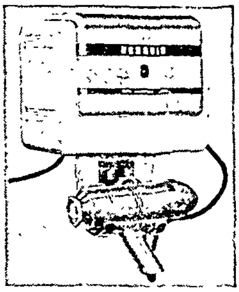
| | |
|---|---|
| Single bed | 91 cm. (36 inches) |
| Twin bed | 99 cm. (39 inches) |
| Three-quarter bed | 122 cm. (48 inches) |
| Double bed | 137 cm. (54 inches) |

11. The maximum bed temperature obtainable with control at "High" position under any condition of ambient temperature shall not exceed 108 F. (42 C.).

## WALL MODEL AERO-KROMAYER LAMP ACCEPTABLE

Manufacturer: Hanovia Chemical & Manufacturing Company, Chestnut Street & N. J. R. R. Avenue, Newark 5, N. J.

The Wall Model Aero-Kromayer Lamp is a source of ultraviolet radiation so designed that the control box is supported on a wall bracket and connected by a cable with the lamp and lamp housing. The lamp is held in the hand of the physician as he applies the radiation to the patient.



Hanovia Wall Model Aero-Kromayer Lamp

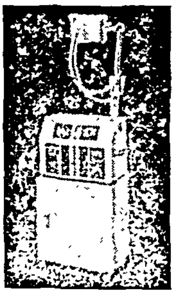
The construction of the lamp itself and the quality of its radiation were described in The Journal (117: 451 [Aug. 19] 1941) in the announcement of acceptance of the Hanovia Aero-Kromayer Lamp, Models S-2202 and S-2203. The present model differs only in the mounting of the control box and the housing of the lamp. Convincing evidence was obtained by the Council that the specimen furnished by the manufacturer had the physical properties and output claimed for it.

The Council on Physical Medicine and Rehabilitation voted to include the Wall Model Aero-Kromayer Lamp in its list of accepted devices.

## FISCHER TABLE MODEL 200 SHORT WAVE DIATHERMY UNIT ACCEPTABLE

Manufacturer: H. G. Fischer & Company, 9451-91 W. Belmont Avenue, Franklin Park, Ill.

The Fischer Table Model 200 Short Wave Diathermy Unit is intended for applying heat to the tissues and is designed to generate wavelengths of approximately 11 meters (corresponding to 27.12 megacycles) without the use of crystal control. It differs from the previously accepted Model 400 in size, being small enough to set on a table.



Fischer Table, Model 200 Short Wave Diathermy Unit

The height, width and length of the cabinet are 86, 86 and 51 cm. (34, 34 and 20 in.), respectively, and the weight is 47 Kg. (103 pounds). The domestic shipping weight is 78 Kg. (167 pounds) and the foreign, 90 Kg. (197 pounds).

The apparatus operates on a 120 volt alternating current and draws about 10 amperes (900 to 1,200 watts). It has Type Approval (D-484) of the Federal Communications Commission, and a letter received directly from the Underwirters' Laboratories, Inc., under date of Feb. 10, 1949, certifies that Model 200 has been found acceptable for listing.

The apparatus was tested for output by the lamp-load method. The output of Model 200, as indicated by two 100 watt, 120 volt bulbs, was about 150 watts.

The Council on Physical Medicine and Rehabilitation voted to include the Fischer Table Model 200 Short Wave Diathermy Unit in its list of accepted devices.

## BELTONE SYMPHONETTE MODEL HEARING AID ACCEPTABLE

Manufacturer: Beltone Hearing Aid Company, 1450 West 19th Street, Chicago 8.

The Beltone Symphonette Model Hearing Aid is a three tube air conduction hearing aid with the batteries contained in the amplifier case. Bone conduction is also available. The front of the case is constructed of flesh-colored plastic material. The back is made of stainless steel, the lower half of it being hinged to give access to the battery compartments. The magnetic receiver (marked "H") is connected to the top of the amplifier case by means of a light plastic-covered cord which has dual pin plugs at each end. A single wheel-type combination "On-Off" switch and volume control is located on the upper right hand side of the amplifier case. A sliding contact "Hi-Lo" tone control switch is on the top of the case. An attachment clip is fastened to the front of the case.

The following data were obtained from a laboratory acceptable to the Council.

*Dimensions:* 92 by 56 by 22 mm. (3⅝ by $2\frac{3}{16}$ by ⅞ inch).

Weight: Including amplifier case with batteries, 170 Gm. ($5\frac{15}{16}$ oz.). Receiver and cord weigh an additional 7 Gm. (¼ oz.).

*Battery Drain Data:*

| | Measured Voltage | Measured Current |
|---|---|---|
| A, mercury cell — 1.3 volts | 1.25 volts | 40 ma. |
| B, zinc and carbon—22½ volts | 21.00 volts | 0.72 ma. |

*Maximum Acoustic Gain for Pure Tones:*

| Frequency, Cycles | Lo Tone Control Position, Decibels | Hi Tone Control Position, Decibels |
|---|---|---|
| 250 | 38 | 19 |
| 500 | 45 | 31 |
| 1,000 | 52 | 43 |
| 2,000 | 62 | 58 |
| 3,000 | 70 | 68 |
| 4,000 | 44 | 44 |

The Council on Physical Medicine and Rehabilitation voted to include the Beltone Symphonette Model Hearing Aid in its list of accepted devices.

## LUPULON, AN ANTIBIOTIC FROM HOPS

The antibacterial properties of hops (Humulus lupulus) have been recognized for many years in connection with their use in brewing. From a petroleum ether extract an active principle, "lupulon," is readily crystallized.[1] Brewers[2] report that lupulon is 29,000 times more effective than phenol in restricting acid production by Lactobacillus bulgaricus. Added to agar or to Dubos' liquid medium,[3] lupulon inhibits the growth of most common fungi and many gram-positive bacteria; it also inhibits several acid-fast organisms, including the tubercle bacillus.

Chin[4] and associates of the Division of Experimental Therapeutics, University of California, have tested the therapeutic effects of lupulon on experimental tuberculosis in mice. Samples of crystalline lupulon were titrated for their in vitro effects on Mycobacterium tuberculosis. Added in serial dilutions to Dubos' fluid medium, each sample inhibited the growth of the H37Rv strain of the tubercle bacillus in dilutions as high as 1:40,000. Neither synergism nor antagonism occurred when lupulon was tested in the presence of other antituberculous substances, such as promin® (sodium p,p'-diaminodiphenyl-N,N'-didextrose sulfonate), streptomycin, subtilin or 2,3-dimercaptopropanol (BAL).

One hundred mice were infected intravenously with 0.02 mg. H37Rv strain of M. tuberculosis. Two groups of 20 mice each were set aside as controls. One group of 20 infected mice was given a daily intramuscular injection with 60 mg. lupulon, and two similar groups an intragastric dose of 150 mg. lupulon twice daily.

At the end of thirty days a comparison of the tuberculosis severity was made between the treated and untreated groups. The group treated with intramuscular injections of lupulon showed a severity reduction ratio of 34 to 1 for the liver, 8 to 1 for the heart and 4 to 1 for the lungs and spleen. The two orally treated groups showed a severity reduction ratio of 10 to 1 for the liver and spleen, 5 to 1 for the lungs, 3 to 1 for the heart and 2 to 1 for the kidneys. The average therapeutic effect in the three treated groups was a 4 to 1 reduction in the severity of tuberculosis in all tissues and organs.

Histologic examinations showed that lupulon given intramuscularly in the selected dose produces some foci of degeneration in the renal tubules. Pathologic changes, however, were not observed in mice given the selected oral dose.

Chin attributes the definite tuberculostatic action of lupulon largely to its fat solubility, which enables it to be absorbed by the lipid fraction of the tubercle bacillus. Whether or not lupulon is also tuberculolytic has not been determined.

## RADIATION CATARACTS

As early as 1897[1] physicians knew that roentgen rays could damage some structures of the eye. Unequivocal demonstration of cataract formation in the lens of the irradiated immature kitten was made eight years later.[2] Since that time the entity of radiation cataract has been well established, both clinically and experimentally.[3] Even after the lapse of half a century, the data available are at best qualitative, and many unanswered questions remain as to dosage, species differences and individual variations in biologic susceptibility. Roentgen rays exert their major damage on the dividing cells of the lens equator, and this damage provides the nidus for the slowly developing, progressive lenticular opacities which appear, most characteristically in the posterior subcapsular region.[4]

Recently the development of cataracts in young physicists with a common history of exposure to cyclotron radiations has aroused a new and acute interest in this aspect of radiation injury. Again attention is focussed on the lacunas in our knowledge of the biologic mechanisms involved.[5] In this instance the hazard appears largely attributable to neutrons—particles without electrical charge but with high energy—produced when deuterons (the heavy stable isotope of ordinary hydrogen), accelerated in the magnetic field of the cyclotron, strike the target of the machine.

[5] Cataract in Cyclotron Workers, editorial, New England J. Med. **240:** 441-442 (March 17) 1949.

Until recently, on the basis of acute experiments with mice, the assumption was granted that neutrons were no more than five times as effective as roentgen rays for biologic purposes. Recent work[6] and the sad experience of these young physicists point to the probability that a grave underestimate was made and that for certain organ systems, such as the lens and the gonads, neutrons may have four to eight times the effectiveness originally suspected.

Unfortunately for the physicists, protection procedures and exposure limits were based on the earlier assumption. Once again, as in the past with roentgen rays and radium, people have unwittingly been injured before an adequate understanding of a hazardous agent was had. Furthermore, even now dosimetric methods for neutrons are unsatisfactory.

An understanding of the mechanism of interaction of radiation with the components of biologic matter becomes important. In the case of roentgen rays the energy is first given to electrons, which move at high speed through the tissue. These electrons in turn dissipate their energy by collision with biologic matter, causing chemical alterations. However, the damage to any one cell by one electron is relatively small.

In the case of neutrons the energy is principally dissipated by collision with the hydrogenous component of tissue. The high speed protons thus set in motion liberate a large amount of energy per unit length of path. Thus the passage of one high energy proton through a cell may produce sufficient destruction to injure it permanently.

There is evidence that roentgen rays are relatively effective only against dividing cells, while neutrons may injure the cell at any phase. Thus the biologic effects produced by neutrons may be both quantitatively and qualitatively different from the effects of the roentgen ray. The urgency for research in this relatively unexplored field is evident.

In a broader sense, the experience of these young physicists points to the tremendous responsibility devolving on those—both the physicist-engineers and the agencies supporting their work—who are concerned with exploring the new frontiers of the physical sciences. It is not enough to dismiss the responsibility with the mere warning that a danger may exist or to extrapolate, as was done with the neutron, from inadequate analogies. The biologic implications of the new unknowns should be subjected to investigation parallel with their physical implications and with equal vigor.

## ASBESTOSIS AND CANCER OF THE LUNG

Until recently the coexistence of asbestosis and cancer of the lung was considered by many investigators a coincidence. Since 1935, 23 such cases were recorded by American, English and German physicians. Wedler[1] noted 14 cases of asbestosis cancer in a series of 92 necropsies on patients with asbestosis, or about 15 per cent of cancer of the lung in persons who died from this industrial disease. The exposure time ranged from 3 to 27 years (average 15 years). The ages in 17 cases were 35 to 75 years (average 50 years). Until now the question of a causal relation between asbestosis and cancer of the lung has been an open one. The recently published Annual Report of the Chief Inspector of Factories in England for 1947 provides additional data on the actual existence of such interrelations.[2] During 23 years, 1924 to 1946 inclusive, 235 deaths, either caused by asbestosis or in which asbestosis had been established at necropsy, were reported to the Chief Inspector. Cancer of the lungs or pleura was found in 31 of these cases (13.2 per cent). Of the 128 male deaths in this group 22 (17.2 per cent) were complicated by cancer of the lung, while of the 107 female deaths 9 (8.4 per cent) were similarly affected. The mean age at death from asbestosis complicated by cancer of the lung was 52.1 years. A causal relation between asbestosis and cancer of the lung is supported by the following observations: The incidence rate of cancer of the lung in this group is excessive, since the normal death rate from cancer of the lung among adults examined at necropsy at present is about 1 per cent of all necropsies. Moreover, there is a distinct shift in the sex distribution of cancer of the lung in the series of asbestosis cancers reported from England. The male-female sex ratio is 2.4:1, while it is 5:1 for cancers of the lung in general. This shift indicates that an environmental and evidently occupational carcinogen was active in the asbestosis group, tending to equalize the incidence rate of cancer of the lung for both sexes. Recent experimental observations support this interpretation of clinical evidence. Nordmann and Sorge[3] exposed mice to inhalation of asbestos dust and found that in 20 per cent of the surviving animals there developed squamous cell cancer originating from the bronchial mucosa, while other types of epithelial proliferation were present in 42 to 57 per cent of these animals, in addition to diffuse or nodular fibrosis of the lung. The histologic character of the cancers (squamous cell cancer instead of adenocarcinoma seen in the spontaneous cancer of the lung of mice) and the histogenetic derivation of the tumors (bronchial mucosa instead of alveolar epithelium of the spontaneous type) indicate that a specific factor of exogenous origin, represented by the inhaled asbestos dust, was responsible for the bronchial cancers observed.

[3] Nordmann, M., and Sorge, A.: Lungenkrebs durch Asbeststaub im Tierversuch, Ztschr. f. Krebsforsch. **51**:168, 1941.

Since some 20,000 workers are employed in the asbestos-producing industries of this country and Canada and many additional thousands in various asbestos-consuming industries, increased attention to this probable occupational hazard of cancer of the lung by the medical profession is desirable. Cytologic examinations of the bronchial secretion may well be included in the periodic examination of workers exposed to asbestos dust whenever clinical or roentgenologic evidence indicates the possible existence of a pulmonary cancer. As the available evidence shows that the occurrence of cancer of the lung is related to pulmonary asbestosis and is not merely a possible sequela of exposure to asbestos dust, in all fatal cases of asbestosis there should be postmortem examination with detailed histologic analysis. The anatomic lesions produced by asbestos dust in the lungs make difficult at times distinction by clinical and roentgenologic diagnostic methods between changes of pneumoconiotic nature and those that might indicate a cancerous growth.

## NODULAR PANNICULITIS—WEBER-CHRISTIAN DISEASE

Weber-Christian's disease, or nonsuppurative nodular panniculitis, is characterized by recurring episodes of fever and the development of numerous painful and slightly tender subcutaneous nodules. In only 3 of 33 recorded cases was death apparently due to the disease. In the case reported by Kritzler,[1] in which necropsy was done, the nodular lesions were limited to the subcutaneous fat. However, fat emboli were found in the lungs and there was widespread acute necrosis of the liver and spleen. In the case examined at necropsy by Spain and Foley,[2] necrotic areas were found not only in the subcutaneous fat but in the mesenteric, omental and pretracheal fat. Fat emboli were not found in the lungs, nor were areas of necrosis observed in the liver or spleen. However, foci of fat necrosis were present in the region of the pancreas. A third case investigated at necropsy was that of Mostofi and Engleman,[3] in which nonsuppurative panniculitis involved the skin, the epicardium and the peripancreatic, periadrenal, perirenal and mesenteric tissues. The nodules in the fat are of variable appearance. The earliest lesions consist of small accumulations of fat-laden macrophages. Later, there are somewhat larger lesions that present small areas of central necrosis in the immediate vicinity of which are lymphocytes, polynuclear leukocytes and fat-laden macrophages. In still older nodules, the necrotic material is decreased or absent and the lesions are partially or completely replaced by fibrous tissue. In Spain and Foley's patient, who was an alcohol addict, there were changes indicating a late stage of chronic glomerulonephritis, and death occurred with the symptoms of uremia. Such changes in the kidney are perhaps best interpreted as accidental necropsy findings without direct relationship to the syndrome under discussion. A disease in rabbits apparently analogous to that of nonsuppurative panniculitis in man has been described by Duran-Reynals [4] and others. The cause of Weber-Christian's disease is unknown.

## CRISIS IN SCIENTIFIC RESEARCH

Further evidence that the medical profession must coordinate and intensify its protection of the right to carry on experimental studies on animals in laboratories is provided in a report on this type of legislation in the District of Columbia. Representatives from twenty-six national health and science groups, local hospitals, lay groups and governmental agencies have united behind Senate bill 1703, providing for laboratory use of the 7,000 to 10,000 unclaimed dogs now destroyed each year in the District pound. The usual frenzied distortion and political pressure by antivivisectionists have placed the bill in jeopardy, according to the National Society for Medical Research. The society quotes Dr. A. C. Ivy, its secretary-treasurer, to the effect that members of the special Senate committee to which the bill was referred are personally in favor of it but the bill probably will not be reported out. Dr. Ivy has issued an appeal that interested persons write letters of endorsement to Senator J. Howard McGrath, of Rhode Island, who introduced the measure, and Senator Margaret Chase Smith, of Maine, chairman of the subcommittee. Some such concerted action is necessary at state as well as national levels to beat back efforts of a small, misguided group to obstruct the advancement of science.

## FIRST TELEVISION NETWORK HEALTH SHOW

The first health education program ever presented on a television network was viewed and heard from the NBC-TV studios in Radio City, New York, June 16. Transmitted as far west as Chicago, the program, titled "Your Good Health and the Mighty Atom," was arranged through the Bureau of Health Education of the American Medical Association and produced under the supervision of Mrs. Harriet Hester, radio coordinator for the Bureau. The program dealt with the use of radioisotopes in medicine, particularly radioactive iodine. Dr. Paul C. Aebersold, Chief, Radio-isotopes Division, United States Atomic Energy Commission, Oak Ridge, Tenn., was interviewed by an NBC announcer on the principles of radioactivity. With a Geiger counter specially amplified, Dr. Aebersold demonstrated first how radioactivity can be traced and atoms identified. Later, with a patient furnished by Dr. Sidney C. Werner, Columbia College of Physicians and Surgeons and Presbyterian Hospital, he demonstrated concentration of radioactive iodine in the thyroid.

## Washington Letter

*(From a Special Correspondent)*

Aug. 1, 1949.

### Radioisotope Research Encouraging, Dr. Warren Reports

In the three years that the Atomic Energy Commission has been distributing radioisotopes for medical research, the amount of new knowledge that has been gathered is "amazing," according to Dr. Shields Warren. His observation was made, in his capacity as director of AEC's division of biology and medicine, in the course of a press conference on August 4 on medical-biologic aspects of the Commission's sixth semiannual report submitted to Congress a few days previously.

For particular mention, among projects now being undertaken with AEC financial support, he singled out blood investigations at the University of Michigan and studies of changes in hepatic function in irradiated animals at the Bowman Gray School of Medicine, as well as long range research which has been proceeding in Japan for the last two years under the auspices of the National Research Council.

"Three years ago we assumed that the Commission would have to support a great part of this research," said Dr. Warren. "This has not been necessary. The Commission has found that it has simply to produce the isotopes. The research workers, clinics, laboratories and hospitals need no encouragement to put them to work."

Since August 1946, 7,613 shipments of radioisotopes have been made to research laboratories and hospitals. Nearly 30 per cent of the consignments has been for cancer investigations.

### Medical Missions Leave for Europe and Far East

Departing within twenty-four hours of each other early in August, an Army medical mission left for the Far East on a professional inspection trip and a group headed by Dr. Raymond B. Allen, medical services director of the armed forces, took off from Washington on a ten day tour of military medical installations in Europe.

Members of the Far East party were Col. Warner F. Bowers, chief of the surgical consultants division in the Office of the Army Surgeon General, and three civilian consultants: Dr. Henry H. Kessler (surgery), Newark, N. J.; Dr. Bruce Webster (internal medicine), New York, and Dr. Russell N. DeJong (neuropsychiatry), Ann Arbor, Mich. The tour is scheduled to last thirty-five days.

Dr. Allen was accompanied by the deputy director. Dr. Richard L. Meiling; Charles P. Cooper, chairman of the Armed Forces Medical Advisory Committee; Navy Surgeon General Clifford A. Swanson; Air Force Surgeon General Malcolm C. Grow; Army Deputy Surgeon General George E. Armstrong, and Rear Admiral Joel T. Boone, general inspector of Navy medical activities.

### Telegrams Fifteen to One Against Department of Welfare

The Senate Expenditures Committee had received, up to August 4, approximately 1,500 telegrams and letters protesting the establishment of a Department of Welfare as successor to the Federal Security Agency. It was on August 4 that the Committee, by a 7 to 4 margin, approved the Taft-Fulbright-Hunt resolution disapproving the reorganization plan. Committee officials disclosed that all but 100 of the 1,600 communications received urged approval of the resolution. State, county and local medical societies comprised the majority of the correspondents, while those supporting the Department of Welfare were labor groups and social service organizations in the main. These telegrams and letters were exclusive of the hundreds of similar communications sent to individual members of Congress. Senator Humphrey (D., Minn.) said that he alone received more than 500 of them.

The seven senators who voted against the Department of Welfare plan were John L. McClellan (committee chairman, D., Ark.), James O. Eastland (D., Miss.), A. Willis Robertson (D., Va.), Joseph R. McCarthy (R., Wis.), Irving M. Ives (R., N. Y.), Karl E. Mundt (R., S. D.) and Andrew F. Schoeppel (R., Kansas).

Three Democrats and one Republican constituted the minority: Senators Hubert H. Humphrey (Minn.), Glen H. Taylor (Idaho) and Clyde R. Hoey (N. C.) and the Senate's woman member, Mrs. Margaret Chase Smith (Maine).

### Veterans Administration Issues Hospital Report

As of July 31, 1949, the Veterans Administration was operating 106,491 hospital beds in 130 institutions, according to its latest compilation. Of the total, 48,571 beds were in 99 general medical and surgical hospitals; 48,921 were in 33 mental hospitals and 8,999 were in 18 tuberculosis hospitals. Under construction on that date were 32 hospitals and six additions, comprising a prospective 15,301 beds. In the planning stage were 30 more hospitals and five additions, which would add 21,650 beds.

## Coming Medical Meetings

Aero Medical Association, New York, Aug. 29-Sept. 2. Dr. Thomas H. Sutherland, 214 S. State St., Marion, Ohio, Secretary.

American Association of Obstetricians, Gynecologists and Abdominal Surgeons, Hot Springs, Va., The Homestead, Sept. 8-10. Dr. Leroy A. Calkins, University of Kansas Medical Center, Kansas City 3, Kan., Secretary.

American Congress of Physical Medicine, Cincinnati, Netherlands Plaza Hotel, Sept. 6-10. Dr. Richard Kovacs, 2 E. 88th St., New York 28, Secretary.

American Hospital Association, Cleveland, Sept. 26-29. Mr. George P. Bugbee, 18 East Division St., Chicago, Executive Secretary.

American Roentgen Ray Society, Cincinnati, Oct. 4-7. Dr. H. Dabney Kerr, University Hospitals, Iowa City, Iowa, Secretary.

Colorado State Medical Society, Denver, Shirley-Savoy Hotel, Sept. 20-23. Mr. Harvey T. Sethman, 835 Republic Bldg., Denver, Executive Secretary.

Gulf Coast Clinical Society, Pensacola, Fla., Oct. 6-7. Dr. Arthur J. Butt Jr., Pensacola, Fla., Secretary.

Indiana State Medical Association, French Lick, Sept. 25-27. Mr. Ray E. Smith, 1021 Hume-Mansur Bldg., Indianapolis 4, Executive Secretary.

International Congress of Biochemistry, Cambridge, England, Aug. 19-25. Lieut. Col. Francis J. Griffin, 56 Victoria St., London, W.C.1, Organizer.

International Neurological Congress, Paris, France, Sept. 5-10. Dr. Raymond Garcin, 19 rue de Borgogne, Paris, General Secretary.

Kansas City Southwest Clinical Society, Kansas City, Mo., Municipal Auditorium, Oct. 3-6. Dr. W. Merritt Ketcham, 630 Shukert Bldg., Kansas City, Mo., Secretary.

Kentucky State Medical Association, Owensboro, Oct. 6-9. Dr. Bruce Underwood, 620 S. Third St., Louisville 2, Secretary.

Michigan State Medical Society, Grand Rapids, Pantlind Hotel and Civic Auditorium, Sept. 21-23. Dr. L. Fernald Foster, 2020 Olds Tower, Lansing 8, Secretary.

Mississippi Valley Medical Society, St. Louis, Jefferson Hotel, Sept. 28-30. Dr. Harold Swanberg, 209-224 W. C. U. Bldg., Quincy, Ill., Secretary.

Nevada State Medical Association, Elko, Sept. 29-Oct. 1. Dr. Roland W. Stahr, 118 California Ave., Reno, Secretary.

Northern Minnesota Medical Association, Alexandria, Sept. 9-10. Dr. C. L. Oppegaard, Crookston, Secretary.

Pennsylvania, Medical Society of the State of, Pittsburgh, Hotel William Penn, Sept. 26-29. Dr. W. F. Donaldson, 8104 Jenkins Arcade, Pittsburgh 22, Secretary.

Southern Minnesota Medical Association, Red Wing, Sept. 12, Dr. W. A. Merritt, Rochester, Secretary.

Southwestern Surgical Congress, Houston, Tex., Shamrock Hotel, Sept. 26-28. Dr. C. R. Rountree, 525 N.W. Eleventh St., Oklahoma City 3, Secretary.

Utah State Medical Association, Salt Lake City, Sept. 1-3. Dr. Ray T. Woolsey, 42 S. Fifth East St., Salt Lake City 2, Secretary.

Vermont State Medical Society, Burlington, Sept. 8-9. Dr. James P. Hammond, 542 Main St., Bennington, Secretary.

Washington State Medical Association, Seattle, Olympic Hotel, Sept. 11-14. Dr. James W. Haviland, 338 White-Henry-Stuart Bldg., Seattle, Secretary.

Wisconsin, State Medical Society of, Milwaukee, Hotel Shroeder and Milwaukee Auditorium, Oct. 3-5. Mr. Charles H. Crownhart, 704 E. Gorham St., Madison, Secretary.

Wyoming State Medical Society, Casper, Sept. 12-14. Dr. George H. Phelps, 1606 Capitol Avenue, Cheyenne, Secretary.

# GOVERNMENT SERVICES

## ARMY

### ACCEPTED FOR ADVANCED TRAINING

The following medical officers have been accepted for advanced training by the civilian institutions indicated:

Col. Joseph F. Peters, Lieut. Col. Merrill C. Davenport and Lieut. Col. Frederick J. Hughes, American Trudeau Society, New York, Diseases of the Chest.

Lieut. Col. Marco B. Bonsignore, Washington University, St. Louis, Orthopedic Surgery.

Lieut. Col. Douglas B. Kendrick, Mayo Foundation, Rochester, Minn., Surgery.

Major John L. Bradley, Georgetown University, Washington, D. C., *Internal Medicine.*

Capt. Stuart H. Walker, Western Reserve University, Cleveland, Pediatrics.

First Lieut. Thelma Kiltz, St. Mary's Infirmary, Galveston, Texas, Anesthesiology.

First Lieut. Gracieuse L. Muirhead, St. Mary's Infirmary, Galveston, Texas, Anesthesiology.

First Lieut. H. A. Blake, Cornell University Medical College, New York, Surgical Anatomy.

Col. Joseph F. Peters, University of Colorado, Denver, Regional Anesthesia.

Lieut. Col. James H. Fairchild, University of California, San Francisco, Prosthesis.

Lieut. Col. Franklin S. Blanton, Cornell University, Ithaca, N. Y., Entomology.

Major Samuel P. Daykin, Washington University, St. Louis, Psychiatric Social Work.

Major Trygve O. Berge, University of California, Berkeley, Calif., Bacteriology and Virology.

Capt. Ralph W. Morgan, Indiana University, Bloomington, Ind., Psychiatric Social Work.

Capt. Lee B. Grant, University of Cincinnati, Cincinnati, Internal Medicine.

Capt. Euclid G. Herndon Jr., Cleveland Clinic Foundation Hospital, Cleveland, Research Medicine.

Capt. Thomas J. Whelan Jr., Strong Memorial Hospital, Rochester, N. Y., Surgery.

Capt. Thomas S. Martin, Passavant Memorial Hospital, Chicago, Internal Medicine.

Capt. Robert F. Wright, Boston City Hospital, Boston, Otolaryngology.

Capt. Stephen J. Berte, St. Vincent's Hospital, New York, Medicine.

Capt. John K. Spitznagel, Barnes Hospital, St. Louis, Internal Medicine.

Capt. Clem C. Crossland Jr., George Washington University Hospital, Washington, D. C., Pathology.

Capt. Allan C. Evans, Parkland Hospital, Dallas, Texas, Obstetrics and Gynecology.

Capt. Frank E. Schwartz, Eye and Ear Hospital, Pittsburgh, Ophthalmology.

First Lieut. Frank L. Dunn, and First Lieut. George A. Colom, Colorado Psychopathic Hospital, Denver, Psychiatry.

First Lieut. Edward L. Buescher, Children's Hospital, Cincinnati, Virology.

First Lieut. Joseph L. Giradeau, Grady Memorial Hospital, Atlanta, Ga., Obstetrics and Gynecology.

First Lieut. James D. Roorda, St. Elizabeth's Hospital, Chicago, and Alexian Brothers' Hospital, Chicago, Internal Medicine.

First Lieut. John N. Gordon, Medical College of Virginia, Richmond, Obstetrics.

First Lieut. John A. Moncrief, Barnes Hospital, St. Louis, Surgery.

First Lieut. Thomas H. Moseley, Crawford W. Long Hospital, Atlanta, Ga., Obstetrics and Gynecology.

First Lieut. William G. Phippen, Syracuse University Medical Center, Syracuse, N. Y., Surgery.

First Lieut. Gilbert A. Varnell, Baroness Erlanger Hospital, Chattanooga, Tenn., Obstetrics.

First Lieut. Robert C. Gildersleeve, White Memorial Hospital, Los Angeles, Fellowship in Oncologic Surgery.

First Lieut. John Q. Thompson, Henry Ford Hospital, Detroit, Medicine.

First Lieut. Archibald M. Ahern, St. Mary's Hospitals, St. Louis, Internal Medicine.

First Lieut. Thomas P. Clarke, Colorado Psychopathic Hospital, Denver, Psychiatry.

First Lieut. Robert R. Hahn, University Hospital, Baltimore, Medicine.

First Lieut. John B. Selby, Garfield Hospital, Washington, D. C., Medicine.

First Lieut. Jack E. Geist, Minneapolis General Hospital, Minneapolis, Neuropsychiatry.

First Lieut. John C. Baber Jr., Missouri Pacific Hospital, St. Louis, and St. Lukes Hospital, St. Louis, Surgery.

First Lieut. Robert C. Gardner, St. Louis Children's Hospital, St. Louis, Pediatrics.

First Lieut. Richard K. Cole Jr., University of Virginia Hospital, Charlottesville, Va., Psychiatry.

First Lieut. David W. Wardell, Colorado State Hospital, Pueblo, Colo., Psychiatry.

First Lieut. Louis J. West, New York Hospital, New York, Psychiatry.

First Lieut. William F. Creeps, University of California Hospital, San Francisco, Obstetrics and Gynecology.

First Lieut. Gerald A. Champlin, Missouri Baptist Hospital, St. Louis, Surgery.

First Lieut. Charles C. Parker, Medical College of Virginia, Richmond, Surgery.

First Lieut. Vol K. Phillips, New York Hospital, New York, Internal Medicine.

First Lieut. Donald G. Pocock, Cleveland City Hospital, Cleveland, Internal Medicine.

First Lieut. William H. Weingarten, Northwestern Hospital, Minneapolis, Surgery.

First Lieut. Richard K. Blaisdell, Charity Hospital of Louisiana, New Orleans, Medicine.

First Lieut. Anthony L. Brittis, Bellevue Hospital, New York, Physical Medicine.

First Lieut. Joseph V. Conroy Jr., Medical Center, Jersey City, N. J., Surgery.

First Lieut. Clifford P. Coplerud, Grady Memorial Hospital, Atlanta, Ga., Obstetrics and Gynecology.

First Lieut. Ira B. Harrison, Emory University Hospital, Atlanta, Ga., Internal Medicine.

First Lieut. Robert H. Moser, Georgetown University Hospital, Washington, D. C., Internal Medicine.

First Lieut. Paul E. Teschan, Presbyterian Hospital, Chicago, Internal *Medicine.*

First Lieut. Charles E. Butterworth, Jefferson-Hillman Hospital, Birmingham, Ala., Internal Medicine.

First Lieut. William J. Dean and First Lieut. Armand E. Hendee, Grady Memorial Hospital, Atlanta, Ga., Internal Medicine and Obstetrics and Gynecology, respectively.

First Lieut. John B. Logan, Garfield Memorial Hospital, Washington, D. C., Internal Medicine.

First Lieut. Roscoe E. Mason, Boston City Hospital, Boston, Surgery.

First Lieut. Carter L. Meadows, Emory University Hospital, Atlanta, Ga., Surgery.

First Lieut. Francis J. Peisel, Morrisania City Hospital, Bronx, N. Y., Otolaryngology.

First Lieut. Robert H. Wildhack, Millard Fillmore Hospital, Buffalo, Obstetrics and Gynecology.

First Lieut. Don G. Bock, Methodist Hospital, Indianapolis, Internal Medicine.

First Lieut. William W. Bindeman, West Baltimore General Hospital, Baltimore, Surgery.

First Lieut. Robert M. Senty, Charles T. Miller Hospital, St. Paul, Internal Medicine.

First Lieut. Robert M. Counts, Barnes Hospital, St. Louis, Neuropsychiatry.

First Lieut. Samuel L. Dunaif, Bellevue Hospital, New York and New York State Psychiatric Institute, New York, Psychiatry.

First Lieut. Williford Eppes, University Hospital, Baltimore, and State University of Iowa Hospitals, Iowa City, Medicine.

First Lieut. David A. Hamburg, Yale University, New Haven Hospital, New Haven, Conn., Psychiatry, and Michael Reese Hospital, Chicago, Neuropsychiatry.

First Lieut. John H. Webb Jr., Grady Memorial Hospital, Atlanta, Ga., Surgery.

Lieut. Col. Warren J. Barker, University of Chicago School of Medicine, Chicago, Psychiatry, and Institute for Psychoanalysis, Chicago, Personal Psychoanalysis.

Major Hinton J. Baker, Mary Imogene Bassett Hospital, Cooperstown, N. Y., Tissue Culture.

### PERSONAL

Colonel Emmett M. Smith has been appointed chief of the Physical Medicine Consultants Division in the Surgeon General's office and Colonel Hugh R. Gilmore Jr., head of the Pathology and Allied Sciences Division.

Dr. Lewis H. Weed, chairman of the Surgeon General's Committee on Medical Indexing, Army Medical Library, has resigned on account of illness.

## NAVY

### MONTHLY MEDICAL MEETING

Dr. Richard B. Cattell, of Boston, was the guest speaker at the Naval Medical School, Bethesda, Md., June 2, 1949. Dr. Cattell lectured on "Management of Inflammatory Lesions of the Small and Large Intestines."

### PERSONAL

Lieutenant Wendell W. Robley, MC, has been recently certified by the American Board of Radiology.

### DUTY UNDER INSTRUCTION

The following officers have been nominated for duty under instruction in the Graduate Medical Training Program:

Comdr. Benjamin W. Clark, General Surgery, University of Pennsylvania Graduate School of Medicine.

Comdr. Paul R. Engle, Tropical and Internal Medicine, Tulane University School of Medicine.

Comdr. James E. Eppley, Surgery, University of Pennsylvania Graduate School of Medicine.

Comdr. Donald W. Miller, Surgery, Naval Hospital, San Diego.

Comdr. Derrick C. Turnipseed, Surgery, Naval Hospital, Long Beach, Calif.

Comdr. John D. Walters, Dermatology and Syphilology, Naval Hospital, Philadelphia.

Comdr. Elwood L. Woolsey, Obstetrics and Gynecology, University of Pennsylvania Graduate School of Medicine.

Lieut. Comdr. Wm. G. Lawson, Dermatology and Syphilology, Naval Hospital, San Diego.

Lieut. (jg) William T. Lineberry, Surgery, University of Pennsylvania Graduate School of Medicine.

Lieut (jg) Edward J. Rupnik, Surgery, Naval Hospital, National Naval Medical Center, Bethesda, Md.

Lieut. (jg) Alan D. Watson, Dermatology and Syphilology, Skin and Cancer Unit, New York University College of Medicine.

Lieut. (jg) Sydnor T. Withers, Dermatology and Syphilology, Naval Hospital, St. Albans, N. Y.

Lieut. (jg) Henry E. Wolfe Jr., Urology, James Buchanan Brady Foundation of New York Hospital.

# VETERANS ADMINISTRATION

## MATHEMATICAL FORMULA FOR SELECTING HOSPITAL SITES

Carl R. Gray Jr., Veterans Administrator, announces that Salisbury, N. C., was chosen as the site for a 1,000 bed neuropsychiatric hospital which is expected to cost about $17,000,000. The Veterans Administration has owned the land, 411 acres, since 1945. Mr. Gray inspected several sites in North Carolina before selecting the one at Salisbury, and after he returned to Washington a mathematical formula was devised by which sites could be compared with each element of importance in locating a hospital, so that the selection could be made strictly on a mathematic basis. This formula proved so successful in this instance, Administrator Gray announced that it will be used in all future selections of hospital sites. The Salisbury site chosen, he said, is not quite as good as some others from the point of view of the association with medical schools; but the fact that the city of Salisbury has spent $304,000 and the U. S. Government has spent $1,030,000 on the site more than outweighed this consideration, and it was determined to use the site which was originally selected for a hospital and abandoned when the Veterans Administration construction program was cut back earlier this year.

Before the Administrator announced his decision, the chief medical director (Dr. Paul B. Magnuson) and assistant administrators concerned in locating hospitals, were consulted and all participated in the application of the formula to this particular selection. They were unanimous in their agreement on the selection and the use of the formula for future hospital sites.

## NEW HOSPITAL MANAGERS

The Veterans Administration announces the following appointments: Dr. John F. Bresnahan to be manager of the hospital at Fayetteville, Ark., replacing Dr. Frank N. Gordon, who retired on account of age; Dr. Louis V. J. Lopez to be manager of the hospital at Fort Meade, S. D., succeeding Dr. Harold E. Foster, who died April 19; Dr. George S. Littell to succeed Dr. Bresnahan, who formerly was manager of the Wichita hospital, Kansas.

## PERSONAL

Dr. John W. Claiborne became manager of the Veterans Hospital at Jefferson Barracks, Mo., July 24, replacing Dr. Walter A. German, who became chief medical officer in the Veterans Administration Regional Office at Miami, Fla.

Roger J. O. Cumming, formerly of Minneapolis, has been appointed chief of the Veterans Administration social service division, effective August 29. Mr. Cumming obtained his master's degree from the University of Chicago's School of Social Service Administration. He served in the Navy during World War II.

Dr. Hayden H. Donahue has resigned from the staff of the Fort Roots Veterans Hospital, Arkansas, and has become director of research and education at the Arkansas State Hospital for Mental Diseases. He also is an associate professor of neuropsychiatry at the University of Arkansas School of Medicine.

Dr. Francis A. Bulawa of Charles City, Iowa, has joined the orthopedic staff of the veterans hospital at St. Petersburg, Fla. Dr. Bulawa served in the Navy in the Pacific during the recent war.

Dr. Michael Matte is now the chief medical officer at the veterans' hospital at Wood, Wis. Before this assignment he was chief of the hospital section of the medical division in the central office of the Veterans Administration in Washington, D. C.

Dr. David B. Witt became chief medical officer of the Veterans Administration office at Champaign, Ill., August 8.

# SECRETARY OF DEFENSE

## DRS. ALLEN AND MEILING TAKE OATHS AS DIVISION CHIEFS

Drs. Raymond B. Allen and Richard L. Meiling were sworn in July 6 by Secretary of Defense Louis Johnson as Director and Deputy Director, respectively, of the newly formed Medical Services Division of the National Military Establishment. Dr. Allen, who is President of the University of Washington, Seattle, will remain as Director of Medical Services for three months, returning to the University of Washington on October 1. At that time Dr. Meiling, who is on the staff of the College of Medicine of Ohio State University, Columbus, will be appointed Director. The ceremony in Secretary Johnson's office was witnessed by top officials of the National Military Establishment and other government agencies.

## SIXTY-THREE MORE BOARDS AND COMMITTEES ABOLISHED

Secretary of Defense Louis Johnson announced July 21 the abolition of 63 more boards and committees in the National Military Establishment. The groups were found either to have completed the work for which they were established or to be duplicating the functions of other organizations. Among the groups thus abolished were: (1) the Board to Study the U. S. Navy Band, (2) the Air Force Human Resources Board, (3) the Committee on Implementation of the Randolph Health Act and Foreign Service Act of 1946 and (4) the Army Information Committee. The total of committees and boards discontinued since April 1, 1949 is now 133.

# PUBLIC HEALTH SERVICE

## INSPECTION TRIP TO PUERTO RICO

Dr. Raymond B. Allen, director, Medical Services Division, National Military Establishment, arrived in San Juan, Puerto Rico, July 17, with an inspection party of military medical officers, including Dr. Richard L. Meiling, deputy director, the Surgeons General of the Army and Navy and Air Corps and Rear Admiral Joel T. Boone of the U. S. Navy. They visited the Naval Station Dispensary at San Juan, Rodriguez General Hospital, the Veterans Administration Hospital (San Patricio) and the Army Medical Laboratory. They were entertained by Admiral D. E. Barbey and General Sibert. Among the guests were: Dr. Dwight S. Stevenson, director of the Presbyterian Hospital; Dr. Davis J. Zaugg, director of U. S. Public Health Service; Dr. Guillermo Arbona, commissioner of health; Dr. Enrique Koppisch, acting director of the School of Tropical Medicine, and Dr. Jaime Serra Chavarry, manager, Veterans Administration of Puerto Rico.

# Medical News

**(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)**

## ARKANSAS

**Dr. Wells Heads Department.**—Dr. Benjamin B. Wells, director of cancer research at the M. D. Anderson Hospital for Cancer Research, Houston, Texas, assumed his duties July 1 as head of the department of internal medicine at the University of Arkansas School of Medicine, Little Rock. Dr. Wells, a graduate of Baylor University College of Medicine, Houston, 1935, served on the faculty of the University of Arkansas from 1946 to 1948 as professor of medicine and also as dean the last year.

## CALIFORNIA

**St. John's Hospital Fall Clinic.**—St. John's Hospital, Santa Monica, will present its first Annual Fall Clinic September 12-14. The program includes symposiums on hyperthyroidism, the genitourinary system and jaundice; seminars in obstetrics and gynecology, pediatrics and hematology; a clinical pathologic conference, and peripheral-vascular clinic. Out of state guest speakers include Drs. Percy J. Carroll, Harry H. McCarthy and Louis D. McGuire, Omaha, Neb.; Malcolm B. Dockerty, Rochester, Minn., and Cyrus C. Sturgis, Ann Arbor, Mich. All interested physicians are invited to attend.

**Grants for Cardiovascular Research.**—Grants totaling $11,820 to six Los Angeles County researchers for work in cardiovascular disease have been announced by the Los Angeles Heart Association, the Los Angeles County Tuberculosis and *Health Association, and the A. M. Roberts Memorial Fund,* administered by the Heart Division of the tuberculosis association. The research workers are: Dr. Thomas H. Brem, Veterans Hospital, Van Nuys; Dr. Harry Goldblatt, director of the Cedars of Lebanon Hospital Institute for Medical Research, Los Angeles; Drs. George C. Griffith, Helen E. Martin and Douglas R. Drury, University of Southern California Medical School, Los Angeles, and Dr. Travis Winsor, medical director, Nash Foundation, Hospital of the Good Samaritan, Los Angeles.

## INDIANA

**Governor Appoints Tuberculosis Council.**—A seven member Indiana Tuberculosis Council to aid the Indiana State Board of Health in the treatment and care of tuberculosis was recently appointed by Governor Henry F. Schricker. The council was established by the 1949 General Assembly. Physician appointees are: Dr. Warren S. Tucker, Indianapolis, one year; Dr. Thomas R. Owens, Muncie, one year, and Dr. John R. Matthews, North Judson, two years. Laymen include Murray A. Auerbach, Indianapolis, executive secretary, two years; Robert O'Bannon, Corydon, four years, and Custis Hostetter, Lafayette, four years.

**Personals.**—Dr. A. David McKinley, who practiced medicine in Speedway before entering service in World War II, has been appointed assistant medical director for the Indiana University Medical Center Hospitals in Indianapolis. Dr. McKinley received his M.D. degree from Indiana University School of Medicine, Indianapolis, in 1939.——Dr. Earl W. Mericle, Indianapolis, has been appointed by Gov. Henry F. Schricker to the Indiana Council for Mental Health to succeed Dr. E. Rogers Smith, also of Indianapolis, who resigned.——James A. Waggener, public relations director for the Indiana Blue Cross-Blue Shield organizations for two years, has become field secretary of the Indiana State Medical Association.

## KANSAS

**Dr. Sutton Heads Department of Dermatology.**—Dr. Richard L. Sutton Jr., Kansas City, became chairman of the department of dermatology at the University of Kansas School of Medicine, Lawrence-Kansas City, July 1, succeeding Dr. Charles C. Dennie, who has reached the retirement age for university executives. A graduate of the University of Michigan Medical School, Ann Arbor, 1929, Dr. Sutton was an associate professor of dermatology at the University of Kansas School of Medicine from 1943 to 1946. He was a major in the medical corp of the U. S. Army and chief of the skin and syphilis section of the Woodrow Wilson General Hospital, Staunton, Va. He is on the staffs of the Ellis Fischel State Cancer Hospital and the University Hospital in Columbia, and Kansas City General, Menorah, and St. Lukes hospitals in Kansas City. Dr. Dennie has been a member of the faculty for 32 years and chairman of the department for 10 years.

## MAINE

**State Medical Election.**—The Maine Medical Association at its meeting in Poland Springs in June installed Dr. Ralph A. Goodwin of Auburn as president and chose Dr. Foster C. Small, Belfast, president-elect.

**Reorganize Administration of Jackson Laboratory.**—As a part of plans for broad reorganization and extension of the staff of the Jackson Memorial Laboratory in Bar Harbor, George Davis Snell has been appointed scientific administrator. He will work with another executive under the director, Clarence C. Little, Sc.D. Dr. Snell received his Sc.D. degree from Harvard University in 1930 and since 1935 has been a research associate, a member of the staff and, in recent years, a trustee of the laboratory, as well as chairman of a number of important committees.

## MASSACHUSETTS

**Warren Triennial Prize.**—The Warren Triennial Prize for the best dissertation on some special subject in physiology, surgery or pathology will be awarded this year. Essays may be written in English, French or German and must be typewritten and suitably bound. Work that has previously been published will not be considered, and original work will be given a high value. Essays will be received until November 15. The awards will consist of a first prize of $1,500 and a second prize of $500. The judges will be the General Executive Committee of the Massachusetts General Hospital, Boston.

**Psychiatric Study Grant.**—The U. S. Public Health Service under the National Mental Health Act has approved a grant for a trainee in psychiatry at the Walter E. Fernald State *School situated 8 miles from Boston. The stipend for this level* is $3,000 per year, but candidates at lower levels may be considered. Training will be offered in mental deficiency, child psychiatry and related psychiatric and neurologic problems through supervised experience in the outpatient, inpatient, research laboratory, psychologic, education and social service departments, as well as participation in staff meetings, seminars in basic psychiatry and neurology and in child psychiatry. Applications or requests for further information should be forwarded to Dr. Malcolm J. Farrell, Superintendent, Walter E. Fernald State School, Waverley 78.

## MISSOURI

**County Health Forum Lectures.**—The Jackson County Health Forum Lecture Series, sponsored by the hospital auxiliaries of the accredited hospitals of Jackson County, will begin September 21 and continue each month, except December, through April. These public lectures are held at 8:15 p. m. at the Little Theatre of the Municipal Auditorium in Kansas City and are free of charge. The program is as follows:

Sept. 21, Howard B. Sprague, Boston, Heart and Circulation.
Oct. 19, Austin Smith, Assistant Editor, THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, Chicago, Modern Miracles in Drugs.
Nov. 23, Lawrence T. Post, St. Louis, Your Sight and Your Glasses.
Jan. 18, William P. Holbrook, Tucson, Ariz., Arthritis and Rheumatism.
Feb. 15, George H. Mohr, Chicago, Everybody's Problem.
March 15, Walter C. Alvarez, Rochester, Minn., Nervous Indigestion.
April 19, Morris Fishbein, Editor, THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, Chronic Diseases and the Aged.

## NEW YORK

**Honor Veteran Physicians.**—The Medical Society of the County of Niagara on June 14 honored county physicians who had practiced medicine for more than 50 years. Those cited were Dr. William H. Hodge, Niagara Falls, who has practiced 60 years in the county; Dr. Heinrich C. Leonhardt, North Tonawanda, 59 years; Dr. William G. Sprague of Barker and Dr. Thomas J. McBlain, Lewiston, 58 years each; Dr. Murray Mudge, Middleport, 54 years; Drs. Norman W. Price, Niagara Falls, and Carl A. Blackley, Lockport, 53 years each; Drs. Lyman H. Wheeler, Lockport, Clayton R. Clarke, Ransomville, and Henry C. Lapp, North Tonawanda, 52 years each; and Dr. E. Herbert Purvis, Lockport, 50 years. Also honored were Dr. Elbert A. Palmer, Niagara Falls, who has practiced medicine in the county and elsewhere for 53 years and Dr. Samuel Outwater, Lockport, who has practiced 70 years in Buffalo and in California.

## New York City

**Society of Medical Jurisprudence.**—Twenty-two representatives of the medical and legal professions on June 1 organized the Brooklyn Society of Medical Jurisprudence under the leadership of Dr. George I. Swetlow, Brooklyn. The active membership will be composed of the active members of the medical, legal and dental professions.

**Dr. Lough Honored.**—After 37 years of teaching and medical practice Dr. Walter G. Lough will retire August 31 from his duties as professor and chairman of the department of medicine, New York University Post-Graduate Medical School, and director of the medical service, University Hospital. A testimonial dinner in his honor was given at the Waldorf-Astoria Hotel, June 21.

**Seton Hospital Affiliates with Medical College.**—A teaching affiliation in the specialty of pulmonary diseases has been arranged between Seton Hospital and the New York Medical College, Flower and Fifth Avenue Hospitals. As soon as practicable graduate training will be undertaken, and in the future undergraduate instruction may also be instituted. The affiliation will provide a source of residents for the hospital and offers another institution to the college for specialized training in the field of pulmonary diseases. The 429 bed tuberculosis institution was taken over by the city May 1, 1949. Dr. Allen Kane is the medical superintendent.

**Faculty Changes at Long Island College.**—The following changes in the faculty of the Long Island College of Medicine have been announced: Dr. Charles A. Gordon, a member of the faculty since 1923, has been named emeritus professor of obstetrics and gynecology, and Dr. Carl H. Laws, associated with the college since 1917, has been made a professor emeritus of pediatrics. Retiring by reason of mandatory age requirements are Dr. Milton G. Wasch, associate professor of clinical radiology and attending resident at the Jewish Hospital of Brooklyn since 1916, where he conducted his teaching duties; and Dr. Harry W. Mayes, a member of the department of obstetrics and gynecology for a number of years, conducting his teaching assignments at the Methodist Hospital of Brooklyn.

**Public Health Research Institute.**—The city of New York has signed a seventeen year extension of its contract with the Public Health Research Institute whereby the city will grant to the institute $300,000 annually for two years and $400,000 annually for the remaining fifteen years of the contract. Chartered in 1941, the institute since 1945 has been receiving $200,000 each year from the city for a cooperative medical research program. The Public Health Research Institute is a nonprofit membership corporation, the research activities of which are under the direction of a council of scientists; Dr. Thomas M. Rivers, director, Hospital of the Rockefeller Institute for Medical Research, is the chairman. Dr. Walter W. Palmer, professor emeritus, Columbia University College of Physicians and Surgeons, is director of the institute. The institute already has served the city by improved methods of measuring nutrition, better means of preserving blood for transfusion, evaluation of dangers in continuous and indiscriminate use of sulfonamide drugs, better immunization technics and development of a virus diagnostic laboratory.

## TEXAS

**Open Medicolegal Laboratory.**—A medicolegal laboratory, operated under a cooperative arrangement of the county, the University of Texas and the M. D. Anderson Foundation, was established recently in Houston. Located in the basement of Jefferson Davis Hospital, the laboratory is headed by Dr. W. W. Coulter Sr., chief pathologist at the hospital, with Dr. Charles A. Dwyer Jr., county physician, as his assistant. The laboratory, which will be used in teaching medicolegal pathology in the University of Texas Postgraduate School of Medicine, is under the general direction of Dr. William O. Russell, head of the department of pathology of the University of Texas Medical Branch, Galveston.

**Dr. Livingood to Head Department.**—Dr. Clarence S. Livingood, assistant professor of dermatology and syphilogy and head of the department at Jefferson Medical College, Philadelphia, has been named professor of dermatology and syphilology at the University of Texas Medical Branch, Galveston. Dr. Livingood, a graduate of the University of Pennsylvania, Philadelphia, 1936, is also an assistant professor in his field at the Graduate Medical School of the University of Pennsylvania in Philadelphia. Other appointments to the faculty include that of Dr. Elwood E. Baird, professor of clinical pathology at the University of Colorado School of Medicine, Denver, as professor of clinical pathology in charge of the clinical laboratories at the University of Texas Medical Branch Hospital.

## PUERTO RICO

**Hospital Construction.**—A master plan for the construction of three hospitals in Southern Puerto Rico, preferably in the city of Ponce, has been prepared by the Hospital Survey and Construction Agency, a division of the Insular Health Department, in cooperation with the U. S. Public Health Service. Preliminary plans are now under way for the construction with federal and insular funds of a 500 bed tuberculosis hospital, a 1,000 bed mental hospital and a 400 bed general hospital. These three hospitals will be constructed as soon as an amendment to the Hospital Survey and Construction Act of 1946 is approved by the United States Congress, extending the life of this legislation to 1955 and increasing the allocation of federal funds to twice the present appropriations. The law provides an allocation of $2,400,000 for the fiscal year 1948-1949, already received by Puerto Rico, and a similar amount for the fiscal year 1949-1950 for investment in an islandwide hospital construction and improvement program. Out of these funds, according to insular health officials, Puerto Rico will construct before 1951 the Ponce General District Hospital, costing $3,000,000. It will have a chronic disease section for the treatment of cancer and renal and heart diseases. The federal government pays one third of the cost of these units, and the balance is paid with insular funds.

Julio A. Pérez, director of the Office of Puerto Rico in Washington, D. C., who until recently was executive secretary of the Hospital Survey and Construction Agency, has been inspecting hospitals in the United States to obtain reliable information of surgical treatment and installations for chest disease operations that will be purchased for the Ponce tuberculosis hospital.

If the amendment to the Hospital Survey and Construction Act now under consideration in Congress is finally approved, a sliding scale of funds will be provided through which the federal government will match up to two thirds of the cost of several projects. A master plan for the construction of all hospital units in Puerto Rico has been approved by the Puerto Rico planning board on the basis of the actual legislation. This means that, with additional federal funds to match insular funds, the plan will be enlarged accordingly.

## GENERAL

**Change Journal's Editorial Office.**—At the June 1949 meeting of the Society for Investigative Dermatology, Dr. Naomi M. Kanof, Washington, D. C., was appointed chairman of the editorial board and Dr. Marion Sulzberger, New York, was named chief editorial consultant. Manuscripts and inquiries should be addressed to the editorial office of the *Journal of Investigative Dermatology* at 1150 Connecticut Avenue N.W., Washington 6, D. C.

**International Congress on Cancer.**—The fifth International Congress for Scientific Research and the Social Fight Against Cancer is to be held at the Sorbonne in Paris July 17-22, 1950. Dr. A. Lacasagne is president of the congress. Participation is open to members of well known scientific and social associations or to men recommended by members of the executive committees as well as the organizations affiliated with the union. Correspondence can be directed to Prof. V. LeLorier, Secretary-General of the Congress, 6 Avenue Marceau, Paris 8, France.

**International Congress of Military Medicine.** — The Twelfth International Congress of Military Medicine and Pharmacy will be held in México, D. F., October 23-29. Topics under discussion include new medicosocial problems in the army; pathology and treatment of lesions caused by the atomic bomb; the psychoses of war and the biochemical study of the minimum ration of the combat soldier; maxillofacial wounds; air transport for the medical services to the combat forces, and the study of medicaments. This congress will be followed, on November 6-8, by the twelfth session of the Conference of the International Office of Documentation of Military Medicine in Havana. The association on November 7 will take up the subjects: reparative surgery of maxillofacial wounds, project of codification of international medical law and the outlook for medicine in times of war. The International Committee of Military Medicine and Pharmacy will also meet.

**"Uniform Salesman" Racket.**—A man calling himself H. D. Hunter and representing himself as a salesman for the Hoover Manufacturing Sales Company, 251 West 19th Street, New York 11, has been accepting orders and cash deposits for nurses' uniforms in Greenville, S. C. This man is not a legal representative and is not connected with this company. He has been apprehended previously and tried and convicted fo *obtaining money under false pretenses by working this same* racket. H. D. Hunter is described as being between 45 and 50 years of age, 5 feet 6 inches tall and approximately 170 pounds in weight. He has brownish black hair, graying at the temples. He wears tortoise-shell-rimmed glasses and appears to be Jewish. He is courteous and gentlemanly in manner and dresses neatly in business suits. He has a catalog and samples of the Hoover Manufacturing Sales Co. and will accept a check in payment for orders but insists that the check be made payable to him. Any information concerning this man should be addressed to Detectives L. G. Dill and C. E. Howard, Department of Police, Greenville, S. C.

**Markle Scholars in Medical Science Nominations.**—The John and Mary R. Markle Foundation invites deans of accredited medical schools in the United States and Canada to make nominations for the third group of scholars in medical science on or before Dec. 1, 1949. Each school may nominate one candidate. The purpose of the scholar program is to help promising young men and women with a strong interest in teaching and research to become established in academic medicine. Candidates should have completed the usual fellowship training in some area of science related to medicine and should hold, or expect to hold, in the academic year 1950-1951 a full time faculty appointment on the staff of a medical school. Grants of $250,000, payable at the rate of $5,000 annually, will be made to the schools over a five year period for the support of each scholar finally selected, his research, or both. The number of scholars to be appointed in 1950 has not yet been determined. Sixteen were chosen in 1948 and thirteen in 1949. A new booklet describing the plan, with suggestions for making application, is available on request from the Foundation, 14 Wall Street, New York 5, N. Y.

**Obstetricians, Gynecologists and Abdominal Surgeons Meeting.**—The annual meeting of the American Association of Obstetricians, Gynecologists and Abdominal Surgeons will be held at the Homestead, Hot Springs, Va., September 8-10, under the presidency of Dr. James R. Bloss, Huntington, W. Va. Physicians invited to deliver papers at the scientific sessions include:

Douglas W. Sparling, Montreal, Que., Theca Cell Tumors.
Edward C. Hughes, Syracuse, N. Y., Nutritional Value of the Endometrium for Implantation and Habitual Abortion.
Kenneth T. MacFarlane, Montreal, Que., Uterine Sarcoma.
J. Robert Willson, Philadelphia, Management of Excessive Fluid Retention in Normal and Toxemic Pregnancies.

The Foundation Prize Thesis will be given by Dr. Thomas L. Ball, New York, on "Topographic Urethrography" and the *Joseph Price Oration by Mr. Charles D. Read, London, England,* on "Stress Incontinence of Urine" the evening of September 8. Dr. George F. Lull, Secretary, American Medical Association, Chicago, will speak on "National Legislation Affecting the Medical Profession" at the banquet September 9.

**Surgical Congresses.**—The Sixth Inter-American Congress of Surgery will meet as a part of the Thirty-Fifth Clinical Congress of the American College of Surgeons from October 17-21, with headquarters at the Stevens Hotel, Chicago, and will continue on October 21-23 with its own sessions, most of which will be held in the John B. Murphy Memorial Auditorium of the college. This will be the first time that the Inter-American Congress of Surgery has been held in the United States. The scientific sessions, scheduled for Saturday and Sunday afternoon, will center around three main themes: Acute Craniocerebral Trauma, with Dr. E. Jefferson Browder, Brooklyn, as the main speaker; Treatment of Injuries in the Region of the Ankle with Complications and Sequelae, with Dr. Harrison L. McLaughlin of New York as main speaker, and Pulmonary Carcinoma, with Dr. Evarts A. Graham, St. Louis, as main speaker. Each surgical society outside the United States and Canada which is represented will appoint a discussion leader, or correlator, for each of the themes. Between two and three hundred Latin-American surgeons are expected to attend the sessions, which will also be open to fellows from the United States and Canada. At the Clinical Congress of the American College of Surgeons Sir James R. Learmonth of Edinburgh will deliver the Martin Memorial Lecture October 17. Lord Webb-Johnson, London, president of the Royal College of Surgeons of England, will deliver the fellowship address at the convocation Friday evening. Television of operations in color from St. Luke's Hospital to the Stevens will be on each day's program during the Clinical Congress. Other events will include scientific sessions, official meetings, hospital conferences, medical motion picture showings, technical and scientific exhibits and operative and nonoperative clinics in the Chicago area.

**Prevalence of Poliomyelitis.**—*Reports of cases of polio*myelitis for the periods indicated have been received from the Division of Public Health Methods, U. S. Public Health Service:

Joan K. Barber, Brooklyn, to Dr. Frederic T. Kirkham Jr., of San Antonio, Texas, in Sea Girt, N. J., June 16.

Richard Michael Kafka, Tampa, Fla., to Miss Mary Elizabeth Nipher at Silver Springs, Md., June 5.

Richard Winston Thaler, Knoxville, Tenn., to Miss Victoria Louise Sears in Braintree, Mass., June 18.

William Ashley Cherry, New Orleans, to Dr. Flora Finch of McComb, Miss., June 9.

William Paul Doremus to Miss Barbara Madeline Wilcox, both of New York, June 12.

Albert Joseph Baroody, Columbia, S. C., to Miss Hazel Haskins of Ninety-Six, May 14.

William C. Feldman, Kingston, N. Y., to Miss Arline Karu in New York, June 18.

# Deaths

**Rafe Nelson Hatt,** Honolulu, Hawaii; born in West Paris, Maine, Nov. 11, 1889; Tufts College Medical School, Boston, 1918; member of the American Medical Association, American Orthopaedic Association and the American Academy of Orthopaedic Surgeons; fellow of the American College of Surgeons; served overseas during World War II; formerly member of the Massachusetts Public Health Council; chief surgeon at the Shriners' Hospital for Crippled Children; for many years practiced in Springfield, Mass., where he was past president of the Springfield Academy of Medicine, chief surgeon at the Shriners' Hospital for Crippled Children, and consulting orthopedic surgeon, Springfield and Wesson Memorial hospitals; in 1938 awarded the honorary degree of Master of Arts by the Colby College in Waterville, Maine; died May 27, aged 59, of coronary thrombosis.

**Walter Asahel Hoyt** ⊕ Akron, Ohio; born in Grass Lake, Mich., April 17, 1887; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1912; past president of the Summit County Medical Society; specialist certified by the American Board of Orthopaedic Surgery; in 1941 the American Medical Association awarded him the Certificate of Merit for an exhibit on the treatment of acute osteomyelitis with sulfathiazole without operation and in 1942 the American Academy of Orthopaedic Surgeons, of which he was a member, awarded him the gold medal for the same exhibit; member of the Clinical Orthopaedic Society; fellow of the American College of Surgeons; formerly on the professional advisory committee of the state welfare department; on the staffs of the City, Children's and St. Thomas hospitals; died May 31, aged 62, of carcinoma.

**Ira Bradford Chadwick** ⊕ Coffeyville, Kansas; born in Hamilton County, Iowa, Dec. 7, 1869; Medico-Chirurgical College of Kansas City, Mo., 1902; specialist certified by the American Board of Ophthalmology and the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; served during World War I; on the staff of the Coffeyville Memorial Hospital; died in the Veterans Administration Hospital, Muskogee, Okla., June 16, aged 79, of carcinoma of the cecum.

**Nelson Miles Black Jr.,** ⊕ Miami, Fla.; University of Pennsylvania School of Medicine, Philadelphia, 1939; served during World War II; for outstanding heroism displayed at Army Air Base APO 215 on Dec. 24, 1944, was awarded the Soldier's Medal; died June 9, aged 36.

**Charles Bock** ⊕ Los Angeles; Fort Wayne (Ind.) College of Medicine, 1897; died May 31, aged 79, of heart failure.

**Ritchie Lilburne Byrd,** St. Louis; Beaumont Hospital Medical College, St. Louis, 1899; died in De Paul Hospital June 22, aged 75, of heart disease.

**William Tenney Cannon,** Salt Lake City; Medico-Chirurgical College of Philadelphia, 1899; member of the American Medical Association; affiliated with the Dr. W. H. Groves Latter-Day Saints Hospital; died May 21, aged 78, of heart disease.

**Damase Caron,** Manchester, N. H.; School of Medicine and Surgery of Montreal, Faculty of Medicine of the University of Laval at Montreal, Canada, 1900; member of the American Medical Association; formerly mayor; affiliated with Notre Dame de Lourdes Hospital, Manchester, and the Hillsborough County General Hospital, Grasmere; died June 9, aged 73, of chronic myocarditis, bilateral lobar pneumonia, chronic nephritis and cardiorenal decompensation.

**Margaret Green Cartwright,** Albuquerque, N. Mex.; Woman's Medical College, Chicago, 1890; died in Mount Eden, Calif., April 28, aged 83.

**Rae Hazen Cather** ⊕ Barberton, Ohio; College of Physicians and Surgeons, Baltimore, 1914; affiliated with Citizens Hospital, where he died June 11, aged 61, of coronary occlusion.

**Elizabeth Francis C. Clark** ⊕ Ventnor, N. J.; Woman's Medical College of Pennsylvania, Philadelphia, 1909; member of the Medical Society of the State of Pennsylvania; served on the staff of Woman's Hospital in Philadelphia; died June 28, aged 69.

**Ralph Thurman Clark,** Springfield, Ill.; Northwestern University Medical School, Chicago, 1928; member of the American Medical Association; served during World War I; affiliated with St. John's Hospital and Memorial Hospital, where he died June 6, aged 53, of cerebral hemorrhage.

**Susan May Coffin,** Cochituate, Mass.; Boston University School of Medicine, 1910; member of the American Medical Association and the New England Pediatric Society; died June 1, aged 68.

**Charles James Cole** ⊕ Elkins Park, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1914; member of the American Academy of Pediatrics; served in France during World War I; died in the Abington (Pa.) Memorial Hospital June 22, aged 62.

**Albert J. Colton,** Buffalo; Niagara University Medical Department, Buffalo, 1890; member of the American Medical Association; invented the card index system bearing his name; affiliated with the Sisters of Charity Hospital; died June 18, aged 85, of heart disease.

**Patrick John Conroy,** Syracuse, N. Y.; University of the South Medical Department, Sewanee, Tenn., 1900; member of the American Medical Association; for many years associated with the medical department of the county welfare department; died June 11, aged 71, of heart disease.

**J. R. Crigler,** Alma, Ark.; Memphis (Tenn.) Hospital Medical College, 1900; member of the American Medical Association; affiliated with St. Edward's Mercy and Sparks' Memorial hospitals in Fort Smith; died May 7, aged 73, of left ventricular failure.

**Stephen James Dalton,** Brookline, Mass.; Tufts College Medical School, Boston, 1916; served during World Wars I and II; chief medical officer for the Veterans Administration in Boston; died in Wareham, Mass., May 11, aged 54, of carcinoma of the intestine.

**Arthur Putnam Derby,** Detroit; University of Virginia Department of Medicine, Charlottesville, 1904; member of the American Medical Association; served on the staff of the Herman Kiefer Hospital; died June 5, aged 71.

**Arthur Bland Donovan,** Boston; Tufts College Medical School, Boston, 1923; member of the American Medical Association and the National Gastroenterological Association; chief surgeon of the Lumbermen's Mutual Casualty Company; served on the staffs of Boston Lying-In Hospital, Harley Hospital and St. Margaret's Hospital, where he died June 22, aged 51.

**Samuel Bonner Eisler,** Brooklyn; Columbia University College of Physicians and Surgeons, New York, 1911; died May 22, aged 60.

**Samuel Elgart** ⊕ Cincinnati; Tufts College Medical School, Boston, 1938; specialist certified by the American Board of Internal Medicine; certified by the National Board of Medical Examiners; member of the American Diabetes Association and the Association for the Study of Internal Secretions; affiliated with Hamilton County Home and Chronic Disease Hospital, Cincinnati General Hospital and the Jewish Hospital, where he died June 18, aged 37, of heart disease.

**John Gustaf Ericson,** Minneapolis; University of Minnesota College of Medicine and Surgery, Minneapolis, 1892; affiliated with Swedish Hospital; fellow of the American College of Surgeons; died May 14, aged 81, of coronary thrombosis.

**Daniel Warren Evhans,** Yakima, Wash.; Marquette University School of Medicine, Milwaukee, 1944; interned at St. Joseph's Hospital in Milwaukee; served a residency in medicine at Methodist Hospital in Madison, Wis.; a lieutenant (jg) U. S. Naval Reserve during World War II, affiliated with St. Elizabeth's Hospital; died in Seattle, May 6, aged 32, of tuberculosis.

**George Benjamin Faulder** ⊕ Wapakoneta, Ohio; University of Michigan Homeopathic Medical School, Ann Arbor, 1914; served as member and president of the school board; an officer during World War I, serving overseas; affiliated with St. Rita's and the Memorial Hospital in Lima; died in the Toledo (Ohio) Hospital May 13, aged 57, of coronary thrombosis.

**Morris Feldman** ⊕ Chicago; Loyola University School of Medicine, Chicago, 1928; served during World War II; died June 21, aged 51, of coronary thrombosis.

**Joseph Leo Ferris** ⊕ St. Louis; St. Louis University School of Medicine, 1917; senior instructor in surgery at his alma mater; affiliated with the Alexian Brothers' and St. Anthony's hospitals and St. Mary's Group of Hospitals; died June 6, aged 58, of coronary disease.

**Ralph Mitchell Fouch,** Portland, Ore.; University of Nebraska College of Medicine, Omaha, 1921; member of the American Medical Association; died recently, aged 57, of heart disease.

**John William Freed,** Staunton, Va.; University of Virginia Department of Medicine, Charlottesville, 1901; member of the American Medical Association; affiliated with Western State Hospital; died June 2, aged 74.

### Clinical Study of Chagas' Disease

The Oswaldo Cruz Institute was established in 1944 at Bambuhy, state of Minas Gerais. This is a center for the study of American trypanosomiasis (Chagas' disease). Since then a clinicoepidemiologic survey of the population, which consists essentially of workers for the Rede Mineira Railroad and their families, has disclosed more than 600 patients with the disease; 103 had an acute form and 505 chronic. On the basis of this study, Dr. F. S. Laranja, Dr. Emmanuel Dias and Dr. Genard Nobrega, in charge of the Bambuhy center, have just published a valuable report on the clinical and therapeutic aspects of American trypanosomiasis, a disease which is gaining importance in the tropical and subtropical rural districts of the Americas.

The authors have made a revision of the clinical forms of the disease and suggest a new classification: (*a*) acute form and (*b*) chronic form: (1) chronic indeterminate form (potential heart disease) and (2) chronic cardiac form (chronic Chagas' heart disease). Nervous manifestations of the kind described as the chronic nervous form of schizotrypanosis have not been observed in the cases studied at Bambuhy. Clinical and experimental evidence supports the view that chronic Chagas' heart disease is a well established clinical entity. In the acute infection they stress that two kinds of edema may occur: local edema of the parasite's portal of entrance and generalized edema, the so-called "myxedema." According to their observations the generalized edema may be related to the presence of hypoproteinemia, while the local edema seems to be of inflammatory origin. The manifestations of acute Chagas' heart disease also are described. Gallop rhythm, enlargement of the cardiac shadow (in some cases due to pericardial effusion), prolongation of the P-R interval, primary T wave changes and ventricular premature contractions are the more important diagnostic signs of acute Chagas' heart disease. Right bundle branch block occurred in 3 fatal cases of acute Chagas' heart disease; in 1 of them a pronounced S-T displacement was also present. Death during the acute period of Chagas' disease is usually preceded by convulsions. The manifestations of the acute infection subside spontaneously and gradually in most cases; the disease then develops into the chronic stage and the patients become apparently cured, although still infected.

Patients with chronic infection and without evidences of heart involvement are considered potential patients with heart disease and classified in the group with the chronic indeterminate form of the disease. Infection remains in the organism, as a rule actively, and signs of heart involvement may develop later. Chronic Chagas' heart disease is usually a late manifestation of the infection. About 50 per cent of chronically infected patients present signs of heart involvement. The manifestations of chronic Chagas' heart disease depend on the severity of myocardial changes. Palpitations, dyspnea, convulsive-syncopal crisis (advanced auriculoventricular block), atypical precordial aches and pain in the upper part of the abdomen (liver congestion) are the commonest symptoms. Some cases do not present any symptoms; the heart is not enlarged, and the only evidence of myocardial damage is provided by the electrocardiogram (asymptomatic Chagas' heart disease). Irregularities of the cardiac rhythm, splitting of the second heart sound at the pulmonary area and gallop rhythm are common auscultatory findings. Heart enlargement involves all the cardiac chambers and is of variable degree. Patients with heart failure usually present pronounced heart enlargement. Signs of cardiac dilatation are predominant over those of cardiac hypertrophy. Signs of valvular deformity or structural changes of the large vessels are not found in this type of heart disease. Blood pressure is usually normal. Patients with heart failure may present reduced systolic pressure and small pulse pressure. Signs of functional valvular incompetence are common in patients with heart failure. Heart failure is usually of the right side or is bilateral, the isolated left side type of heart failure being rather uncommon. In the majority of instances the electrocardiogram reveals disturbances of impulse conduction and/or impulse formation. Ventricular premature contractions, right bundle branch block, auriculoventricular blocks of all degrees and atypical alterations of ventricular complexes are the most important electrocardiographic observations. Right bundle branch block is common in this type of heart disease and is of diagnostic value in endemic areas of schizotrypanosis.

Criteria for differential diagnosis with other types of chronic heart disease have been studied. Evolution of chronic Chagas' heart disease is variable, depending chiefly on the activity of the infection. Most patients die before 50 years of age. Prognosis depends in part on the degree of the enlargement of the heart, the degree of the reduction of the heart's functional capacity and the type of the existing arrythmia. Sudden death occurs commonly in this type of heart disease. Most of the deaths occur in heart failure.

An effective drug is not available for the treatment of Chagas' disease. Better results frequently are obtained with strophanthin than with digitalis in the treatment of heart failure of chronic Chagas' disease.

### Chagas' Disease and Blood Transfusion

Dr. J. Pellegrino reports for the first time the occurrence of Chagas' disease among persons serving as blood donors in Bello Horizonte, state of Minas Gerais. Three persons were found who exhibited strongly positive reactions to complement fixation tests (Schizotrypanum cruzi antigen). Formerly these persons lived in huts infested with Triatoma; 2 did not present signs or symptoms of Chagas' disease, but 1 showed heart trouble (right bundle branch block). The writer emphasizes the necessity for awareness of the dangerous possibility of the spread of Chagas' disease through blood transfusion. He suggests that the complement fixation test for S. cruzi be performed on all before they are admitted as blood donors in countries where the disease exists.

### Pneumonias in Asthenic Patients

Reports were presented before the medicosurgical association of the Romagna on pneumonia in asthenic persons and its treatment with antibiotics. Dr. Fontana of Ravenna demonstrated that the progress of anti-infectious therapy has contributed to progress in diagnosis through the criterion "ex adjuvantibus." This progress makes more necessary a rapid diagnostic orientation, thus making early intervention possible in certain diseases, by specific, highly effective treatment.

Pneumonia in old and debilitated persons is a typical example of such a morbid condition. In this group are patients with decompensated heart disease, diabetic patients and those who have had major surgical operations.

The clinical aspects of pneumonia in asthenic persons may include peculiarities which often make a diagnosis difficult; frequently the initial picture is one of grave cardiac insufficiency.

**Frank Lee Frink,** Newman Grove, Neb.; Louisville (Ky.) Medical College, 1891; member of the American Medical Association; formerly mayor and member of the school board; served during World War I; died June 6, aged 83.

**James Sterling Gilfillan,** St. Paul; University of Minnesota College of Medicine and Surgery, Minneapolis, 1897; University of Pennsylvania Department of Medicine, Philadelphia, 1898; member of the American Medical Association; formerly on the faculty of his alma mater; died in Miller Hospital June 13, aged 81.

**Samuel McPheeters Glasgow,** Nashville, Tenn.; University of Pennsylvania Department of Medicine, Philadelphia, 1895; assistant professor of clinical gynecology at the Vanderbilt University School of Medicine; fellow of the American College of Surgeons; member of the American Medical Association; served during World War I; for a short time city health officer and superintendent of the Nashville City Hospital; died May 31, aged 79, of coronary thrombosis.

**Harold Joseph Gondolf,** Austin, Texas; Tulane University of Louisiana School of Medicine, New Orleans, 1913; member of the American Medical Association; at one time on the faculty of the University of Mississippi School of Medicine, University; died June 3, aged 57.

**Daniel Henry Griffith,** Atlanta, Ga.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1911; died June 2, aged 65.

**Charles Nicholas Guhman** ⊕ St. Louis; Washington University School of Medicine, St. Louis, 1903; served during World War I; died June 6, aged 74, of heart disease.

**Oliver Overstreet Hammonds** ⊕ Oklahoma City, Okla.; University Medical College of Kansas City, Mo., 1900; formerly commissioner of the state health department; served in the U. S. Public Health Service; died May 20, aged 68, of carcinoma.

**Raymond Harris** ⊕ Ocilla, Ga.; University of Georgia School of Medicine, Augusta, 1937; served during World War II; died in the University Hospital, Augusta, June 1, aged 36.

**Frank Hill Hedges** ⊕ Frederick, Md.; University of Maryland School of Medicine, Baltimore, 1898; on the staff of the Frederick Memorial Hospital; died May 22, aged 78.

**Joseph Edmund Hillis,** Pryor, Okla.; University of Tennessee Medical Department, Nashville, 1900; died in Whitaker Hospital June 2, aged 73.

**Leo George Hogan** ⊕ Chicago; Bennett Medical College, Chicago, 1914; served during World War I; died in St. Bernard's Hospital June 18, aged 58, of papillary carcinoma of the kidney.

**Hal Rexford Hoobler,** Oakland, Calif.; Medical Department of the University of California, San Francisco, 1921; specialist certified by the American Board of Pediatrics; member of the American Medical Association and the American Academy of Pediatrics; affiliated with the Highland-Alameda County Hospital and Children's Hospital of the East Bay; director of the California State School for Deaf and Blind in Berkeley; died June 20, aged 60, of heart disease.

**Paris Robert Hysinger,** Chattanooga, Tenn.; Chattanooga Medical College, 1910; member of the American Medical Association; died in Erlanger Hospital May 18, aged 74, of injuries received in an automobile accident.

**Joseph Leland Kalfus** ⊕ Los Angeles; College of Physicians and Surgeons, Los Angeles, 1920; fellow of the American College of Surgeons; served on the staff of Our Lady of Perpetual Help Hospital in Santa Maria, Calif.; died in May, aged 60.

**Ernest Kelley** ⊕ Omaha; John A. Creighton Medical College, Omaha, 1907; professor and head of the department of nervous and mental diseases at his alma mater; specialist certified by the American Board of Psychiatry and Neurology, Inc.; fellow of the American College of Physicians; member of the American Psychiatric Association; on the staffs of St. Joseph's, St. Catherine's, Lutheran and Doctors hospitals; died May 14, aged 65, of heart disease.

**William August Klingberg** ⊕ Hope, Kan.; Rush Medical College, Chicago, 1901; past president of the Golden Belt Medical Society; served during World War I; retired as a lieutenant colonel in the reserve corps of the Army in 1945; died suddenly, May 10, aged 74, of coronary occlusion.

**Irl Brown Krause** ⊕ Jefferson City, Mo.; St. Louis University School of Medicine, 1921; member of the American Public Health Association; past president of the Missouri Tuberculosis Association; served during World War I; died May 29, aged 55, of coronary thrombosis.

**Aron J. Lauer** ⊕ Whiting, Ind.; Bennett Medical College, Chicago, 1893; an Associate Fellow of the American Medical Association; past president of the Lake County Medical Society; formerly secretary of the city board of health and member of the library board; affiliated with St. Margaret and St. Catherine's hospitals in Hammond; died April 30, aged 78, of coronary occlusion.

**Joseph Charles Lee** ⊕ Indiana, Pa.; Western Reserve University School of Medicine, Cleveland, 1929; fellow of the American College of Surgeons; on the staff of the Indiana Hospital; died in the Cleveland Clinic Hospital April 8, aged 44, of carcinoma.

**Marvin Eugene Leusley,** Covin, Ala.; Washington University School of Medicine, St. Louis, 1901; died May 22, aged 75.

**Joseph Cook Lovett** ⊕ Camden, N. J.; Jefferson Medical College of Philadelphia, 1911; medical director of the Municipal Hospital for Contagious Diseases; affiliated with Cooper Hospital, where he died May 31, aged 63, of hypertension.

**John Gilbert McDougal** ⊕ New Lexington, Ohio; Medical College of Ohio, Cincinnati, 1882; member of draft boards during World Wars I and II; died in the Good Samaritan Hospital, Zanesville, April 27, aged 89, of coronary thrombosis.

**James John Malcolm,** Chetek, Wis.; Trinity Medical College, Toronto, Ontario, Canada, 1900; served during World War I; died in St. Cloud, Minn., June 2, aged 74.

**Robert Prosser Morrow,** West Point, Ga.; University of Alabama School of Medicine, 1911; member of the Medical Association of the State of Alabama and the American Medical Association; died in the Valley Hospital May 30, aged 68.

**Joseph Moss,** Kankakee, Ill.; Loyola University School of Medicine, Chicago, 1918; died May 3, aged 74, of carcinoma of the stomach.

**Edward Lord Mulford,** Ithaca, N. Y.; Yale University School of Medicine, New Haven, 1931; member of the American Medical Association; affiliated with Hermann M. Biggs Memorial Hospital, where he died May 13, aged 47, of heart failure.

**Clayton Merchant Payne** ⊕ Alice, Texas; University of Louisville (Ky.) Department of Medicine, 1908; served during World War I; died April 8, aged 75, of coronary occlusion.

**Lewis Waite Pease,** Weymouth, Mass.; Tufts College Medical School, Boston, 1902; member of the American Medical Association; died in the South Shore Hospital recently, aged 73, of cerebral hemorrhage.

**Franklin Aborn Perkins,** Boston; College of Physicians and Surgeons, Boston, 1911; member of the American Medical Association; affiliated with the Harley Hospital; died in June, aged 65.

**Nilo C. Pintado,** Miami, Fla.; Universidad de la Habana Facultad de Medicina y Farmacia, Cuba, 1908; member of the American Medical Association; died in Coral Gables, June 11, aged 64, of coronary occlusion and hypertension.

**Jack Irving Rabens** ⊕ Chicago; Rush Medical College, Chicago, 1929; clinical associate in medicine at the University of Illinois College of Medicine; on the staff of Mount Sinai Hospital; died June 19, aged 46, of acute coronary thrombosis.

**Charles Franklin Smith** ⊕ Topton, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1911; past president of the Berks County Medical Society; served on the school board; vice president and director of the National Bank of Topton; affiliated with the Allentown (Pa.) Hospital, where he died June 4, aged 61, of congestive heart failure.

**Benjamin F. Swezey,** Buffalo, Minn.; Keokuk (Ia.) Medical College, College of Physicians and Surgeons, 1903; member of the American Medical Association; served as Wright County coroner and Buffalo health officer; died in Eitel Hospital, Minneapolis, June 2, aged 75, of heart disease.

**Harry Knibb Tebbutt Jr.,** ⊕ Albany, N. Y.; Albany Medical College, 1916; associate professor of otolaryngology at his alma mater; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology and the American Laryngological, Rhinological and Otological Society; served in France during World War I; for many years associated with Albany Hospital, where he died June 8, aged 57.

**Molyneaux Lawrence Turner,** St. Petersburg, Fla.; Long Island College Hospital, Brooklyn, 1893; fellow of the American College of Physicians; veteran of the Spanish-American War; died in the Veterans Administration Hospital, Bay Pines, June 6, aged 79, of carcinoma of the throat.

### Pneumonias in Asthenic Patients

Reports were presented before the medicosurgical association of the Romagna on pneumonia in asthenic persons and its treatment with antibiotics. Dr. Fontana of Ravenna demonstrated that the progress of anti-infectious therapy has contributed to progress in diagnosis through the criterion "ex adjuvantibus." This progress makes more necessary a rapid diagnostic orientation, thus making early intervention possible in certain diseases, by specific, highly effective treatment.

Pneumonia in old and debilitated persons is a typical example of such a morbid condition. In this group are patients with decompensated heart disease, diabetic patients and those who have had major surgical operations.

The clinical aspects of pneumonia in asthenic persons may include peculiarities which often make a diagnosis difficult; frequently the initial picture is one of grave cardiac insufficiency.

In the pathogenesis of the syndrome there are toxic and infectious factors which are fairly important but may often be only suspected; by cautious application of the criterion "ex adjuvantibus," it is highly probable that the patient's life may be saved.

The speaker reported the case of a patient with severe cardiac decompensation, who did not seem to present any infection but in whom definite improvement resulted from antibiotic treatment; previous cardiokinetic treatment had failed. The speaker emphasized the importance of an early "suspicion" in analogous cases; its practical importance is even superior to that of early (but erroneous) diagnosis. During the phase of early suspicion one can do nothing if one does not consider the "suspicion," but if one does one can proceed with other examinations and tests and also start life-saving treatment. Thus the fundamental problem of early diagnosis abides with early suspicion; the suspicion emanates only from careful medical examinations and may be assisted only by the good endowment of the physician.

Professor Giugni said that in a recent epidemic of influenza the antibiotics and the sulfonamide drugs were abused in cases in which there were no definite signs of bronchopulmonary localization, with the result that the local reserves of penicillin were depleted. He emphasized that the present wide distribution of these modern and effective therapeutic agents makes it too easy for one to forget the precious effect of digitalis, especially in cases of pneumonia in asthenic persons.

Professor Giugni said that one should suspect asthenic pneumonia especially in patients who suddenly suffer an attack of cardiac decompensation without previous history of cardiopathic changes. The "suspicion" may be transformed into nearly absolute certainty when a noteworthy improvement of the patient's condition results from treatment with sulfonamide drugs instituted on the base of such "suspicion" after the failure of cardiokinetic treatment.

### Optic-Chiasmal Arachnoiditis

In a meeting of the National Congress of the Italian Oto-Neuro-Ophthalmologic Society, Professor Di Marzio discussed optic-chiasmal arachnoiditis, an impairment of the region of the chiasm and of the emergence of the optic nerves. It is characterized (1) clinically by a complex of visual disturbances with campimetric and capillary changes and rapid diminution of vision and (2) anatomically by alterations of the optochiasmatic region, consisting in inflammatory lesions of the arachnoid which surrounds the chiasm and the first portion of the tract of the optic nerves.

The onset of symptoms is sudden, and the progressive diminution of vision is rapid. The visual field presents severe, early changes, generally bilateral and of irregular type. In the early stage the optic disk presents paripapillary edematous changes, with a slow tendency to atrophy in the second stage.

In addition to this type with acute onset, which occurs most frequently, one may observe the type with instantaneous blindness, which on first view does not show any changes of the *fundus oculi* and which may be confused with instantaneous blindness from other causes. In a case like this only lumbar puncture may provide precise orientation; no improvement may result in this type of blindness, while improvement results in blindness due to serous meningitis.

Arachnoiditis with a chronic course is associated with slow diminution of vision, which may be secondary to a central scotoma and reduction of the visual field or associated with horizontal hemianopia. Often these forms may be characterized by a rapid remission of the symptoms with partial spontaneous recovery, but after this improvement recurrences may be observed with a progressively severe course leading to blindness from optic atrophy.

In addition to early diagnosis, appropriate and timely treatment is important. In those forms in which the cause is known, causal treatment is advisable: arsphenamine and iodine given intravenously in syphilis; radiotherapy, vitamin $D_2$ and calcium given intravenously in tuberculosis, and operation on the sinus in cases of sinusitis.

When treatment of the cause may not be feasible, surgical intervention is advisable; it should be carried out early, since the benefit resulting from the operation is related to its timeliness. The speaker emphasized that the influence of surgical intervention on the course of the morbid condition is beneficial beyond doubt; in all his cases the progress of the process was arrested, and in the majority of the cases vision was improved definitely or even restored to normal.

### Plasmocytoma of Gamma Type

At the medicosurgical society of Verona, Dr. Colombo presented a patient with diffuse plasmocytoma of the gamma type demonstrated by the electrophoretic research carried out by Professor Wuhrmann of Zurich. The case presented difficulties in diagnosis; there were general signs of osteopathic changes, and a large swelling of one of the shoulders was observed which was considered to be an osteosarcoma. Explorative puncture immediately established the diagnosis. From the radiologic point of view, the case presented the peculiarities of typically myelomatous lesions (cranium and rips), close to the osteoporotic lesions (rickets), and a severe pseudosarcomatous aspect (humeral metaphysis). Serologically, strongly positive Takata, Ucko, Weltmann, Gaté-Papacostas and Wunderly (cadmium) reactions were observed.

The electrophoretic analysis carried out by Professor Wuhrmann demonstrated values as follows: albumin, 33.1 per cent; alpha globulin, 7.3 per cent; beta globulin, 5.1 per cent, and gamma globulin, 54.5 per cent (normal 14 to 18 per cent). Cytologic examination showed immature plasma cells and reticular plasmoblasts.

There was an unexpected and spontaneous remittance with progressive improvement in the course of three months of clinical follow-up without any specific treatment (irradiation, transfusions, antimony potassium tartrate, stilbene) which may be used today.

With respect to the possible mechanism of the improvement, the speaker alluded to the progressive allergic desensibilization (data recently elaborated by Zironi).

### Urinary Radiomanometry

In attempts to treat stenosis of the neck of the ureter, Leger, Caillet, Libaude and Weber applied, for the first time, urinary radiomanometry to study the functioning of urinary excretion. This new method consists in injecting into the urinary tract a radiopaque liquid, under an adjustable pressure, which remains constant whatever the output may be. The apparatus for biliary manometry, perfected by Caroli, is perfectly suitable for this purpose. The pyeloureteral filling is supervised under a screen, and the pressure at which the passage of the liquid is obtained is noted. The alimentation tube for perfusion is then squeezed, and thus the pyeloureteral cavity communicates with the manometer only, in which the pressure falls without reverting to zero. This residual pressure responds to the permanent tonus of the smooth pyeloureteral musculature, but is not sufficient to insure the evacuation in the bladder of the pyeloureteral content. The difference between the initial pressure and the residual one expresses, according to the authors, the tonicity particularly of the area of the ureteral meatus. The authors express the hope that this new method will enable one to pursue the study of the painful functional syndrome and perhaps permit the discovery of some still unknown pathologic change at the ureterovesical junction.

### Congresses

The ninth meeting of the association for physiopathologic studies of the liver and nutrition will take place in Vichy Sept. 16-18, 1949. On the agenda will be "Therapy of Migraines of Hepatic Origin." Application should be made to the secretary's office: 32 Avenue du Président Wilson, Paris (16).

The seventh congress of French-speaking electroradiologist doctors will take place in Paris Oct. 11-15, 1949. In radiology there will be a report on radiodiagnosis, the radiologic study of the inferior third of the esophagus (Jutras, Levrier and Longtin); in radiotherapy, leukemias and their treatment (Betoulieres and Marques); in electrology, modern theories on the excitability and the conductibility of nerves (Professor Degrez). Registrations are in charge of Dr. Cherigie, Assistant General Secretary, 9 Rue Daru, Paris (8).

### Treatment of Syphilis with Penicillin

Herxheimer's reactions and relapses following penicillin therapy caused a discussion on the value of this treatment at a meeting of the Medical Society of Paris Hospitals on April 29. M. Bolgaert, G. Levy, F. Faure and J. Aladenise never observed these serious accidents, as they previously administered daily injections of 0.01 Gm. of mercuric cyanide for three days and then gave 15,000,000 units of penicillin (1,000,000 units spread over three days and the 14,000,000 remaining units given within fourteen days). The 56 cases they observed included 6 cases of primary, preserologic syphilis, 17 cases of primary, seropositive syphilis and 33 cases of secondary syphilis; negative serologic responses have been obtained, except in 1 case of secondary syphilis; these groups have been under observation for a maximum of 560, 660 and 676 days, respectively. The tolerance for this treatment was perfect. While not drawing premature conclusions, the authors have emphasized that these results are hopeful and superior to those obtained by others. Degos noted 30 per cent relapses within the first eighteen months following two successive courses of 10,000,000 units, separated by a ten day interval; he considers that penicillin does not offer a sufficient guarantee to justify its exclusive use. In mixed (and conjugated) treatment with penicillin, arsenic and bismuth, the author did not notice any synergic action, contrary to experimental results in animals. Degos is in favor of treatment with penicillin alone for three days, followed by a classic course of twenty injections three times per week of oil-soluble bismuth. Tzank, disappointed in penicillin therapy of syphilis, has stressed the excellent results obtained with arsenobismuth therapy.

July 8, 1949.

### Unstable Equilibrium of Athletes

At a meeting of the Medical Society for Physical Education and Sports, Dr. Hustin made a report on the Olympic games in London and pointed out a number of facts to be considered by those responsible for the medical supervision of sports. He pointed out, not only on the basis of interpretation but on absolutely objective observations, how trained athletes become so specialized biologically that they cannot tolerate the slightest deviation. Every change in food, habits, mode of life and sleep is likely to modify to a noticeable extent their possibilities of performance. Continued training creates a person so artificially and narrowly specialized that in his case we have the right to inquire whether we are not dangerously deviating from the maxim "mens sana in corpore sano."

He discussed the anemia of athletes, which is not widely known, and then proposed to the Belgian Medical Society of Physical Education and Sports a study of the marathon, with the aim of finding out whether it would not be advisable to omit it from the Olympic program or at least to modify it; the problem of the diet of athletes with regard to the type of sport practiced should also be investigated.

### Medical Activity in Luxemburg

For nearly a year the Society of Medical Sciences of Luxemburg has developed satisfactorily. Its scientific meetings and its bulletin are a valuable combination. An editorial in the first number says, "The publication of the bulletin of our Society is a duty which we owe to our country. We are proud of our independence and we maintain it. Don't you think that our independence should manifest itself not only in the political sphere but likewise in the scientific field?"

The work which appeared in a recent number relative to medical inspection in the slag mill in Dudelange deserves attention. Fréderic Hippert recalls that the dust of slag is not likely to produce tuberculosis; nevertheless, it is necessary to provide for regular medical examination of the workers, but the prophylactic measure of greatest importance consists in the effort to make the places of work more conducive to health.

## IS THERE MERIT IN THE SO-CALLED "CEREBRAL PALSY" PROGRAM?

*To the Editor:*—Spastic paralysis and allied disorders of the central nervous system which must be considered in differential diagnosis have recently been widely publicized under the all-inclusive title of "cerebral palsy." An attempt is being made to establish expensive and elaborate training programs for the care of these patients in many of our crippled children's clinics. In some instances writers imply that such a program of muscle training and reeducation will afford continuous improvement in muscle control and function and will eliminate need for surgery to correct deformities even in selected cases. What can be expected from a program of this type?

My opinions are based on experience derived from study of a group of 2,096 consecutive cases seen prior to 1948 at the St. Louis Unit of the Shriners' Hospital for Crippled Children. These allied disorders of the central nervous system can be adequately classified under the four major headings shown in the table, which also shows the relative frequency with which each has been encountered. The classification into which each case falls is dependent on the clinical observations and manifestations, and these in turn are dependent on the portion of the central nervous system involved. The classification indicates that an all-inclusive term such as "cerebral palsy" is inadequate and nondescriptive. The use of a term of this type is comparable to the use of the term "rheumatism" in describing the various types of arthritis. Better would be a simple classification by which each case would be identified accurately according to the type of involvement.

The patients with a picture of spastic paralysis resulting from a pyramidal tract lesion comprise a large percentage of the total. This involvement may represent a simple uncomplicated spastic paralysis, but in many instances it is complicated by other clinical manifestations which are indicative of involvement of portions of the central nervous system other than the motor pathways. These manifestations are impaired sense of balance, impaired mentality, impaired speech, associated congenital athetosis or even associated epilepsy. These manifestations are of great clinical significance. The group with true spastic paralysis is the only one of the four in which surgical correction of deformities can be considered. Yet, for a patient to be suitable for surgery, there must be a satisfactory sense of balance and little or no associated athetosis. Speech and mentality should also be satisfactory if the child is eventually to become independent and self supporting. In this total series of 2,096 cases, of which 1,459 showed involvement of the pyramidal tract, only 546 patients could be considered suitable for surgical correction of the deformities which were present.

From a purely practical standpoint, all patients may be grouped under one of three headings: 1. Those in whom the involvement is mild, who do not require treatment and can be expected to take a normal place in society, remaining independent and self supporting. Approximately 25 per cent of the entire group can be so classified. 2. Those with moderate involvement and for whom much can be accomplished by reconstructive measures. This group also comprises about 25 per cent of the total number. 3. That large number of persons who show extensive involvement, from pyramidal tract lesions, extrapyramidal lesions, impaired mentality, cerebellar lesions or those with decided spasticity complicated by other associated conditions. These patients represent a type of involvement for which surgical reconstructive measures offer no hope of benefit, and little or nothing can be accomplished from any form of treatment. This large third group comprises about 50 per cent of the total number of cases.

Much has been written and said in recent years about the value of an elaborate training program for the management of these cases. In some instances elaborate institutions are being established for the care of the children to extend over a period of many years in order to furnish them with adequate supervised training and physical therapy. For the wealthy such a program is of course acceptable, not from the point of view of treatment and any benefit derived, but from the point of view of care which they can well afford. These institutions often attempt to establish as nearly as possible surroundings and facilities which are within the realm of the patient's physical abilities or, in brief, a country club for "spastics." Even some of the state crippled children's services have attempted to follow this pattern and establish facilities for the management of all cases of spastic paralysis or allied disorders of the central nervous system. Some spontaneous improvement invariably occurs in these patients and can be expected to continue through their adolescent years. This depends primarily on the normal development which takes place in the central nervous system. Much of the improvement which is credited to these specialized training programs may well be due to nothing more than the normal developmental processes which continue without regard to the treatment. The final picture in these patients as regards mentality, speech, sense of balance and the function of their involved extremities depends more on their normal developmental processes than on any combination of outside factors.

*Disorders of the Nervous System Observed at Shriners' Hospital, St. Louis*

| Type of Involvement | No. of Cases |
|---|---|
| Pyramidal tract lesions | 1,459 |
| Extrapyramidal lesions | 320 |
| Impaired mentality | 289 |
| True cerebellar lesions | 28 |
| Total | 2,096 |

The large third group, representing those with extreme involvement, offers a fertile field for the proponents of any program of training and muscle reeducation. This may be attributed partly to the fact that it is difficult or impossible to evaluate accurately the results obtained and still more difficult to know where credit for any improvement should be placed. The eternal cycle of changing therapeutic measures in those crippled children's problems which result from disease of the central nervous system is sufficient proof that we are clinicians, and orthopedists have more difficulty with these problems than with any other. We are impressionable and often influenced by suggestions which cannot be justified on the basis of the pathologic condition involved. The patient in this third group represents an extreme involvement of the central nervous system and in some instances an extreme developmental defect, which cannot be replaced or corrected under present medical accomplishments. Any program of muscle training and reeducation is merely tinkering with the peripheral, secondary manifestations and cannot be expected to alter the primary pathologic change. These patients may show some improvement in subsequent years, but this improvement will occur spontaneously from natural development.

Since so little can be accomplished by expensive and extensive training programs in the third group with extreme involvement, and since the first two groups do not need it, it seems unwise for any crippled children's organization to expend the vast sums of money which would be required to establish such a program. What is actually needed for this group of patients is the establishment of institutions where the everyday needs of the patient could be adequately met without any attempt at expensive training and rehabilitation. Our present institutions for the mentally incurable, representing principally the state asylums for the mentally disturbed, are not satisfactory for this type of patient and are so overcrowded that it is impossible to admit a patient even when the family consents. Institutions could be established which would give the care required by these patients without entailing a tremendous expense or large personnel. The patients themselves would be happier, since they would be in an environment which they would consider more normal with the type of involvement which they show and since they would be relieved of the strain resulting from their contact with the fast pace of everyday life. More than this, one of the greatest advantages resulting from adequate institutions of this type would be derived by the normal members of the family who remain at home. Any home with a child of this type seldom enjoys a normal home life. The patient often requires all of the time and care which the parents can give, frequently resulting in the neglect of the normal children who could hope to derive benefit from their guidance and counsel. It would seem wise therefore to discourage serious consideration of recent proposals calling for the establishment of elaborate and expensive training programs by the various state crippled children's services and other charity organizations. Efforts should be made instead to obtain establishment of institutions in which adequate everyday care could be given to patients who fall in the unfortunate third group.

H. R. McCarroll, M.D., St. Louis.

This letter was referred to Drs. Perlstein and Phelps, who reply:

*To the Editor:*—Some of the arguments set forth by Dr. McCarroll are logical, but would have more merit if his premises were as correct as his thinking. He states, for example, "In some instances writers imply that a program of muscle training and reeducation will afford continuous improvement in muscle control and function and will eliminate need for surgery to correct deformities even in selected cases: What can be expected of a program of this type?" The implication is, of course, that this quotation expresses the opinion of those who are most interested in furthering the "so-called cerebral palsy program." In actuality, however, nothing could be further from the truth.

Any program which limits itself to muscle training and reeducation or to surgical correction and ignores socialization, speech correction, education, occupational therapy and the correction of sensory, emotional and other defects is incomplete. Despite Dr. McCarroll's statement as quoted here, I do not believe it possible to find anyone experienced in the field of cerebral palsy who would say that surgery should never be performed in any case. I think that the opinion would be almost universal, however, that there has been too much surgical treatment in the past.

The extent of Dr. McCarroll's experience in cerebral palsy is evidenced by his statistics. These same statistics, however, indicate that his experience has been of a rather restricted nature. His incidence of cases with pyramidal tract lesions is over four times that of cases with extrapyramidal lesions, as would be expected in an orthopedic hospital where the surgical aspects of the problem receive the main emphasis. It is well recognized that deformities and muscle imbalances due to pyramidal tract lesions are more amenable to surgical correction than those due to extrapyramidal involvement. Similarly, convulsive seizures and defects in mentality are much more common with pyramidal tract lesions (with the exception of paraplegic cases) than with extrapyramidal involvement. However, in training centers or schools for the mentally educable cerebral palsied, at least 50 per cent of the children have extrapyramidal tract lesions, as they and the spastic paraplegic patients constitute the bulk of the educable cases.

Many of the children originally seen in screening neuropediatric clinics never get to orthopedic hospitals (1) because their physical involvement is so minimal that treatment is not indicated; (2) because many die or are institutionalized during the first few years of life, or (3) because many of the lesions are of the extrapyramidal type and not generally amenable to surgical correction.

The material, therefore, on which Dr. McCarroll bases his conclusions is not representative of the cerebral palsied children seen in a general pediatric or neuropediatric clinic.

The question arises as to whether the teaching of such persons is worth while in time, effort and money. It may be advantageous to teach even the patient who is severely handicapped mentally some degree of self help or locomotion, even though it may be necessary eventually to place him in an institution for the feebleminded. Not only does such a patient have a richer, more satisfying life, but the cost of his care is substantially reduced.

Although Dr. McCarroll decries the establishing of institutions which could be called "country clubs for spastics," he, himself, suggests that there is a need for custodial care institutions with as normal an environment as possible. I agree with both of his statements. Institutional care, in its simplest form, is expensive, nor is it desirable to place in custodial care any person who may be trained so that he may live satisfactorily outside an institution. The cost of rehabilitation of such a person and the cost to the family in terms of social and economic disability caused by having such a person at home must also be taken into consideration. Any service, however, which can to some appreciable degree rehabilitate such a handicapped person is worth considerable expense.

Dr. McCarroll points out that many children will improve without having any type of treatment. This is, of course, well known, and no honest doctor would fail to credit the natural developmental urges in children for their full share in rehabilitation. As a matter of fact, one should always take advantage of this phenomenon and therefore attempt to stimulate this inherent tendency to improve by an approach to the emotional as well as the physical disabilities that exist in the child.

The ineffectiveness of such service comes, first, from failing to take the complete point of view of the person as an individual and considering him only as one who has difficulties in speech or one who has only deformities of body or one who has only emotional or mental problems. As no single specialist can be qualified to treat all facets of the disease, a program must include a complete list of all the medical, psychologic and social services which are available in the community. To consider the surgical approach as the most important is just as fallacious as considering drug therapy the most important solution.

Second, one must not consider cerebral palsy as an isolated problem but as part of the whole problem of the handicapped child. The reason for the present emphasis on cerebral palsy is that this group represents the largest segment of forgotten or neglected handicapped children. The National Foundation for Infantile Paralysis has been able to supply funds for the other large groups of crippled persons. The National Society for Crippled Children, in its promotion of the cerebral palsy campaign, has stressed that its interest is providing service for the cerebral palsied as a part of the total program for the handicapped.

Third, the cerebral palsy program has been damaged and to a certain amount retarded by well meaning lay organizations which have attempted to set up programs without medical help. By the same token, it has been harmed by doctors who have specialties in a single field who have not sought the help of their fellow specialists in other fields as well as of social service workers and psychologists. A clarification of the problem is being sought by a group of doctors of many specialties who have banded together in the American Academy of Cerebral Palsy, where points of view on all aspects of the problem can be freely exchanged. It is the opinion of groups like this that a properly constructed and properly administered cerebral palsy program effectively gains for society more than it spends.

M. A. PERLSTEIN, M.D.
4743 N. Drake Ave., Chicago 25.

---

*To the Editor:*—I question some of Dr. McCarroll's statements. For example, the statement, "Much of the improvement which is credited to these specialized training programs may well be due to nothing more than the normal developmental processes which continue without regard to the treatment" and the following sentence are both unfounded statements of his opinion. Those who have worked with these specialized institutions over a period of years develop a different opinion in comparing cases treated by this method with cases not so treated.

The Shriners' hospitals do not have long time care as is well known; therefore patients cannot be followed in such a situation long enough to determine what the effects would be.

The conclusions in his last paragraph are based on his previous statements, of which he has no actual proof. He states, "Since so little can be accomplished by expensive and extensive training programs . . . etc." I think the fact that many states are undertaking to set up training programs for these patients and that most of this has been the result of observation by many of us in itself would indicate the value of such programs.

The cerebral palsied children who used to be brought to me five or six years ago had an average age of 6 or 7 years. At this age, I found many deformities due to postural conditions and in walking, such as contractures of the knees, tight heel cords, scoliosis, wrist drop and contracted hands.

Now that cerebral palsy has become so much better recognized, my average new patient age is between 1 and 2 years. I have found that, in most cases, by appropriate apparatus and training, most of the deformities seen in these older children previously untreated can be entirely prevented. This, I think, is an important phase of the picture.

There are adults that I have seen, previously untreated, in whom the lack of locomotion or use of the arms is entirely due to the deformities, and these persons could be useful and self sufficient had the deformity element been prevented in their early childhood.

In any plan it is well to present both sides of the picture, and on this basis I think that we should give some consideration to Dr. McCarroll's statements. However, I feel certain that the value of such programs has been definitely established and that in many instances the expense of setting them up does not need to be as great as he points out.

Winthrop M. Phelps, M.D., Baltimore.

---

## THE LEMPERT FENESTRATION OPERATION

*To the Editor:*—The editorial on the fenestration operation in The Journal of June 25 requires clarification on a few points.

In the discussion of the results reported by Shambaugh and Juers and Shambaugh the statement is made that their "estimate of prognosis has apparently been revised downward." This statement seems to be based on the 1946 report by these authors[1] of improvement in 92 per cent of cases in which audiometric measurements were made two years after operation, whereas in the 1947 and 1948 reports[2] two year successful results, with practical hearing to within 30 decibels loss for the speech frequencies, were obtained in 80 per cent of ideally selected cases.

These two reports of results are not comparable, since they referred to two different criteria of evaluation of results: the first referred to all patients operated on with respect to whether or not they showed a significant audiometric gain (of more than 10 decibels), and the second referred only to the ideally suitable cases with respect to the percentage of patients with practical hearing after two years. Actually a more recent report[2a] showed that 94 per cent of 415 patients tested two years or more after operation had audiometric improvement (of more than 10 decibels), so that the "estimate of prognosis" of these authors has not been revised downward.

There is as yet no universally accepted criteria for evaluation of the results of the fenestration operation. Both the percentage of patients who have a significant audiometric improvement and the percentage that reach a practical level of hearing are useful criteria.

The editorial further states, "Other authorities suggest that the 20 per cent difference in estimate of good prognosis (60 per cent by Lempert and 80 per cent by Shambaugh) probably does not relate to a real difference in operative results obtained or technics employed. . . ." That there is "no real difference in technics employed" is without foundation. The modified technic first described in 1946 by Shambaugh and Juers[3] includes certain original features, based on experimental studies, to prevent recession of the hearing improvement due to osteogenic closure of the fenestra. The most important of these features is the use of continuous irrigation and the operating microscope to create a fenestra immaculately free from any microscopic particle of bone dust. Two years later Lempert described his "bone-dust-free nov-ovalis technic."[4]

# Bureau of Medical Economic Research

## MISUSE OF AMERICAN MEDICAL ASSOCIATION DATA

FRANK G. DICKINSON, Ph.D.
Director, Bureau of Medical Economic Research
Chicago

*In the article that follows, the Director of the Bureau of Medical Economic Research denies the claims of certain prominent advocates of compulsory sickness insurance that the Bureau of Medical Economics in 1939 stated that families with incomes of less than $3,000 a year could not afford to pay the costs of a "serious illness." These advocates apparently misinterpret the chart on page 90 of the pamphlet "Factual Data on Medical Economics" published in 1939 and revised in 1940 by the Bureau of Medical Economics. Even if the chart were not misinterpreted, the claims of these advocates cannot be supported now. There has been a reduction in the percentage of families with an annual income of less than $4,800, the present equivalent in buying power of $3,000 a decade ago; also the current test for many persons is inability to prepay about 20 cents a day—the price of a package of cigarets, a bottle of beer or a gallon of gasoline—as contrasted with the ability to postpay in the 1930's, before the rapid development of voluntary health insurance in the 1940's. A statement on inability to pay that uses a family income level without reference to the age composition of the family is unscientific. The term "medical indigency" can be defined only at the local level with qualifications to meet local conditions.*—Ed.

Dr. Channing Frothingham, Chairman of the Committee for the Nation's Health, stated recently: "The AMA's own statistics show that 80 per cent of the population—all those with incomes under $5,000 a year—are not able to meet the expenses of serious illness out of their own resources."[1] Testifying before the Senate Committee on Education and Labor, Dr. Allan M. Butler, associate professor of pediatrics at the Harvard Medical School, said, "The American Medical Association agrees that patients whose family income is $3,000 per year cannot pay the costs of serious illness."[2] Seymour E. Harris, professor of economics, Harvard University, made the following statement before the Senate Subcommittee of the Committee on Labor and Public Welfare, "Actually in 1939 the AMA estimated that families with incomes under $3,000 could not afford a serious illness. This is the equivalent of $5,000 today and, therefore, the AMA estimate suggests help for 80 per cent of all families."[3] Time and time again, advocates of compulsory sickness insurance cite these figures as American Medical Association's statistics, but do not mention the publication in which they were found. So far as we have been able to determine, the statements attributing these figures to the American Medical Association stem from a cursory analysis of a chart and a few lines of text appearing on pages 90 and 91 of "Factual Data on Medical Economics," published in 1939 and revised in 1940 by the Bureau of Medical Economics of the American Medical Association. When asked to cite a source for his statement, Dr. Frothingham wrote (March 14, 1949) the

---

*The publications of the Bureau of Medical Economics from 1931 to September 1946,* when the name was changed to the Bureau of Medical Economic Research and the present Director was appointed, were searched by research assistants on the Bureau staff. Likewise the proceedings of the House of Delegates and the articles and editorials in The Journal of the American Medical Association since 1930 were examined. Janice Oberman, Research Assistant, did most of this searching and assisted in other ways in the preparation of this article. This statement has been read and approved by Roscoe G. Leland, M.D., who was the Director of the Bureau of Medical Economics from its inception in 1931 until his retirement in 1944.

[1] AMA's Health Program Branded "Fancy Publicity," Chicago Daily Tribune, Feb. 21, 1949 (Associated Press dispatch).

[2] Hearings Before the Committee on Education and Labor, United States Senate, Seventy-Ninth Congress, Second Session on S. 1606, pt. 1, April 1946, p. 412.

[3] May 25, 1949, on behalf of Americans for Democratic Action; mimeographed.

following paragraph in which he partially qualified the statement in the Associated Press dispatch already noted:

> My belief is further strengthened by the interpretation by those in whom I have faith of the chart on page 90 of the American Medical Association's pamphlet to which you refer, "Factual Data on Medical Economics," 1939. (I have not the revised 1940 copy.) It appears that the American Medical Association's officers responsible for that chart believed that persons who in 1939 had incomes under $3,000 a year could not meet "major illness" expenses without "sometimes needing help." Today, with the change in money values, $3,000 must be translated into over $5,000.

On page 68 of *The Nation's Health* (A Report to the President by Oscar R. Ewing, Federal Security Administrator, September 1948) appears the following statement which actually uses two of the terms of the chart, namely, "major" and "chronic" illness:

> As long ago as 1939, the American Medical Asociation estimated that an income of $3,000 a year was not adequate to pay the costs of a major or chronic illness. Since then, the consumers' price index has risen approximately 75 per cent. A family would need take-home pay of more than $5,000 to have the same spending power that $3,000 gave in 1939. Nearly 80 per cent of our families earn less than $5,000 and consequently would have difficulty meeting the costs of a serious or prolonged illness.

### 1939 CHART MISINTERPRETED

*The chart does not support Dr. Frothingham's statement; nor* does it support the statements made by other advocates of compulsory sickness insurance. (The chart on page 90 [fig. 1] and the comment on the chart on page 91 [fig. 2] are reproduced herewith as they were printed originally except that rows are lettered A to D upward and columns 1 to 5 across.) The chart, as well as the comment, indicates clearly that the indigent (row A—no income) are a community responsibility; no mention is made of responsibility at the federal (or state) level. Families receiving less than $1,500 per year (which is the meaning of row B of the chart) can pay the cost of some of their minor illnesses (column 1) and some of their major illnesses (column 2) but must have public aid for chronic illnesses (column 3), institutional care (column 4) and the prevention of illness (column 5). In fact, the chart indicates that for all income groups below $3,000 (rows A, B and C) institutional care (column 4) and prevention (column 5) can be provided by proper coordination of existing agencies; further reference to the two vertical columns for institutional care and prevention is therefore unnecessary. Members of the income group $1,500 to $3,000 (row C) are for the most part self sustaining for minor illnesses (column 1) and largely self sustaining for major illnesses (column 2). They, too, need help for chronic illnesses (column 3). Members of the income group of $3,000 or above (row D) are self sustaining.

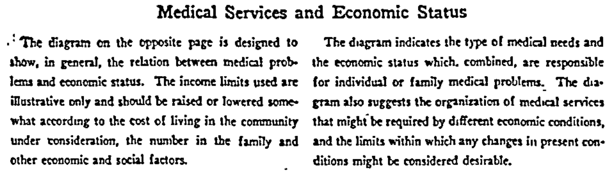
Fig. 1.—Chart of medical services and economic status, reproduced from "Factual Data on Medical Economics," page 90.



Medical Services and Economic Status

The diagram on the opposite page is designed to show, in general, the relation between medical problems and economic status. The income limits used are illustrative only and should be raised or lowered somewhat according to the cost of living in the community under consideration, the number in the family and other economic and social factors.

The diagram indicates the type of medical needs and the economic status which, combined, are responsible for individual or family medical problems. The diagram also suggests the organization of medical services that might be required by different economic conditions, and the limits within which any changes in present conditions might be considered desirable.

Fig. 2.—Reproduction of the comment on the chart, from "Factual Data on Medical Economics," page 91.

Clearly, then, the Bureau publication "Factual Data on Medical Economics" does not use the term "serious illness," which is the term employed by these advocates; instead the terms used are minor, major and chronic illness. These advocates should have used the same words or made their substitutions clear. Since this publication is a compilation of charts, tables and brief text explanations, these advocates might have examined earlier Bureau publications for fuller discussions of the tables and charts.[4]

In 1941 another publication of the Bureau of Medical Economics reflected the rising cost of living in the statement, "The dividing line above which income may be considered sufficient to meet the cost of medical care is probably about $2,000" (Basic Principles of Medical Economics, American Medical Association, p. 51).

The frequency and total cost of minor, major and chronic illnesses should have been indicated on this checkerboard chart by different widths of the vertical bars. (Furthermore, row A should have been black instead of white.) The chart would then have clearly shown that minor illnesses, which are largely sustainable by all income groups, account for the greatest portion of all illnesses. Since prevention, as used in the chart (column 5), is primarily a matter for public health service agencies rather than the individual, it does not present an economic problem for individuals and its inclusion in this chart is additional evidence that the chart does not really define medical indigency.

Most references being made currently to these two pages by advocates of compulsory sickness insurance misinterpret this chart for one reason or another. The chart does not show that families with incomes below $3,000 cannot afford medical care; it indicates only that for chronic illnesses (as well as for institutional care and for prevention), some families of incomes below $3,000 present a problem for public aid and some families do not. The chart would not completely support their claims if they had used a figure of $1,500 ($2,500 now) instead of $3,000 ($5,000 now). In fact, this checkerboard chart does not provide any clearcut income level for definition of inability to pay the costs of a "serious" illness. When one considers the relative infrequency of chronic illnesses as compared with the high frequency of minor illnesses and the relative frequency of major illnesses, the deception practiced by those who misuse this chart is evident.

---

[4] For example, it is stated in Organization of Medical Services, American Medical Association, Bureau of Medical Economics, 1937, pp. 7-8 (reprinted with additions, from the A. Med. A. Bull. **31**: 117-120 [May]; 125-131 [June]; 149-152 [Oct.] 1936): All of the upper income classes (above $3,000) may be assumed to constitute no important problem. They are already cared for under the traditional system of private practice, with existing facilities. The same is true for the great majority with incomes between $1,500 and $3,000 annually. Only cases of prolonged illnesses, or a series of serious illnesses in the same family, or the occurrence of such illnesses in connection with other unexpected expenditures should throw any members of this income division into the problem class.

Nearly all of the discussion of medical service plans is focused on those with incomes below $1,500. It must be remembered that this is a considerable class. It includes about 35 per cent of the nonfarming class and 72 per cent of the farmers.

Not all of these, however, constitute any special problem. A large percentage are able to pay for their medical care in the same way that they meet exceptional expenses in other lines.

Below these is the indigent class. This class is not fundamentally, and certainly not exclusively, a problem for the medical profession. The care of the indigent is a broad social problem. It is no more the problem of physicians than of any other citizens, except in the field of medical service. This is a large and, for the medical profession—especially during recent years—an extremely important field. It involves cooperation with public authorities and philanthropic organizations; and the function of the medical profession is principally to see that the quality of the medical service is maintained and that care of the indigent does not become an entering wedge for the introduction of undesirable methods of control and distribution of medical service.

Except for the indigent there is no important problem in the care of minor diseases. The economic difficulty arises at the point where major illnesses are combined with low incomes.

The problem of the care of the chronic ill is so largely economic as to be scarcely the main concern of the medical profession. The care of the chronic invalid depends on providing sufficient economic relief to provide support and medical care.

Neither do institutional cases demand any special new plans for their care. Here the function of the medical profession is to see that the care of the mentally diseased, the blind, crippled, or any others for whom institutional care is deemed necessary receive good medical service, free from political influence.

Preventive care runs across all income classes and many types of illness. Again, this is a field in which the main problem is the development and improvement of existing institutions. In this field public health, nursing and the private practice of medicine must combine their efforts. The problem is largely one of keeping clear the line of division and creating the most efficient forms of cooperation between each of these.

### MEDICAL COSTS HIGH, FOOD LOW

Any analysis of the question of medical indigency cannot be complete or meaningful without consideration of the composition, particularly with respect to age, of the families concerned. The needs of a family undergo constant change as the members of the family grow older. The typical young family, with the mother of child-bearing age, experiences the maximum medical needs. These needs decrease as the family grows older and rise rapidly again when the parents enter old age. The demands for food and clothing, however, follow a different pattern; they are usually at their maximum for parents in early middle age with grown children not yet married. Thus, when medical care expenses are at their maximum, food and clothing expenses tend to be at a minimum. Young fathers have not reached their maximum earning years; they are in the low income groups. The peak years of medical expense before old age, therefore, typically coincide with the years of low earnings for the young family. But these are also the years of low food and clothing expenses. These young families may have great medical expenses and low incomes, but they are more able to pay these expenses because their other living expenses will not reach their maximum until later in life. Obviously, then, a consideration of the income level alone cannot give enough information to determine medical indigency. Families in the same income group differ greatly in respect to their ability to afford medical care, and this difference arises out of the different age compositions of the families concerned. Income alone does not provide an adequate yardstick. The chart, as well as those who misuse the chart, overlook this changing relationship between medical and other family needs as the family grows older and its income rises until the breadwinner passes the earning peak later in life (at about age 45 to 55).

### FEWER LOW INCOME FAMILIES

Even if this chart had not been misinterpreted, its validity could not be the same today as at the time it was developed. The many changes that come about in time have undoubtedly altered its significance. One important change which would influence any interpretation of this chart is the change in the income distribution which occurred during the 1940's. According to the United States Bureau of Labor Statistics,[5] the Consumers' Price Index, which was 100 in 1935-1939, was 159.2 in 1947, the date of the latest available income distribution figures. As this price level has risen, the percentage of families in low income groups has declined. If the income figure of $3,000 is adjusted for the higher price level, an income of $4,800 ($4,776) in 1947 would be equivalent to the $3,000 income of 1935-1939 in purchasing power. That is, an income of $4,800 in 1947 would enable a family to purchase the same amount of goods and services it could have purchased in 1935-1939 with an income of $3,000. Dr. Frothingham and Professor Harris have rounded this figure to $5,000, which is admittedly more convenient than $4,800. The percentage of families with an income of less than $3,000 in 1935-1936 was 92.[6] In 1947, however, the percentage of families with incomes of less than $4,800 was approximately 79; under $5,000, the percentage was 81 and under $2,500, only 39.[7] It is evident, then, that the percentage of families in what was considered a low income group in the 1930's was considerably larger (92 per cent vs. 79 per cent) than the percentage in a comparable income group in 1947.

### POSTPAY THEN, PREPAY NOW

With the coming of Blue Cross and Blue Shield insurance plans and those developed by the insurance companies, the test of inability to pay has been utterly and completely changed. The emphasis today in the purchase of medical care is on prepayment, as contrasted with the concept of postpayment of former times. The test of the ability to pay for the type of medical care covered by Blue Cross and Blue Shield policies, especially in the case of major illness (column 2) is the ability of a family to prepay the premium for a combined Blue Cross-Blue Shield hospital and medical insurance policy for the entire family. The cost of this family policy is the price of a package of cigarets, a bottle of beer or a gallon of gasoline a day. In other words, any family that cannot prepay about 20 cents a day (the number of income earners per family averages more than 1⅓) may be considered medically indigent in 1949 with respect to the medical care provided under these policies. Before the development of voluntary insurance plans, the test of the ability to pay medical care bills ran up to several hundred dollars—the cost of postpayment in a lump sum or in installments. As long as the American people continue to choose to pay half again as much for alcoholic beverages and half again as much for recreation as they do for all types of medical care and choose to spend as much for jewelry and watches, more for personal care and twice as much for tobacco as they pay for their physicians, the advocates of socialized medicine in 1949 will be hard pressed to use the setting of the 1930's, even using $5,000 instead of $3,000 as the income level, for measuring or computing the proportion of the population which cannot prepay the cost of medical care. The ability to "prepay" and "postpay" are simply two different ideas of two different decades. Furthermore, the costs of the early part of chronic illness are met by voluntary insurance, and a long illness is one of the "rainy days" for which the American people have accumulated a large amount of savings.

### MEDICAL INDIGENCY DETERMINED LOCALLY

In general, it is very difficult, if not altogether impossible, to set any rigid income standard for determining who are medically indigent. Definitions of this term differ so greatly that it can scarcely be used without modifications to meet local conditions and changing times. In fact, few written definitions can be found in the literature on medical economics. Under the Maryland Medical Care Program which was established in 1945, the medically indigent are defined as follows:

> A person is medically indigent when he is unable in the place in which he resides, through his own resources, to provide himself and his dependents with proper medical, dental, nursing, hospital, pharmaceutical, and therapeutic appliance care without depriving himself or his dependents of necessary food, clothing, shelter, and similar necessities of life, as determined by the local authority charged with the duty of dispensing relief for the medically indigent.[8]

*Adopted and Recommended Annual Income Scales for Determining Medical Indigency*

| | Annual Income Scale | | | | |
|---|---|---|---|---|---|
| Number of Persons Supported by the Income | Adopted by the Council | Recommended by Committee of Council of Social Agencies | | | Department of Public Welfare Scale for Hospitalization |
| | | A | B | C | |
| 1 | $ 900 | $1,270 | $1,463 | $1,656 | $1,525 |
| 2 | 950 | 1,321 | 1,515 | 1,708 | 1,575 |
| 3 | 1,050 | 1,508 | 1,652 | 1,821 | 1,725 |
| 4 | 1,250 | 1,798 | 1,966 | 2,110 | 2,050 |
| 5 | 1,500 | 2,110 | 2,274 | 2,422 | 2,350 |
| 6 | 1,700 | 2,429 | 2,573 | 2,742 | 2,675 |

[6] Statistical Abstract of the United States, United States Department of Commerce, 1940, p. 316.

[7] Computed from data in Current Population Reports—Consumer Income, Series P-60, no. 5, United States Department of Commerce, Feb. 7, 1949, p. 17.

[8] The Maryland Medical Care Program—A Report to the Subcommittee on Medical Care, American Public Health Association, New York, 1948, p. 38. Although no reference was cited, this definition was taken from the proceedings of a Special Session of the House of Delegates of the American Medical Association held in Chicago, Sept. 16-17, 1938.

Decisions as to what constitutes "necessary" food, clothing and shelter, and as to when a person would have to deprive himself of these items in order to purchase medical care certainly must differ with individual values and local conditions. It is evident that the developers of the Maryland Plan foresaw this difficulty and consequently left these decisions primarily to the discretion of the local authority.

An income scale to determine medical indigency was also adopted under the medical care program in Maryland, the only recent income scale I have located. Again the local authorities were authorized to adjust this income scale to meet local conditions. It is also interesting to note that the scale adopted was considerably lower than any of those recommended by the Council of Social Agencies and the department of Public Welfare in Maryland (table). Both the adopted and recommended scales are, nevertheless, still lower than the $3,000 level and far below the $5,000 level mentioned by Dr. Frothingham and Professor Harris, and these scales are based on recent cost of living data.

### SUMMARY

I stress the following points about the misuse of data published by the American Medical Association, particularly by the Bureau of Medical Economics:

1. Certain advocates of compulsory sickness insurance have misinterpreted the chart on page 90 of "Factual Data on Medical Economics."
2. Neither their statements nor the chart show the influence of the age composition of a family on its ability to afford medical care.
3. They have applied the chart to a period in which it is no longer meaningful.
    - (*a*) They have failed, therefore, to tell the story of the difference between the test of ability to prepay today and the test of ability to postpay in the 1930's.
    - (*b*) They have not taken into consideration the changing income distribution in the United States and its effects on the definition of medical indigency.
4. They are using a term, medical indigency, which at its best, is ambiguous and arbitrary and of no significance unless qualified in respect to local conditions and individual differences.

# Medical Examinations and Licensure

## COMING EXAMINATIONS AND MEETINGS

### NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: *Parts I and II.* Various Centers. Sept. 12-14. Exec. Sec., Mr. E. S. Elwood, 225 S. 15th St., Philadelphia 2.

### EXAMINING BOARDS IN SPECIALTIES

American Board of Anesthesiology, Inc. *Oral.* Denver, Oct. 16-20. Sec., Dr. Curtiss B. Hickcox, 745 Fifth Ave., New York 27.

American Board of Dermatology and Syphilology, Inc.: *Written.* Various Centers, Sept. 15. *Oral.* Cincinnati, Oct. 21-23. Sec., Dr. George M. Lewis, 66 East 66th St., New York 21.

American Board of Internal Medicine: *Written.* Oct. 17. Asst. Sec.-Treas. Dr. W. A. Werrell, 1 Main St., Madison 3, Wis.

American Board of Neurological Surgery: *Oral.* Chicago, June 3. Final date for filing applications is Jan. 1. Sec., Dr. W. J. German, 789 Howard Ave., New Haven.

American Board of Obstetrics and Gynecology, Inc. *Part I.* Various Centers. Feb. 3. Final date for filing application is Nov. 5. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh.

American Board of Ophthalmology: St. Louis, Oct. 15-19; Boston, April. Sec., Dr. Edwin B. Dunphy, 56 Ivie Rd., Cape Cottage, Maine.

American Board of Orthopaedic Surgery. *Part II*, New York City, Feb. 9-10. Final date for filing application for Part II is Aug. 15. Address: Sec.-Treas., Dr. Harold A. Sofield, Room 1856, 122 S. Michigan Ave., Chicago.

American Board of Otolaryngology: Chicago, Oct. 4-7. Sec., Dr. D. M. Lierle, University Hospitals, Iowa City.

American Board of Pathology: Chicago, Oct. 7-8. Final date for filing application is Sept. 1. Sec., Dr. Robert A. Moore, 507 Euclid Ave., St. Louis.

American Board of Pediatrics: *Oral.* Cleveland, Sept. 16-18; New York City, Oct. 21-23; Chicago, Dec. 9-11. Sec., Dr. John McK. Mitchell, 6 Cushman Road, Rosemont, Pa.

American Board of Plastic Surgery: Examinations are given in June and November of each year in the home town of applicants. Sec.-Treas., Dr. Louis T. Byars, 400 Metropolitan Bldg., St. Louis, Mo.

American Board of Preventive Medicine and Public Health: *Parts I and II.* New York, Oct. 22-24. Final date for filing application is July 22. Sec., Dr. Ernest L. Stebbins, 615 N. Wolfe St., Baltimore.

American Board of Proctology: November. Sec., Dr. Louis A. Buie, 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Psychiatry and Neurology, Inc. *Special Examination.* Chicago, Oct. 24-25. December, New York City. Final date for filing applications is Sept. 15. Sec., Dr. F. J. Braceland, 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Radiology: *Oral.* Cincinnati, Sept. 28-Oct. 2. Sec., Dr. B. R. Kirklin, 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Surgery: *Written.* Various Centers, October 26. Sec., Dr. J. Stewart Rodman, 225 S. 15th St., Philadelphia.

American Board of Urology: *Written.* December. *Oral and Clinical.* Chicago, Feb. 11-15. Final date for receipt of case histories is Sept. 1, 1949. Sec., Dr. Harry Culver, 7935 Sunnyside Road, Minneapolis 18.

### BOARDS OF MEDICAL EXAMINERS

Alaska:* Juneau, Sept. 6. Sec., Dr. W. M. Whitehead, Box 140, Juneau.

Alabama: *Examination.* Montgomery, June 27-29. Sec., Dr. D. G. Gill, 519 Dexter Avenue, Montgomery.

Arkansas:* *Examination.* Little Rock, Nov. 3-4. Sec., Dr. Joe Verser, Harrisburg. *Eclectic.* Little Rock, Nov. 3. Sec., Dr. Clarence H. Young, 1415 Main St., Little Rock.

California: *Examination.* Los Angeles, Aug. 15-18. Sec., Dr. Frederick N. Scatena, 1020 N Street, Sacramento.

Alaska: Juneau, Aug. 28. Sec., Dr. C. Earl Albrecht, Box 1931, Juneau.

Arizona: *Examination.* Tucson, Sept. 20. Sec., Mr. Francis A. Roy, Science Hall, University of Arizona, Tucson.

Arkansas: *Examination.* Little Rock, Oct. 4. Sec., Mr. L. E. Gebauer, 1002 Donaghey Bldg., Little Rock.

Colorado: *Examination.* Denver, Sept. 14-15. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver 3.

District of Columbia: Washington, Oct. 24-25. Sec., Dr. G. C. Ruhland, 4130 E. Municipal Bldg., Washington.

Florida: *Examination.* Gainesville, Nov. 5. Sec., Mr. M. W. Emmel, University of Florida, Gainesville.

Michigan: *Examination.* Detroit and Ann Arbor, Oct. 14-15. Sec., Miss Eloise LeBeau, 101 N. Walnut St., Lansing 15.

Minnesota: *Examination.* Minneapolis, Oct. 4-5. Sec., Dr. Raymond N. Bieter, 105 Millard Hall, University of Minnesota, Minneapolis.

Nebraska: *Examination.* Omaha, Oct. 4-5. Director, Bureau of Examining Boards, Mr. Oscar F. Humble, Room 1009, State Capitol Bldg., Lincoln 9.

Oregon: Portland, Sept. 10 and Dec. 3. Sec., Mr. Charles D. Byrne, State Board of Higher Education, Eugene.

South Dakota: Vermillion, Dec. 2-3. Sec., Dr. Gregg M. Evans, 310 E. 15th St., Yankton.

Wisconsin: Milwaukee, Sept. 24 and Dec 3. Sec., Prof. W. H. Barber, Ripon College, Ripon.

# Current Medical Literature

## AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1938 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Developmental Opacities of Teeth in New England Community: Their Relation to Fluorine Toxicosis. V. O. Hurme.—p. 61.

**Vitamin D Preparations in Premature Infants.**—Glaser and associates studied the efficacy of four vitamin D preparations in preventing rickets and allowing normal growth in 166 premature infants for the first eight months of their lives. The preparations were (1) vitamin $D_2$ made by electron bombardment of ergosterol, (2) viosterol, which is vitamin $D_2$ made by ultraviolet irradiation of ergosterol, (3) crystalline vitamin $D_2$ and (4) "delsterol" (vitamin $D_3$), made by irradiation of 7-dehydrocholesterol. The dosages used were 100 units, 200 units, 400 units and 800 units daily. No clinical rickets were observed. Roentgenographic evidence of rickets occurred in 7 infants; in 2 others there was suspicious bowing of the extremities. Phosphatase levels above 15 Bodansky units per hundred cubic centimeters occurred in 29 instances, of which 23 were unaccompanied with evidence of rickets. It is believed that 20 units per hundred cubic centimeters represents a better normal upper limit for premature infants. With this limit, 12 instances of elevated phosphatase levels occurred, 10 of which were in the groups receiving 100 and 200 units. Serum calcium and phosphorus concentrations were almost always at high normal levels, even in the presence of roentgenographic evidence of rickets. Gain in weight and length was good in all 166 infants, regardless of the dosage or the type of vitamin D used. There appeared to be no difference in the efficacy of the vitamin D preparations in preventing rickets or in allowing growth. Though 100 units of vitamin D is a satisfactory prophylactic dose for most premature infants, 400 or 800 units daily allow a greater margin of safety in cases of illness or temporary neglect.

**Whooping Cough Treated with Immune Serum.**—According to Lucchesi and LaBoccetta it is generally recognized that whooping cough is severest and has the highest mortality rate in children under 1 year of age. For this reason, only children up to 12 months of age were included in this investigation. Only those for whom the diagnosis of whooping cough was confirmed by laboratory studies and by clinical evidence were studied. Patients were divided into two groups; each group included the alternate patients admitted without selection. Except for pertussis immune serum (human), the patients in group 1 were treated as those in group 2, the control group. Treatment consisted of sedation, aspiration and administration of sulfonamide drugs and/or penicillin for bacterial complications, oxygen and a mixture of 5 per cent carbon dioxide and 95 per cent oxygen. The patients who received serum showed a more regular decline in the rate of frequency of paroxysms when treated in the first week of disease than did the patients in the control group. The difference was not as noticeable when treatment was started in the second week of disease. In both instances, the difference was not apparent until after the second seven day period after hyperimmune serum had been given. The serum did not materially affect the rate of decline of the frequency of paroxysms in patients with bronchopneumonia as compared with controls. The temperature remained elevated longer in patients treated with serum than in the control patients.

**Electrocardiogram in Myocardial Infarction.**—The cases studied by Failey fall into 2 groups, the first comprising 100 patients in whom necropsy verified the diagnosis of myocardial infarction and the second comprising 30 patients in whom a clinical diagnosis could not be verified at necropsy. In many of these patients electrocardiographic studies were made subsequent to the development of the infarcts. Analysis of these records indicates that the use of 6 precordial leads as a routine procedure appears to be of value in the accurate diagnosis of anterior myocardial infarction and represents a considerable improvement over the technic employing only a single precordial lead. When the multiple lead technic is used, errors in diagnosis will be almost exclusively those of electrocardiographic interpretation as contrasted with errors stemming from insufficient data. The use of unipolar extremity leads appears to be of comparatively little value in the diagnosis of myocardial infarction.

**Negative Results of Tocopherol Therapy in Cardiovascular Disease.**—Donegan and his collaborators attempted by laboratory tests and clinical examinations to evaluate the effect of tocopherol therapy in selected types of cardiovascular disease. The 21 patients studied included 7 with hypertensive vascular disease without cardiac enlargement, 7 patients with hypertensive vascular disease and cardiac enlargement and 7 patients with classic and relatively stable angina pectoris. The patients were seen usually at monthly intervals over periods of five to twenty months. Tocopherol therapy was found to produce no appreciable benefit either subjectively or objectively, although the blood level of tocopherol could be significantly raised by the oral administration of the drug.

**Electrocardiographic Changes in Gonococcic Arthritis and Myocarditis.**—In the 4 cases presented by Shapiro and his co-workers, the migratory polyarthritis, fever, tachycardia, electrocardiographic alterations and increase in sedimentation rate simulated the criteria proposed by Jones for acute rheumatic polyarthritis. Rheumatic fever was ruled out by the presence of a septic joint, the failure of an initial attack of arthritis to respond to salicylates in adequate dosage and/or the arrest of the septic arthritis and fever by either a sulfonamide drug or penicillin. In the first case, the septic arthritis was probably gonorrheal in origin, although results of two complement fixation tests were negative. In the other 3 cases gonococcic arthritis was diagnosed on the basis of positive cervical cultures or positive reactions to complement fixation tests, the radiologic and clinical evidence of septic arthritis and the prompt arrest of the disease by treatment with an antibiotic. The authors conclude that electrocardiographic changes and polyarthritis can no longer be accepted as pathognomonic of acute rheumatic fever, because identical electrocardiographic alterations and polyarthritis can occur in acute gonococcic arthritis. The electrocardiopathy is apparently caused by toxic gonococcic myocarditis rather than a true inflammatory lesion.

**Late Results of Thoracoplasty.**—Kinsella and his co-workers report 613 patients, 270 men and 343 women, with pulmonary tuberculosis who were subjected to extrapleural thoracoplasty at Glen Lake Sanatorium, Oak Terrace, Minn., during the period 1922-1943. Six hundred and nine of these patients had unilateral thoracoplasty carried out in 1,562 operations, while 4 had bilateral thoracoplasties performed in 12 operations, making a total of 1,574 operations for the entire series, an average of 2.6 operations per patient. Three hundred and eighty-three of the patients were operated on because of far advanced disease and 229 because of moderately advanced disease, and 1 patient had a complete thoracoplasty because of a minimal tuberculous lesion with pulmonary hemorrhage. Twenty-two of the 613 patients in the entire series died within fourteen days of the operation. A total of 34 patients died within eight weeks after operation, giving a mortality rate of 5.55 per cent based on the number of patients or 2.16 per cent based on the number of operations. The postoperative mortality rate (within eight weeks) since 1931 has been 3.0 per cent based on the number of patients and 1.16 per cent based on the number of operations. Shock, frequently of severe degree, was a very prominent feature in all of the earlier operations, but became a factor of much less importance in the latter portion of the series. Eleven of the deaths may justly be attributed to an extension of the tuberculosis. Four hundred and ten (66.8 per cent) of the entire series operated on were alive five to twenty-six years after operation and 169 (27.57 per cent) ultimately died of tuberculosis or its complications. Thirty-four patients died at various times up to eighteen years following operation from causes unrelated to tuberculosis. These survival figures clearly indicate the stability of the lesions in the patients operated on once the tuberculosis has been controlled by means of extrapleural thoracoplasty.

**Streptomycin-Tuberculosis Research Project.**—Riggins and Hinshaw report results of streptomycin therapy administered by a group of cooperating investigators in the American Trudeau Society to 332 patients, 132 men and 200 women, the majority between the ages of 20 and 39 years, who had completed streptomycin therapy and had been observed for at least ninety days after the beginning of treatment. Seventeen patients had minimal, 118 moderately advanced and 197 far advanced pulmonary tuberculosis. One hundred and seventy-seven of the 332 patients had a total of 204 known tuberculous complications, the largest number (125) with tracheobronchial and laryngeal tuberculosis. Of the 213 patients receiving daily dosages of the drug varying from 0.5 Gm. to 1.4 Gm., 148 (70 per cent) received 1.0 Gm. daily; of the 119 patients receiving daily dosages varying from 1.5 Gm. to 3.0 Gm., only 10 (8 per cent) received 3.0 Gm. daily. Clinical, roentgenologic and bacteriologic observations demonstrated that the degree of therapeutic efficacy of streptomycin is definitely related to the character of the pulmonary disease. Although improvement occurred much more frequently and was more pronounced in patients with predominantly acute disease than in those with predominantly chronic pulmonary disease, significant improvement was reported in a small percentage of patients with chronic disease. As the progression of chronic tuberculosis is fundamentally related to the occurrence of acute episodes, the great potentialities of the strategic use of short courses of streptomycin to combat such episodes should be stressed. The larger daily dosages of streptomycin appeared to bring about more frequent and more definite improvement than the smaller daily dosages, but the greater therapeutic effect was often minimized or nullified by the severer toxic manifestations incident to larger dosage. The availability of dihydrostreptomycin, which appears to be less neurotoxic than streptomycin, may aid in the solution of this problem. The occurrence of drug-fast organisms was found to be definitely related to duration of treatment. The failure to close cavities and convert sputum in a larger percentage of patients and the relapse of the disease with increasing frequency six to ten months after the beginning of treatment suggest limitations of antibacterial therapy for chronic tuberculosis and emphasize the absolute necessity of collapse therapy if lasting results are to be achieved.

Study of 120 Deaths Occurring in Dermatologic Service. P. LeVan and T. H. Sternberg.—p. 101.

**Prevention of Syphilis.**—Alexander and Schoch began in 1946 to treat persons known to have been in contact with patients who had infectious syphilis in an attempt (1) to prevent the development of the disease in these persons, (2) to reduce the spread of the disease to others and (3) to reduce the incidence of reinfection. Only persons who had had recent exposure to dark-field-positive primary or secondary syphilis and who were found to be clinically and serologically negative were included in the study. Confirmation of the exposure was ascertained by cross interrogation of the source patients and of the person suspected. The exposed persons were formed as impartially as possible into two groups. One group was treated with the abortive method; the other was kept under observation as an untreated (control) group. Each person in the treated group received an injection of 900,000 units of penicillin calcium in oil and white wax U. S. P. in one buttock, one injection of 3 cc. of bismuth ethyl-camphorate in oil in the other buttock and one of 0.05 to 0.06 Gm. of oxophenarsine hydrochloride intravenously. One hundred and forty-eight persons exposed to syphilis were given the abortive treatment. Six of these persons had early syphilis later, but 3 had definite reinfections and the other 3 were probably reinfected. Of 161 persons who had been in contact with syphilitic persons and who had not been given the abortive treatment (control group) early syphilis developed in 100, or 62.1 per cent. Thus almost two thirds of normal persons exposed to infectious early syphilis acquire early syphilis if untreated. Abortive treatment, as described, administered during the incubation stage affords almost 100 per cent protection. The authors conclude that repeated observation without treatment is not sufficient in patients who have had contact with syphilis.

**Treatment of Neurosyphilis.**—Watson reports 15 patients treated with typhoid fever vaccine and penicillin and 17 patients treated with malarial fever and penicillin. About four fifths of the patients in each group had dementia paralytica or the tabetic form of dementia paralytica, the remaining fifth having asymptomatic neurosyphilis, tabes dorsalis or meningovascular neurosyphilis. The author found that from the point of view of comfort to the patient and ease of administration, malarial fever therapy was far superior to vaccine fever therapy. In malarial fever therapy the percentage of patients who were improved was much greater, and the percentage who were worse was much less, than in vaccine fever therapy. There were fewer and less serious complications with therapeutic malaria than with vaccine fever therapy. There were no malarial relapses after the patient was treated with 3.2 Gm. of quinacrine hydrochloride over a six day period. In malarial fever therapy the laboratory tests found to be useful in judging the condition of the patient were the erythrocyte count and hemoglobin determination. A laboratory test which would aid in evaluating the condition of a patient receiving vaccine fever therapy was not found. Crystalline penicillin sodium G, 20,000,000 units given over a period of twenty-five days, seemed to be of minimal or no benefit in cases of dementia paralytica and the tabetic form of dementia paralytica. There were no deaths with either form of fever therapy.

**Streptomycin in Infections of the Respiratory Tract.**—Pulaski and White treated 44 patients, 42 adults between the ages of 17 and 51 and 2 children aged 6 and 4 years, respectively, who had nontuberculous infections of the respiratory tract, with streptomycin. Six patients with pneumonia due to Klebsiella pneumoniae (Friedländer's bacillus) were benefitted by courses of streptomycin treatment in which 0.25 to 0.4 Gm. of the drug was injected intramuscularly every three or four hours for periods of six to sixteen days. The degree of clearing of the lungs was proportionate to the duration of the infection. Two patients with pneumonia in which Hemophilus influenzae (Pfeifer's bacillus) was implicated responded rapidly to streptomycin. Results obtained in 3 cases of pulmonary tularemia confirmed the efficacy of this treatment in pleuropulmonary tularemia. In the management of coccic pneumonias, trial of streptomycin should be reserved for a final effort, to be made after penicillin or sulfonamide drugs have failed. In 2 children with pertussis and bronchopneumonia no dramatic alteration of the course of the disease attended streptomycin therapy. One patient treated with streptomycin and penicillin survived pneumonia with seven days of agranulocytosis. Streptomycin was of no value in the treatment of 1 patient with atypical pneumonia. One patient with blastomycosis, 1 with actinomycosis and 1 with moniliasis were treated with streptomycin. Sustained improvement and lasting remission were observed in the patient with blastomycosis. The patient with actinomycosis showed remission only while receiving treatment. No effect of the drug was noted in the patient with moniliasis. Streptomycin was of no value in the treatment of 6 patients with chronic bronchitis. Three patients with asthma accompanying chronic infection of the upper part of the respiratory tract, 2 patients with Hodgkin's disease, 7 patients with pulmonary sarcoidosis and 6 patients with other conditions of unknown cause were not influenced by streptomycin.

**Hemolytic Streptococcic Infections.**—Rothbard and his co-workers studied the antibody responses of 153 patients, 128 male and 25 female subjects, with 169 definite hemolytic streptococcic infections of the upper part of the respiratory tract. Fifty-four different infections were experienced by 39 patients known to have had one or more attacks of rheumatic fever previously, and 115 infections occurred among 114 nonrheumatic persons. Among the 39 known rheumatic persons there were 17 recurrences of rheumatic fever. Rheumatic fever developed in 21 of the 114 previously nonrheumatic persons. Group A streptococci caused 162 of these infections, group C caused 6 and group G caused 1. Rheumatic manifestations followed only those infections of the upper part of the respiratory tract which were due to group A hemolytic streptococci. Among these no special serologic type of Streptococcus was found associated either with rheumatic fever or with purulent complications of the original infections. None of the 7 infections due to streptococci of groups C and G led to rheumatic sequelae, although 5 of these occurred in patients who had previously had rheumatic fever. Determinations of antistreptolysin O and antifibrinolysin were done weekly for all patients; 71 patients were tested for type-specific bacteriostatic antibodies and precipitins against type-specific M, group-specific C and streptococcic nucleoprotein. Antistreptolysin O, antifibrinolysin, anti-M precipitins and type-specific bacteriostatic antibodies developed more frequently in rheumatic patients than in nonrheumatic ones. In the rheumatic group the maximal responses of antistreptolysin O and the type-specific bacteriostatic antibody were delayed about two weeks as compared to those in patients with purulent complications or who made uneventful recoveries. When the average weekly bacteriostatic antibody responses of the rheumatic and nonrheumatic groups were reviewed, the former had an average lower response than the latter during each of the second to the fifth week. At present no single pattern of antibody response can be used to diagnose the existence of rheumatic fever.

**Adrenal Cortex and Hypertension.**—Sapeika regards hypertensive vascular disease as nonrenal in origin. An attempt has been made to show that the adrenal cortex plays a major part in arterial hypertension, and much experimental and clinical data have been submitted. While there is much evidence for this point of view, final proof must still be awaited.

Tumors of Nose and Throat. G. B. New and E. L. Foss.—p. 86.

**Ménière's Symptom Complex.**—Selfridge says that the cause of Ménière's disease has been variously ascribed to disturbances of endocrine glands; infection; syphilis; low and high blood pressure; disturbances of the metabolism of salt, potassium, magnesium, iodine and calcium; deficiencies of certain vitamins (those responsible for spasm of blood vessels, as deficiency of thiamine, nicotinic acid or choline compounds); allergy; creatine-creatinine metabolism and the action of the nondecarboxylated fraction of histidine-histamine. Selfridge relates the disease to disturbances in nutrition and thus to body chemistry. He is convinced that deafness, including Ménière's disease, is not caused by any one thing but is related to all the factors involved in growth, i. e., endocrine products, electrolytes, amino acids and vitamins. He lists the principal treatments that have been advocated for Ménière's disease as follows: (1) surgical section of the labyrinthine branch of the eighth nerve; (2) treatment related to the metabolism of salt and water; (3) treatment related to the metabolism of potassium; (4) treatment related to the use of certain vitamins, especially thiamine and nicotinic acid, nicotinic acid alone, and a member of the group of choline compounds, and (5) treatment related to the use of histamine. A review of the recent literature gives the impression that the most favorable results have followed the use of several of the vitamins. Apparently surgical intervention has lost its popularity since the use of electrolytes, vitamins or endocrine substances began. Since vitamins and endocrine substances are so closely allied, as shown by their chemical formulas, it does not seem improbable that Ménière's disease is a chemical problem requiring further study and that it is related to nutritional and environmental factors.

**Local Streptomycin Therapy for Suppurative Otitis.**—Harris and his co-workers attempted to determine whether the development of resistance to streptomycin could be avoided by the local use of the antibiotic in high concentration. Bacteriologic and clinical observations were made on 27 ears with suppurative otitis receiving treatment with local instillations of streptomycin solutions. Clinical improvement occurred in about half these ears. Drainage stopped during the treatment and did not recur during a follow-up period of one to six months. Strains of organisms previously susceptible to streptomycin became resistant during the treatment in a large proportion of the cases, in spite of the fact that the concentration of the streptomycin instilled was at least twenty times as great as the minimum concentration required to inhibit the organisms isolated before treatment was started. The highly favorable results in some of the cases in which the condition had failed to improve with other forms of therapy suggest that local streptomycin therapy may be useful in suppurative otitis with organisms susceptible to streptomycin. Certain modifications which may enhance the efficacy of the therapy are suggested.

**Comparison of Penicillin and Sulfadiazine in Lobar Pneumonia.**—Volini and his associates report on a study at the Cook County Hospital in Chicago undertaken to compare the efficiency of orally and parenterally administered penicillin in pneumonia as contrasted with that of sulfadiazine and sulfadiazine combined with intramuscularly administered penicillin. Two hundred and thirty-nine patients were divided into 4 groups. Group I included 90 patients treated with sulfadiazine; group II, 54 patients treated with crystalline penicillin intramuscularly; group III, 48 patients treated with penicillin orally, and group IV, 47 patients treated with combined penicillin and sulfadiazine. The comparison demonstrates that penicillin is much superior to sulfadiazine in the treatment of pneumococcic pneumonia. In the group in which sulfadiazine was given in addition to penicillin, there was a delayed clinical response, a greater incidence of complications and a higher mortality rate. Thus the clinical use of sulfadiazine with penicillin indicates a possible antagonistic action in vivo rather than a synergistic effect. There is little justification for the combined administration of the sulfonamide drugs and penicillin in pneumonia. Penicillin alone will accomplish the desired goal if this is attainable. There are few patients with pneumonia who cannot be treated with penicillin; they may require treatment with sulfonamide drugs.

**Specificity of Histoplasmin and Coccidioidin.**—Sexton and his co-workers tested 356 natives inhabiting the Pribilof Islands in the Bering Sea, regarded as a branch of Eskimos who migrated from Alaska to the Pribilof Islands, with tuberculin, coccidioidin and histoplasmin. Eighteen white personnel who had for the most part inhabited the southwestern or Pacific Coast states or areas in which coccidioidomycosis prevails were used as controls. Severe reactions were noted in the natives after injection of the tuberculin solution. The death rate for tuberculosis in Alaska is probably the highest in the world. No native showed a reaction to coccidioidin, and only 1 native reacted to histoplasmin. Of the 18 white personnel, 3 reacted to coccidioidin and none to histoplasmin. This large series of tests indicates the consistency of negative reactions in persons who have not come in contact with the disease. The authors recognize the fact that histoplasmin must be tested further in patients known to have had or to have come in contact with the disease to establish the specificity in question.

**Eosinophilic Pleural Effusion.**—Zivitz and Oshlag report a case of pleurisy and pericarditis in a hypersensitive woman, aged 49, who had been treated for asthma with potassium iodide for five years before her admission to the hospital. The significant features were the onset with cardiac arrhythmia, pneumonitis followed by pleurisy with effusion, pericarditis with effusion, 80 per cent eosinophils in the pleural fluid, failure of reaction to penicillin and streptomycin and absence of viral causation. Recovery followed the administration of 200 to 300 mg. of tripelennamine hydrochloride (pyribenzamine®) in four doses daily for two weeks. It is not known whether the recovery was spontaneous or resulted from the use of this antihistamine drug. According to the authors this is the first attempt made with apparent success to utilize the antihistamine drugs in treatment of such a case. Even without positive pathologic observations or the reproduction of the clinical picture by a specific agent, this case illustrates the hyperergic causation of cardiovascular disease. In the absence of death with postmortem studies or in cases of localized arteritis involving organs not readily accessible for biopsy, histologic proof is impossible and reliance must be placed on clinical evaluation. Pyribenzamine® therapy did not control the allergic rhinitis and asthma, which reappeared within twenty-four hours after the patient's discharge from the hospital.

**Cephalothoracic Lipodystrophy.**—According to Barraquer Ferré progressive cephalothoracic lipodystrophy, which was first described by Barraquer Roviralta in 1906, is characterized by loss of fat tissue of the face, arms and trunk, in contrast with the normal or pathologic accumulation of fat tissue in the lower half of the body, especially on the buttocks. Progressive lipodystrophy is found much more frequently in female than in male subjects. The 10 patients observed by him were all female. He is of the opinion that the condition is caused by a central diencephalic disturbance of fat regulation. The fact that among his cases cephalothoracic lipodystrophy occurred in three generations has strengthened his conviction that, in its idiopathic form, the disease is due to hypothalamic heredodegeneration. In addition to the idiopathic, there is a symptomatic form, which may be caused by various processes, i. e., nervous, hormonal, metabolic or encephalitic. In either form the hypothalamic lesion creates a release and subsequent hyperactivity of the cervicodorsal sympathetic ganglions. Wartenberg, in his study on progressive facial hemiatrophy, assumes that this disease is caused either by heredodegeneration or other pathologic processes in the highest trophic centers, with release of lower centers, and this view reinforces the author's own with regard to cephalothoracic lipodystrophy.

**Thoracolumbar Sympathetic Block in Ureteral Colic and Calculus.**—MacLean and his co-workers report 15 cases in which they resorted to this form of treatment. Their technic of blocking the sympathetic chain is that described by Labat with a few modifications of their own. Thirteen of the 15 patients, who had a colic at the time of the administration of the sympathetic block, obtained complete relief of the colicky pain within a few minutes after the local injection of 2 per cent procaine into the thoracolumbar sympathetic chain on the affected side. Of the 15 patients who had a stone, 8 passed the calculus spontaneously, and 1 was obtained with the stone basket. Of these, 4 had previously undergone unsuccessful instrumentation. In cases of ureteral calculus in which the calculus is considered to be of a sufficiently small size to pass down the ureter, it is thought that sympathetic block may facilitate the passage of the calculus. A sympathetic block does not commit one as to what the future treatment shall be in any given case. Many of the private patients have been treated on an ambulatory basis. The sympathetic block is performed at the hospital in the morning, and then the patient goes home.

**Correlation of Clinical Aspects and Heterologous Growth in Prostatic Cancer.**—Deming shows that heterologous transplants of human prostatic cancer into guinea pigs show the same characteristics as are seen clinically. Apparently testicular androgen is necessary to initiate the growth of prostatic cancer. Prostatic cancer shows great variation in response to the female hormone. Removal of testicular androgen cannot be depended on to control prostatic cancer. Prostatic cancer in the clinical or heterologous form becomes tolerant of estrogen after varying periods of growth. This suggests that the greatest effect from its use may be expected by greater hormonal imbalance applied early in the disease. The author feels that hormonal therapy must be more efficiently applied or it must be implemented by another agent which will completely control the growth of cancer of the human prostate. There is little evidence that the control of cancer of the prostate has been improved by hormonal therapy.

**Interstitial Cystitis.**—Hand stresses the considerable number of patients with interstitial cystitis who have had concurrent gallbladder disease, motor bowel disturbance, allergies of various kinds and multiple pelvic operations. This study was undertaken to determine the incidence of these and other disease processes associated with interstitial cystitis. He presents an analysis of 223 cases (204 women and 19 men). The three arbitrary grades for evaluation of the lesions were established on the basis of the degree of bladder involvement. Thus, 138 women and 15 men had minimal, or grade 1, lesions; 37 women and 4 men had active, or grade 2, lesions, and 29 women had far advanced, or grade 3, lesions. There was no difference in the character of the disease in the two sexes, except that in none of the men did the lesions reach the far advanced stage of grade 3. Most of the minimal lesions were found in the trigone-base area, whereas the greatest number of advanced lesions either involved the whole of the bladder or were confined to the dome. One patient with interstitial cystitis had a coexisting carcinoma of the bladder. Ten other cases are cited from the literature. There was a higher incidence of allergies, gallbladder disease, cystoceles, pelvic operations and some types of foci among the patients with interstitial cystitis than among those in a group selected for comparative study. Treatment of the patients with interstitial cystitis was both general and local. Because of the high incidence of castrates among the women with interstitial cystitis (36 as against 14 in the control group), there is need for adequate management of the endocrine factor. Two women had ureteral transplantations for relief of intractable pain. One of these women also had a cystectomy. Microsections of the extirpated bladder showed capillary dilatation together with thickening of the arterioles, dilatation of the venous structures and compression of the lymph channels. The most significant observation was nerve involvement, as evidenced by edema and extensive leukocytic infiltration about and within the nerve sheaths. This microscopic evidence of nerve tissue involvement as well as some clinical observations suggest that a neurogenic factor is responsible for the beginning and the continuation of interstitial cystitis.

**Splanchnicectomy in Cerebrovascular Disease.** — Peet and Isberg say that during the ten years 1933 to 1943 more than 1,000 hypertensive patients were treated by splanchnicectomy at the University of Michigan Hospital. They cite 135 of these, who had previously sustained a cerebrovascular accident in which neurologic signs persisted for at least seventy-two hours. The five year survival rate for the series (in which male patients predominate) was 67.3 per cent, and the ten year survival rate was 40.5 per cent. The female patients had better survival rates than the male. Survival in hypertensive cerebrovascular disease is adversely influenced by the presence of retinal hemorrhages, high diastolic blood pressure and heart disease, coincidence of impaired renal function, advancing age of the patient and an interval of longer than two years between the stroke and the splanchnicectomy. Fourteen patients who had previous hypertensive cerebral accidents had normal blood pressure levels five to eleven years after operation. Approximately a third of the patients had a recurrence of cerebrovascular accident subsequent to neurosurgical treatment, and 50 per cent of the deaths were caused by such recurrences. The authors feel that as yet no definite statement can be made whether the surgical procedure of splanchnicectomy has beneficially altered the course and prolonged the lives of patients with hypertensive cerebrovascular disease. No control group is available for a proper comparison.

**Deafness Following Maternal Rubella.**—Murray discusses methods of estimating the hearing loss of preschool children whose deafness is due to maternal rubella. Reasons are given favoring the desirability of obtaining pure tone measurements. The author describes psychometric methods of obtaining the pure tone audiograms, initially by general visual and auditory cues which are later reduced to a single auditory pure tone response. Audiometric measurement was considered as giving the most reliable data with regard to the time and certainty of occurrence of maternal rubella in 105 out of approximately 350 cases. Measurements in these 105 cases (210 ears) show that the probability of hearing loss is greatest when maternal rubella occurs at about six weeks or three months of pregnancy, corresponding to the development of the cochlea and of the organ of Corti, respectively. Hearing loss is generally greatest in the low tones, decreasing on the average about 6 decibels per octave between 256 and 4,096 cycles. Deafness is moderate to severe but not total.

**Hemagglutination Test for Diagnosis of Influenzal Meningitis.**—Warburton and his co-workers describe a test for the diagnosis of influenzal meningitis which is based on the fact that the capsular polysaccharide of Hemophilus influenzae (type B) is present in the cerebrospinal fluid in sufficient concentration to inhibit agglutination by specific antiserum of erythrocytes previously sensitized with the polysaccharide. The authors describe the results of the application of this test in the laboratory diagnosis of influenzal meningitis.

**Effect of Urethane on Leukocytes in Psoriasis.**—Gilg and Perdrup of Copenhagen say that in patients with psoriasis active mitosis is found in the stratum mucosum (epidermis) and it often decreases in response to roentgen therapy of the skin. These two facts made the authors try urethane (ethyl carbamate) in the treatment of 8 patients with psoriasis. It proved to have no effect, but the authors took the opportunity to study its effect on the leukocytes of these patients, all but 1 of whom had a normal blood picture. At the onset of the treatment there was a drop in the total number of leukocytes, especially in the cases in which the number had been rather high before the treatment was started. There were no significant changes in the granulocyte-lymphocyte ratio. The existing eosinophilia likewise was not influenced.

*Menstrual Disorders in Pellagra. F. Mainzer.—p. 384.

**Vitamin D Intoxication in Case of Parathyroprival Tetany.**—Jelke reports the case of a woman, aged 54, who at the age of 35 had been operated on for goiter. She was well for the next twelve years, when tonic cramps developed in the extremities and cataract in both eyes. Hypocalcemia was observed fourteen years after the strumectomy. Treatment with A.T. 10 (dihydrotachysterol) was instituted. Three years later this drug was replaced with a synthetic vitamin $D_2$ preparation, of which 250,000 international units were taken daily for one year and three months. After this treatment had been continued for five months, hard nodes situated in the subcutaneous tissue began to appear on the arms. These corresponded to necrosis in the arterial walls and adjacent collagenic tissue. Subsequently there was increasing adynamia, dyspnea on exertion, swelling of the legs, emaciation, polydipsia and nocturia. There were signs of myocardial injury, hypercalcemia and azotemia. The nonprotein nitrogen level continued to rise steadily, at the same time as the amounts of urine diminished to the point of complete anuria. The patient died of renal insufficiency. The principal postmortem observations were renal injury with nephrosclerosis and extensive calcification of the fine interstitial arteries. The diagnosis was vitamin D intoxication with renal and vascular injuries.

**Menstrual Disorders in Pellagra.** — Mainzer cites 25 women with pellagra, 14 of whom were in the postmenopausal age and in 3 the menstrual history was unreliable, as pellagra had affected the memory. Of the remaining 8, 1 woman, with severe acute pellagra, with rapidly progressing anemia, high fever and fatal outcome, was the only patient with normal periods. The 7 other patients had menstrual disorders lasting from six months to eight years. Three of the 7 had menorrhagia, 1 had metrorrhagia and 3 had amenorrhea. Experimental and clinical observations have shown that, of the organs concerned with the sexual cycle, the function of the anterior pituitary, the adrenals and the liver is impaired by vitamin B deficiency. There is evidence strongly pointing to a pituitary origin of the amenorrhea in pellagra. Arguments are put forward supporting the view that the menorrhagia and metrorrhagia in pellagra are due to insufficient inactivation of estrogen resulting from impaired hepatic function. The adrenal and ovarian insufficiencies are assumed to be induced by a hypothetical direct influence of the deficiency state existing in pellagra. The author suggests that further studies on patients with pellagra should include biopsy of vaginal mucosa and endometrium and estimation of the urinary output of gonadotropic hormone, estrogen, 17-ketosteroids, creatinine, creatine and phosphorus.

**91**:1-130 (No. 1) 1948

Medical Viewpoints on Pathogenesis, Symptomatology and Treatment of Gallstone Disease. E. Adlercreutz.—p. 13.
Guidance in Modern Treatment with Vitamins. C. E. Nylund.—p. 28.
*Mercuric Chloride Titration of Blood Serum Especially in Diseases of Liver. R. Gordin.—p. 40.
*Hemolysis and Effect of Hemolysins in Vivo. C. Wasastjerna.—p. 48.
*Treatment of Diseases of Eye with Ultrashort Wave. Barbro Björkenheim.—p. 58.
Malignant Arrhenoblastoma. T. Brunila.—p. 66.

**Mercuric Chloride Titration of Blood Serum Especially in Diseases of Liver.**—On the basis of 221 mercuric chloride titration tests in 107 patients and of earlier investigations, Gordin concludes that this reaction is fully as reliable as the Takata reaction, with the advantage that the results are expressed numerically. The test is quickly and easily carried out. Mercuric chloride titration is primarily applicable in diseases of the liver but gives positive results also in other infections with changes in the serum proteins such as appear in disorders of the liver.

**Hemolysis and Effect of Hemolysins in Vivo.**—Wasastjerna asserts that in diseases with increased hemolysis the cause of the hemolysis may be a defect in the thrombocytes or hemolysis may depend on the presence in the blood of a substance which in some way destroys red blood corpuscles. Lysolecithin, a substance with hemolytic action, has been demonstrated in normal blood (Fahraeus). The experimental hemolysis in vivo reported by the author appears to him to be due to action of the organism on blood corpuscles which have been sensitized by small amounts of hemolysin. The spherocytosis is proportional to the hemolysis, not to the hemolysin doses, and far more pronounced in vivo than in vitro. The changes in form are also ascribed to the influence of the organism on sensitized red blood corpuscles. In this action of the organism the spleen plays an important but not dominating part. Hemolysis was more pronounced in splenectomized animals than in vitro.

**Treatment of Diseases of Eye with Ultrashort Waves.**—Björkenheim says that in 224 cases of diseases of the eye treated in the Eye Clinic of Helsingfors University from 1938 to 1946 the Siemens ultratherm apparatus was used in series of ten sessions, for ten minutes the first three times, fifteen minutes the next three times and twenty minutes the last four times, usually every other day, with wavelengths of 5 to 8 microns. The best results were attained in superficial corneal affections, iritis, postoperative iridocyclitis and neuritis. In some cases of ulcus serpens corneae, iritis, episcleritis and choroiditis, where perhaps the disease as such was not influenced, the pain disappeared. No injurious effect of the ultrashort wave was observed.

*Prescription of Rest in Bed in Infectious Diseases. J. C. de Wit. —p. 319.
Lymphatic Leukemia and Cancer. H. Deenstra, M. C. Verloop and A. de Minjer.—p. 326.

**Rest in Bed and Early Rising in Infectious Diseases.**—De Wit discusses the advisability of prescribing rest in bed for patients with internal disorders, particularly for those with febrile diseases. He investigated the incidence of thrombosis and embolism in 1,200 patients, including 300 each in four different age groups. He admits that these groups are too small to arrive at definite conclusions, but he found that in the group of patients over 60 years old, there is a high incidence of thrombosis and of lobar pneumonia and that these and other complications, such as disturbances in bowel function and in retention of urine, are reduced when rest in bed is not continued for prolonged periods. The psychic factor is important in that patients who are allowed to get up earlier usually feel better. The author allows the patient to get up frequently on the second day of an acute infectious disorder, but usually he wait until the temperature has decreased to 39 C. (102.2 F.).

allows the patient to sit up twice a day for fifteen minutes in a comfortable chair, and he advises against the use of the bed pan. On later days he lengthens the periods of sitting up. He compares a group of 1,200 patients treated in this way with the aforementioned group of 1,200. He found that early mobilization reduces considerably the number of thromboses as well as the total duration of the disease, while no disagreeable complications were observed. Early mobilization did not influence the course of the fever. The author advises closer study of the influence of early mobilization in diverse internal anomalies.

*Hormone-Producing Ovarian Tumors: Review. H. L. Kottmeier.—p. 199.
Prognosis in Acute Nephritis. J. Øster.—p. 204.
Treatment of Lesions in Brachial Plexus. G. af Björkesten.—p. 211.
*Somatic Investigations in Schizophrenics: Schizophrenia and Anorexia Nervosa. O. Lingjaerde.—p. 215.
Outcome of Routine Gynecologic Investigations in Surgical Department with Special Reference to Early Diagnosis of Cancer. W. Permin.—p. 219.
Roentgen Treatment of Hidradenitis Axillaris. N. Lauge-Hansen and S. Lyndrup.—p. 220.
Hypothalamic Lesion with Paroxysmal Crises. G. Wretmark.—p. 227.

**Hormone-Producing Ovarian Tumors: Review.**—These ovarian tumors are classified as (1) tumors causing feminine characteristics, (2) virilizing tumors and (3) other tumors with endocrine symptoms. Femininizing ovarian tumors, Kottmeier says, are granulosa cell and theca cell tumors. Granulosa cell tumors make up 4 to 9 per cent of all ovarian tumors, are usually unilateral, vary in size and occur at all ages. Before puberty they cause pubertas praecox, in the menopause, symptoms suggesting reactivation of ovarian function. The structure varies in different parts of the tumor; histologically folliculoid, cylindrotrabecular and fibrosarcomatous types appear. The tumors are often benign but may be malignant. According to present knowledge no correlation exists between histologic structure and malignity or between rapidity of growth and degree of malignity, but the sarcomatous form seems more often to be malignant. Not all granulosa cell tumors are hormone producing. Treatment is surgical; radiotherapy is indicated in cases incompletely operated on, or inoperable or with metastases. Theca cell tumors, unilateral and most frequent in the menopause, resemble granulosa cell tumors in symptoms and treatment. The first symptoms of virilizing ovarian tumors (arrhenoblastomas, adrenal rest tumors and luteinomas) are generally of defemininizing kind and followed by masculine symptoms. The tumors may be small and escape notice. With signs of virilizing ovarian tumor exploratory laparotomy is called for; if macroscopic changes are absent the adrenal region should be palpated. Arrhenoblastomas are usually unilateral, vary in size, most often occur between the ages of 20 and 40 and are histologically of highly differentiated tubular adenomatous type, solid atypical undifferentiated type or of a transition type between these forms. The more undifferentiated the tumor, the more pronounced the virile symptoms. Arrhenoblastomas are as a rule benign; cases of malignant growths have been reported. Treatment is like that of granulosa cell tumors. Tumors with thyroid tissue (struma ovarii) and the so-called gonocytomas constitute the third group.

**Somatic Investigations in Schizophrenics: Schizophrenia and Anorexia Nervosa.**—Lingjaerde says that the picture in the active phase of schizophrenia resembles that of anorexia nervosa: loss of weight, varying temperature and pulse rate curves, varying sedimentation reaction, constipation, amenorrhea, low blood pressure and low basal metabolic rate, pathologic urobilinuria and ketonuria. Necropsy reveals organic atrophy like that in long-continued inanition. The increased urobilinuria, associated with ketonuria, is primarily due to carbohydrate deficiency. Disinclination for food is characteristic of schizophrenic persons in the active phase. In anorexia nervosa this disinclination for food is a major symptom. Refusal to eat and the resulting symptoms are regarded as an important pathogenic factor at least in a large number of schizophrenic persons. The author explains the dissociation symptoms of schizophrenia as the outcome of a dynamic-energetic weakening of the ego which occurs in predisposed persons in the active phase when the ability to concentrate is weakened and consciousness is reduced. In this weakening of the ego, malnutrition and hepatic insufficiency, together with prolonged isolation, introversion, inactivity and more accidental complications of infectious or toxic kind, play an important part. The effect of malnutrition is heightened by the deficient utilization of carbohydrates.

### 79:185-212 (March 5) 1949

Psychosurgery in U. S. A. M. A. Zehnder.—p. 185.
Investigation on Cutaneous Pruritus Especially in Chronic Icterus. O. Roth.—p. 190.
*Treatment of Acute Leukemia with Exsanguination-Transfusions. G. Gottsegen and Barbara Rona.—p. 193.
New Synthetic Coagulant: Tromexan (G 11705). I. Experimental Study. R. Della Santa.—p. 195.

**Exsanguination Transfusions in Acute Leukemia.**—Gottsegen and Rona treated 1 woman aged 55 with acute myeloblast leukemia with three exsanguination transfusions at intervals of five to ten days. Ten thousand three hundred cubic centimeters of blood was withdrawn and 12,600 cc. of fresh citrated blood was infused. The general condition was slightly improved after the first exsanguination transfusion, but became gradually worse. The transfusions were well tolerated by the patient, in spite of fever and chills. The spleen increased during the treatment; the liver did not change. The number of erythrocytes was increased from 1,540,000 to a maximum of 3,060,000 in the course of the transfusion; hemoglobin rose from 21 to 49 per cent. The number of leukocytes varied from 8,000 to 12,000 before the treatment and was increased during the treatment, reaching 142,000 before death; the number of paramyeloblasts was increased from 14,600 to 130,000 per cubic millimeter. The originally large monocytoid myeloblasts were replaced more and more by micromyeloblasts. From the beginning the latter were absent from the bone marrow and no further change was observed. Death occurred on the twenty-second day after the first exsanguination transfusion. Necropsy revealed a high degree of leukemic infiltration of the inner organs.

## Wiener medizinische Wochenschrift, Vienna

### 99:85-106 (Feb. 26) 1949. Partial Index

*Etiology of Postoperative Tetanus. G. Seidl and E. Vogler.—p. 85.
Injuries of Female Genitals During Sexual Intercourse. F. Rendelstein.—p. 88.
Case of Sudden Arrest of Action of Heart Due to Embolism of Ascendant Aorta. T. Kocourek.—p. 91.

**Postoperative Tetanus.**—Seidl and Vogler report postoperative tetanus endemic from the surgical university clinic of Graz during the period of January to October 1946. Nine cases of postoperative tetanus occurred in 7 men and 2 women between the ages of 24 and 67, 7 of whom were subjected to abdominal operation in the epigastric region, 1 to inguinal herniotomy and 1 to secondary surgical intervention for a war injury of the leg. In all the cases of abdominal operation the clinical picture was characterized by doubtful prodromal symptoms followed by tenderness of the operative wound and by severe disturbances of deglutition and respiration. The toxin produced a local muscular rigidity similar to that of experimental tetanus, which was followed rapidly by generalized tetanus of ascendant type with severe respiratory spasms and choking, resulting in death within a few days. There was a constant incubation period of five to six days. All the patients died, in spite of symptomatic and specific treatment with doses up to 80,000 units of tetanus antitoxin combined with active immunization with tetanus toxoid. A virulent tetanus strain, massive infection, the localization of the point of entrance and the resulting rapid and strong effect of the toxin on the sensitive cells of the body may have been responsible for the therapeutic failures. Clostridium welchii and Clostridium tetani were demonstrated in the talc which had been used by the surgical nurses for the dusting of their rubber gloves. The sterilization of the dusted rubber gloves at a temperature of 106 C. (223 F.) for ten minutes might have been sufficient only for the destruction of Clostridium welchii but not for that of the spores of Clostridium tetani. In the case of the operated veteran the postoperative tetanus represented a fresh exacerbation of latent tetanus germs in the old gunshot wound.

# Book Notices

---

**Safeguarding Motherhood.** By Sol T. DeLee, M.D., Clinical Instructor of Obstetrics and Gynecology, University of Illinois, Chicago. Cloth. Price, $2. Pp. 135, with 43 illustrations. J. B. Lippincott Company, 227-231 S. 6th St., Philadelphia 5; Aldine House, 10-13 Bedford St., London, W.C. 2, 1949.

This small handbook for mothers is well written and beautifully illustrated; it contains a glossary of words not readily understood by a lay reader. It is designed to be a guiding and informative book for the expectant mother, carrying somewhat more information than is necessary in the average case. Concerning the complications that are discussed, the author says, reassuringly, that they usually can be prevented if the patient will follow the advice of her doctor or instructions in the book. Consequently there seems no harm in including unusual subjects, and information available about them may do some good as a warning for those who need it.

Obviously not every patient can read this or any similar book without some degree of panic over what it may suggest as possible to happen to her. That is no valid reason, however, for withholding any and all essential information from women sensible enough not to be so susceptible to suggestion. Fortunately the others are not likely to buy this or any book for study.

Physicians who practice obstetrics might read this book to their own advantage because it tells so concisely and clearly just what should be told to a patient and how.

The advice that sodium bicarbonate be used for "heartburn" might better be changed to the use of another antacid lest excessive sodium intake with its resultant effects on water retention be invited. To point out that interruption of pregnancy on account of German measles and the damage it may do to the tiny fetus is not "therapeutic abortion," according to its legal definition, is probably mere carping criticism.

The entire book is well worth while to the expectant mother, to her husband and even to her doctor.

**Clinical Orthoptics: Diagnosis and Treatment.** By Mary Everist Kramer, Supervisor, The Orthoptic Department, The George Washington University Hospital, Washington, D. C. Edited by Ernest A. W. Sheppard, M.D., Professor of Ophthalmology. The George Washington University School of Medicine, and Louisa Wells-Kramer, Certified Orthoptic Technician, Washington, D. C. Cloth. Price, $8. Pp. 475, with 147 illustrations. C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3, 1949.

This most up-to-date volume has a foreword, with current references by Dr. Sheppard. There is a preface by the orthoptist, M. E. Kramer, and in addition a page of acknowledgments. Three important references are lacking. All are of an ancient vintage although the author seems to be totally unaware of them. First is an old volume entitled "Traitement adjuvant du strabisme" by F. Terrien and A. Hubert, printed in Paris in 1902. Second is "Modern Developments in Orthoptic Training," L. L. Mayer, *Archives of Ophthalmology* 8:888, 1932, in which practically all the instruments with the possible exception of later modifications and the Worth four dot test are amply described in a review. Third is "Congenital Reading Disability-Strephosymbolia," L. L. Mayer, The Journal, April 15, 1933, page 1152, in which all previous references are acknowledged.

Over one third of the text is used to describe anatomy, the visual pathways and oculomotor system, physiology and optics. This may or may not be essential for the orthoptist but certainly enhances the value of the book. At the conclusion of each chapter are questions which are of inestimable value and also references.

An adequate index occupies the last 22 pages. This work is the latest and the best in the English literature on the subject of orthoptics. It should have a place in the library of all orthoptists and ophthalmologists. Even the child psychologist, the pediatrician and the homes of children with ocular dysfunction could benefit from its use.

**Bone Marrow Biopsy: Hæmatology in the Light of Sternal Puncture.** By S. J. Leitner, M.D., Deputy Medical Superintendent, Sanatorium for Tuberculosis, Heiligenschwendi, Berne, Switzerland. English translation revised and edited by C. J. C. Britton, M.D., Ch.B., D.P.H., Consulting Hæmatologist to the Prince of Wales's General Hospital, Tottenham, London, and E. Neumark, M.B., B.S., M.R.C.S., London. Cloth. Price, $8.50. Pp. 433, with 201 illustrations. Grune & Stratton, Inc., 381 4th Ave., New York 16, 1949.

The book is a translation of Dr. Leitner's original monograph with added references, including some to English and American authors. The original work was based mostly on the Continental literature, and most of the American references are to prewar articles, although the references to Dameshek's publications are rather extensive (18 articles). As a whole the subject matter is well presented and reflects a rich personal experience with the material. Chapters are included on technic and morphology of the bone marrow cells. The descriptions are based on cells stained by the May-Grünwald-Giemsa stain, as opposed to Wright's stain, which is more familiar to American workers. Several chapters deal with disease entities, tumors, irradiation, metabolism of the cells, tissue cultures and cultures for pathogens. The colored plates are good, as are also some of the photographs of cells. A number of points are brought out in eighty-one illustrative reports of cases. The book will be an invaluable aid to anyone who wishes a summary of European articles and observations on the bone marrow, presented in readable form.

**Symptoms in Diagnosis.** By Jonathan Campbell Meakins, C.B.E., M.D., D.Sc. Second edition. Cloth. Price, $7.50. Pp. 542, with 111 illustrations. Williams & Wilkins Company, Mt. Royal & Guilford Aves., Baltimore 2, 1948.

This book deals with the practical aspects of symptomatology, since 50 per cent of all patients do not have physical signs; it explains the symptoms in terms of pathologic physiology. The book is divided into the different systems, such as skin, skeletal and gastrointestinal. The symptoms are considered in detail under each system. The book is not intended primarily as a reference work for differential diagnosis, but it might well be used as such also. However, the book does not intend to cover the whole subject of medicine. Some of the specialties are similarly covered, and unusually well for the size of the volume.

One of the commonest causes for wrong diagnoses is the practice of "putting the patient through the work" or the "mill" and the habit of placing too much dependence on the results of the laboratory procedures. Too often there are false positive reactions to tests or inconclusive negative results or results which are irrelevant. If the patient's symptoms were better understood the physician would have more confidence in making the diagnosis to a greater degree from the symptoms and would have courage enough to have less dependence on some laboratory procedures. The book is well written and well organized.

**Film and Education: A Symposium on the Role of the Film in the Field of Education.** Edited by Godfrey M. Elliott. Cloth. Price, $7.50. Pp. 597. Philosophical Library, Inc., 15 East Fortieth St., New York 16, N. Y., 1948.

This symposium on the role of films in the field of education is comprised of 37 chapters, each prepared by a separate author. The material is divided into five major parts as follows: The Nature of the Educational Film; The Film in the Classroom; The Educational Film Outside the Classroom; The Educational Film Elsewhere, and Administrative Problems and Practices.

The purpose of the book is to present a comprehensive survey of the present and potential use of 16 mm. educational motion pictures. The chapters on "The Psychology of Showing Motion Pictures" and "Research in the Educational Film Field" will interest medical school instructors. The chapter on "Application of the Film in Health and Physical Education" is well done and should be most helpful to health educators. The author of this chapter rightfully points out that the "Health and physical education fields working as they do to develop desirable skills, habits and attitudes in their students, constitute one of the richest areas in the entire school curriculum for the successful use of educational films. No teacher—whether at the elementary, high school, or college level—can afford to overlook the enormous contribution which wise use of the film can make."

Twenty-two pages are devoted to the chapter "The Film in Medical and Nursing Education," two of which are concerned with nursing education. This chapter does not offer a great deal of useful, constructive information. It is probably the only chapter which is punctuated throughout with such phrases as "the author has been successful in starting" and "the author's contribution to this field." While several miscellaneous topics are discussed, they are not tied together in a well organized presentation.

**Das Zwischenhirn: Syndrome, Lokalisationen, Funktionen.** Von W. R. Hess, o.ö. Professor der Physiologie an der Universität Zürich. Cloth. Price, 15 Swiss francs. Pp. 187, with 82 illustrations. Benno Schwabe & Co., Klosterberg 27, Basel 10; Distributed by Grune & Stratton, Inc., 381 4th Ave., New York 16, 1949.

This book is a reprint of two extensive papers which were published in 1947 and 1948 as a supplement to the Helvetica *Physiologica et Pharmacologica Acta*. It also contains as an appendix a detailed description of the technic used in Hess' laboratory. This part is a reprint of a section of a book by the author from 1932. Since the first paper on the vegetative functions of the hypothalamus had been reviewed previously in this journal (Feb. 21, 1948, p. 587) only a note on the second paper dealing with extrapyramidal functions of the diencephalon is necessary. Stimulation of various diencephalic foci shows specific motor effects such as raising and lowering of the head, rotation of the head, contralateral movements of the foreleg and movements of the face. Coagulation of a diencephalic focus results in movements which are opposite to those seen on stimulation. These movements are interpreted as compensatory processes following stimulation of afferent (particularly vestibular) impulses. The difficult text is accompanied by many beautiful illustrations with legends in German and English.

**A History of the Heart and the Circulation.** By Fredrick A. Willius, M.D., M.S. in Med., Professor of Medicine, Mayo Foundation for Medical Education and Research, Graduate School, University of Minnesota, Minneapolis, and Thomas J. Dry, M.A., M.B., M.S. in Med., Associate Professor of Medicine, Mayo Foundation for Medical Education and Research, Graduate School, University of Minnesota. Cloth. Price, $8. Pp. 456, with illustrations. W. B. Saunders Co., 218 W. Washington Sq., Philadelphia 5, 1948.

Here is a chronologic presentation of knowledge relating to the heart and the circulation from 5000 B.C. to 1925 A.D. A second portion of the book provides biographies of many great leaders in studies of the heart and the circulation, and a third portion of the book provides a chronologic presentation of data according to such subjects as anatomy, physiology and various specific diseases. Several of the chapters and some portions of others have previously appeared in contributions to periodicals. The presentation is excellent, and the work should be a must for the library of every doctor interested in medical history and particularly for those concerned with cardiology.

**Izydor Kopernicki.** [By] Michal Ćwirko-Godycki. Poznańskie Towarzystwo Przyjaciół Nauk. Prace Komisji Lekarskiej. Tom VI. Zeszyt 2. Paper. Pp. 247. Poznańskie Towarzystwo Przyjaciół Nauk, ul. Sew. Mielzyńskiego 26/27, Posen, 1948.

The monograph by Ćwirko-Godycki presents an evaluation of the scientific work of the great Polish anthropologist Izydor Kopernicki. He was born in the province of Kiev, Russia, in 1825 and died in Cracow, Poland, in 1891. His reputation rests on his investigations of prehistoric man and his researches in morphologic anthropology. He was instrumental in introducing anthropology and he created a new anthropologic school in Poland. He had contributed much to the craniographic and craniologic studies of the prehistoric Slavs.

This monograph in Polish should prove of interest to anthropologists.

**Readings in the Clinical Method in Psychology.** Edited by Robert I. Watson, Washington University School of Medicine, St. Louis, Mo. Price, $4.50. Pp. 740. Harper & Brothers, 49 E. 33d St., New York 16, 1949.

This book is an up-to-date survey of the role of the psychologist in clinical methods. Both the diagnostic and therapeutic work of the psychologists and psychiatrist are discussed, but the emphasis is on therapy. The book is a systematic series of 50 papers by outstanding workers in the field. There are four main divisions according to subject: (1) The Clinical Method; (2) The Functions of the Clinical Psychologist; (3) Diagnostic Methods, and (4) Methods of Treatment. For each section there is a brief comprehensive review of relevant literature which is not found in the readings.

This is an excellent book for student and professional, providing recent information and valuable reference material. It discusses clinical psychology in relation to children, veterans, school systems, science, prisons and hosptials. It brings under one cover a thorough survey of the most important diagnostic methods in practice and the therapeutic method employed in clinical psychology in its various areas of work.

**Essen und Wissen: Eine praktische Ernährungskunde.** Von Hedy Bircher-Rey. Second edition. Cloth. Price, 11.50 Swiss francs. Pp. 203. Rascher & Cie. A.-G., Verlag, Zurich, 1949.

This book, for lay persons, is written by a dietitian whose doctrine constitutes a special brand of food faddism in Europe. The theory is full of misstatements and halftruths. In practice, the emphasis is on the eating of raw vegetables and the horrible things which will happen if they are not eaten. The book will not appeal to physicians.

**Social Work Year Book 1949: A Description of Organized Activities in Social Work and in Related Fields.** Editor: Margaret B. Hodges. Tenth issue. Cloth. Price, $4.50. Pp. 714. Russell Sage Foundation, 130 E. 22nd. St., New York 10, 1949.

Primarily intended for reference, this book is not detailed enough for advanced study in any field of social work.

The book is divided into two parts: Part I contains seventy-nine signed articles by authorities on civil rights, psychiatric social work and camping. Each article is a summary of the steps and general trends now in force in this aspect of social living. Part II is a directory of 546 agencies in social work related to the subject matter of part I, exclusive of profit and propagandistic groups. These are organized under four sections: International Agencies, Governmental and Voluntary National Agencies, and Canadian Agencies. In varying degrees of completeness are given the number of members, the purpose and activities and any publications issued. Topics such as medical care plans, religion and education which are closely related to social work are included.

Of invaluable aid in locating specific information is the index, which contains various cross references by functions in addition to the alphabetical subject arrangement given in the two parts.

**German-English Medical Dictionary.** Compiled by F. S. Schoenewald, M.D. Cloth. Price, 27s.6d. Pp. 241. H. K. Lewis & Co., Ltd., 136 Gower St., London, W.C. 1, 1949.

Considering the size of this dictionary, one could hardly expect it to be complete. However, there is logic in the author's contention that any word not used in the 30,000 pages of medical literature he read as a preliminary for his work is not worth listing. The one new feature that makes this dictionary especially valuable is the explanatory sentence that follows each word. This makes it easier for one to choose words with the correct shade of meaning when translating into German. Besides the purely medicotechnical terms this dictionary lists many words from the lay language which are frequently used in medical literature.

**Hormones and Behavior: A Survey of Interrelationships Between Endocrine Secretions and Patterns of Overt Response.** By Frank A. Beach, Professor of Psychology, Yale University, New Haven, Conn. With a foreword by Earl T. Engle. Cloth. Price, $6.50. Pp. 368. Paul B. Hoeber, Inc., 49 E. 33rd St., New York, 1948.

The psychosomatic approach to human activities has developed new interest in the relationships between body and mind. In those relationships activity of glands and particularly sex glands play a major part. Some of the studies recently reported by psychologists that deal with behavior of animals and men have served to advance greatly the diagnosis of disturbances of the human being from both physical and mental points of view. Especially important have been the studies of anthropoid apes. The author has consulted an enormous periodical literature in the development of this book. The conclusion is reached that in man as in animals the impact of hormonal influences on behavior is pronounced. The work establishes clearly the importance of biologic studies of all living species in understanding man.

# Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

## DANGER OF RADIATION EXPOSURE

**To the Editor:—Is there evidence that fertility, pregnancy and normalcy of offspring are deleteriously affected in physicians who are engaged in x-ray and/or radium work?**

**M.D., New York.**

ANSWER.—Small doses of roentgen rays repeated over a long period can destroy gonad function just as surely as would a few large doses. I have seen several x-ray technicians who stopped menstruating and two roentgenologists previously fertile in whom azoospermia developed. It is reasonable to suppose that dosage insufficient to produce these obvious effects might still do latent harm in the way of diminishing fertility.

Several workers now treat amenorrhea and female infertility by applying so-called stimulating doses of roentgen rays to the ovaries. So far we do not have evidence to prove that this method is harmful either to the patient or to children that she may bear later. Geneticists raise the question whether this procedure might not cause mutations in the genes of which undesirable results would appear in future generations.

Any considerable exposure to roentgen rays can seriously damage or even kill the fetus in utero. The earlier in the pregnancy, the greater the risk.

All the mentioned dangers are reduced to the vanishing point if ordinary precautions are taken. The x-ray tube should be adequately screened, and physicians and technicians should protect themselves with lead shields or aprons whenever there is the least likelihood of exposure.

Those who handle radium constantly ought to exercise similar precautions. In general with radium there is less chance than with roentgen rays that the operator's reproductive organs will be exposed.

## ENDOCRINE DWARFISM

**To the Editor:—A patient is 28 years of age, 4 feet 6 inches (137.2 cm.) tall and weighs 69½ pounds (31.4 Kg.). She does simple factory work but does not travel extensively by transit within the city limits because she feels that her appearance attracts attention. Her mother informs me that she is a high school graduate. On observing her and talking to her one wonders whether she graduated from grammar school. She rarely talks. When she does, it is usually slowly and deliberately and only for the purpose of answering simple questions. Her body and extremities seem to be fairly proportional to her height. The head and face seem to be somewhat large for the trunk and the head also appears to be somewhat retracted. The complexion is sallow and the face moderately bloated. The pulse rate is 72, the blood pressure 90 systolic and 60 diastolic, and the basal metabolic rate was estimated to be minus 35 by the Jones apparatus. She also has a moderate secondary anemia of the iron deficiency type. She has never menstruated and her mother informs me that seven years ago roentgenograms of the long bones revealed a failure of epiphysial fusion. I question whether she is a true midget or some type of endocrine dwarf. Are the basal metabolic rates of midgets the same as those of normal persons or do they show special rates? Are there characteristic roentgen findings in the bones of midgets? Is any form of endocrine therapy of value in this case?**

**Vincent D. Francis, M.D., Brooklyn.**

ANSWER.—This patient appears to have some form of endocrine dwarfism, of which there are three major classifications. In the anterior pituitary type exemplified by the Levy-Lorraine syndrome, the skeletal structure is delicate but symmetric with some delay in epiphysial fusion. The persons are alert and intelligent but somewhat infantile in personality. The dwarfism due to hypothyroidism has usually elements of myxedema or cretinism, which are readily recognized by the thick, bloated facial features, large head, short extremities and retarded mental development. They have also some gonadal deficiency. Short stature due to ovarian agenesis or failure of ovarian development is usually associated with a normal metabolic rate, frequently moderate hypertension and a delay in epiphyseal fusion often associated with osteoporosis (Wilkins, L., and Fleischmann, W.: *J. Clin. Endocrinol.* 4:357, 1944). There may be mental retardation in these cases also. The present case is not typical of any of these three types. It differs from cases of ovarian agenesis in the hypotension and low basal metabolic rate. On the other hand, there is definite evidence of a thyroid deficiency here as shown by the low metabolic rate, anemia, bone picture and even the description of sallow complexion with moderate bloating. It is possible that this is a case of pluriglandular dwarfism in which the anterior pituitary fails to secrete adequate amounts of growth, gonadotropic and thyrotropic hormones. Some authorities believe that a primary thyroid deficiency may give rise to secondary changes in the anterior pituitary. It is suggested that the blood cholesterol content be determined for confirmation of a hypothyroid state as indicated by the low basal rate. If it is found to be elevated, thyroid therapy is indicated, although it is doubted whether much growth will be obtained, because of the advanced age of the patient. Growth hormone preparations available on the market would be of little value at present. Other endocrine therapy should await the response of the patient to thyroid therapy, since it is possible, for example, that menstruation may occur if the ovarian failure is the result of hypothyroidism.

## OCCUPATIONAL OLIGOSPERMIA

**To the Editor:—Three young men, aviation crop dusters, have a severe degree of oligospermia and resultant sterility. The chemical employed for the air spraying is DDT (dichlorodiphenyltrichloroethane) in a xylene base. The men load the plane tanks by hand pump and admit that they inhale and come in close contact with the solution. Does DDT or xylene have any effect on the spermatogenic function of the testes?**

**Paul L. Singer, M.D., Phoenix, Ariz.**

ANSWER.—Neither xylene nor DDT is known specifically to impair spermatogenesis. In the presence of significant occupational diseases such as lead or carbon monoxide poisoning, depressed spermatogenesis may take place as one of several manifestations of damage but never as the sole feature. Occupational xylene poisoning is a rarity. The high boiling point of xylene (139 C.) precludes gross evaporation. While the literature is rich in references to cases of xylene poisoning, the greater number resulted from exposure to mixtures of xylene, toluene and benzene. Real exposure to xylene would have been so associated with eye, mucous membrane and skin irritation as unfailingly to have provoked medical comment.

Many toxic agents of industry have been associated with impotence. Usually such complaints are unwarranted, but oligospermia or azoospermia are objective states subject to laboratory proof. Their occurrence is sufficiently infrequent in young males that 3 closely associated men so afflicted call for further inquiry. Since carbon monoxide produces azoospermia and sterility in animals, it becomes desirable to determine the possibility of repeated low grade exposure to that gas. Control of sperm formation rests with the pituitary gland. Additional investigations should embrace that organ. Search should be made for the usual and somewhat characteristic indications of chronic xylene poisoning. These so closely resemble the well known clinical picture of benzene poisoning that that general pattern may be followed but without anticipating such findings as leukopenia or altered urinary sulfates.

The clinical data on occupational diseases are so lacking with respect to internal secretory organs that the present situation, if well confirmed and adequately explored, may provide an outstanding contribution.

## "IRREGULAR GOUT" AND DIET THERAPY

**To the Editor:—1. Is "irregular gout" (4 to 6 mg. uric acid per hundred cubic centimeters of blood) without the well known attacks a recognized entity? 2. What is the modern point of view as to the anti-uric-acid diet in cases of hyperuricemia or gout? 3. Since the methylxanthines are not supposed to appear as uric acid in the blood at all or only to a minor degree, what is the recognized point of view concerning the intake of coffee, tea, cocoa, chocolate?**

**M.D., New York.**

ANSWER.—Asymptomatic hyperuricemia is a prodromal finding in some patients in whom acute, recurrent gouty arthritis or other physical evidences of gout subsequently develop (for example, renal urate calculi or gravel, and tophi). Hench (J. A. M. A. **116**:453-459 [Feb. 8] 1941) referred to this phase as the "larval" or prearthritic stage of gout. In such instances the hyperuricemia is definite, though it often is transient and variable in intensity. The larval stage of gout is recognized and substantiated most frequently, perhaps, among the relatives of known gouty patients. The incidence of hyperuricemia among 136 blood relatives of 27 gouty patients was found to be 25 per cent (Talbott, J. H.: *Bull. New York Acad. Med.* **18**:318-328 [May] 1942).

Hyperuricemia frequently occurs in the presence of diseases other than gout, such as leukemia, polycythemia vera, psoriasis and renal failure. Obesity or a high intake of purines, or both, and laboratory errors are other circumstances in which elevation of the uric acid in the serum of whole blood may be encountered. Mild hyperuricemia is occasionally observed in patients with rheumatoid arthritis, though the explanation for this is not yet satisfactory. Hyperuricemia should not be the only, or even the principal, evidence on which a diagnosis of gout is based.

When hyperuricemia is consistently present, reduction of the intake of purines would be advisable. Glandular foods (such as liver, sweetbreads, kidneys and brain), sardines in oil, anchovies and meat extracts contain relatively large amounts of purines (160 to 825 mg. per hundred grams), but other meats such as bacon, beef, pork, veal and certain fish and fowl contain purines in amounts ranging from 75 to 150 mg. per hundred grams of the food. The quantity as well as the type of food in the patient's daily intake must be considered. Until there is a specific remedy for gout, patients so afflicted should eliminate or decrease the intake of purines as much as is necessary to help maintain adequate control of the systemic manifestations of the disease.

Methylxanthines, including coffee and other caffeine-containing beverages, theobromine and related xanthine drugs, can be used with impunity by patients with gout as these substances are not metabolized to urates (Query and Minor Notes, J. A. M. A. **137**:330 [May 15] 1948).

Urate diuretics (cinchophen, salicylates) cannot be considered as substitutes for the restriction of purines in the diet in the control of gout. However, when gout cannot be adequately controlled by dietary management alone, the supplemental use of a urate diuretic in appropriate doses may also be indicated.

---

## SEDIMENTATION RATE IN BRUCELLOSIS

*To the Editor:*—**One of our staff has made the observation that patients with brucellosis do not have an elevated sedimentation rate. Your opinion and references would be appreciated.**

**Arthur W. Allen, M.D., Ann Arbor, Mich.**

[This inquiry was referred to two authorities, whose respective replies follows.—Ed.]

Answer.—It is agreed that patients with brucellosis frequently show a normal sedimentation rate. There are exceptions, however, in cases of classic brucellosis that show an elevation of the sedimentation rate, as reported by Calder and associates (Calder, R. M.; Steen, C., and Baker, L.: Blood Studies in Brucellosis, J. A. M. A. **112**:1893 [May 13] 1939). These authors found that slow rates were common and that moderate acceleration occurred in slightly more than one third of the cases. Rapid rates were usually explained on the basis of complications such as arthritis or effusion. In a recent review of the subject by Spink (Veterans Administration Technical Bulletin, T. B. 10-49, February 28, 1949), the author states: "The erythrocyte sedimentation rate is of no diagnostic value, since either normal or accelerated values may be obtained. The sedimentation rate may be of some prognostic aid when it is rapid, in the sense that a persistently abnormal value may indicate the presence of active disease."

The sedimentation rate, when increased, is a nonspecific clinical test that is usually correlated with an increase in the concentration of the plasma fibrinogen, and occasionally the serum globulins. Fever, per se, as produced by external radiation of heat, does not produce an increase in the sedimentation rate or of the fibrinogen (Ham, T. H., and Curtis, F. C.; Plasma Fibrinogen Response in Man, *Medicine* **17**:413, 1938). It is also apparent from the clinical use of the sedimentation test that certain diseases such as many virus infections and brucellosis are conditions that are not fibrinogenic in some instances.

Answer.—The observation mentioned is in agreement with the most frequent general experience with brucellosis that the commonest clinical form, without obvious regional localizations, is usually associated with a normal sedimentation rate. Exceptions are numerous, however, not only in the presence of symptomatic or serious regional localizations but also when these cannot be detected. Harris has estimated the frequency of "abnormal rates" at about 20 per cent.

## BLOODY DISCHARGE FROM NIPPLE

*To the Editor:*—**A woman aged 53 has one child aged 13. The pregnancy and delivery were uneventful. The mother, for about four weeks, has had slight straw-colored (serosanguineous) bloody discharge of about 1 or 2 drops daily from the right nipple. The patient is otherwise in good health. Thorough and repeated examination of both breasts did not reveal perceptible evidence of any mass, tenderness or discoloration. Neither nipple is tender. The breasts are of the same size, and both nipples are normal, symmetrical in shape, location, direction and tonus. There is no distortion of nipples either singly or in comparison. Palpable nodes were not observed *in axilla, neck or sternal area.* The right nipple is slightly larger than the left but always has been so. There is not any so-called orange peel or pig skin sign in the skin about the nipple or anywhere else about the breast. The secretion has been too scanty for cytologic study. I contemplate having roentgenograms made. What more can I do to make a diagnosis of presence or absence of cancer? I would not know where to obtain a specimen for biopsy, and I still feel that I have time to search for a diagnosis before considering sending the patient to a hospital for a radical operation. She has not lost weight. Could nipple secretion at this age (patient still menstruates, but somewhat irregularly) be endocrine in nature? I consider the patient to be in the climacteric. A slight amount of the nipple secretion gave a positive reaction for hemoglobin. There is no history of local injury or trauma.**

**M.D., New Jersey.**

Answer.—Unilateral bleeding from the breast is always a problem, especially when a mass cannot be felt. In the past the danger of cancer in such a situation has been exaggerated, and we now know that only in a minority of instances is a malignant change in the breast to be feared. When the nipple is normal usually the bleeding is from intraductal hyperplasia, which tends to be multiple in location and which may not become prominent enough at any one point to produce a palpable mass. Occasionally careful milking of the breast with a finger from the periphery to the nipple will reveal which duct system is involved. This segment can then be excised. If localization is not possible, surgical exploration of the subareolar region has been recommended by Haageson. However, as the inquirer points out, where to look is a problem and a thorough exploration may yield negative results. A more feasible plan is to treat the affected breast with fractional irradiation for a total of 1,000 to 1,500 r. Such therapy usually dries the secretion and arrests the hyperplasia. Of course, periodic examination of the breast is advisable thereafter.

---

## ALOPECIA

*To the Editor:*—**Can you offer anything new in the treatment of alopecia totalis? The usual therapy has already been tried for my patient with disheartening results. My patient is a man aged 34, otherwise in excellent health but showing areas of loss of hair from the scalp, both eyebrows and eyelids, the entire face and parts of the extremities.**

**Jay Elliott Arliss, M.D., Brooklyn.**

Answer.—The duration of the alopecia is not stated, and this is an important factor in the prognosis. The longer the disorder has been present, the less likely it is to yield. The patient is arriving at an age, too, when the results from treatment become less favorable. This patient's loss of hair should not be classed as alopecia totalis, since the fall is in areas only. The presence of some hair is the bright spot in this otherwise bleak picture. Practically all local remedies may be classified as stimulants, such as cantharides, antiseptics, such as sulfur, and reducing agents, as exemplified by chrysarobin. The physical agents probably act as stimulants, too. The faradic and galvanic currents and ultraviolet rays are in this group, although the latter modality possesses oxidizing powers. I treated 2 young men with intractable alopecia areata lasting many years who subsequently got well spontaneously while in the Army during the recent war. One wonders what factor or factors were responsible for these happy results.

---

## DONOR DISQUALIFICATION

*To the Editor:*—**Should donors be rejected for any of the following reasons: (1) history of severe injury during the last war, necessitating plasma (presumably pooled) and blood (banked blood?) transfusions, either from American or German sources; (2) history of having been, during the war, in the South Pacific, Africa, Sicily or Italy; (3) history of presumably infectious hepatitis with jaundice, three years or more previously? Is there evidence that the virus of infectious hepatitis or homologous serum jaundice persists indefinitely in human beings?**

**M.D., Pennsylvania.**

Answer.—1. No. 2. No, unless there is some evidence of malaria. 3. Nothing is known about the survival in vivo of the virus of infectious hepatitis; consequently, a definite history of jaundice attributable to infectious hepatitis should permanently disqualify the donor, unless the blood is used for the production of plasma and an ultraviolet irradiation apparatus is available.

# THIOARSENITES IN AMEBIASIS

## A Clinical Appraisal of New Amebacides

HAMILTON H. ANDERSON, M.D.
HERBERT G. JOHNSTONE, Ph.D.
and
WARREN BOSTICK, M.D.
San Francisco
A. PEÑA CHEVARRÍA, M.D.
San José, Costa Rica
and
HENRY PACKER, M.D.
Memphis, Tenn.

At the beginning of World War II, a number of articles appeared on the therapy of amebiasis,[1] in anticipation of an increasing need for control. These were largely generalizations on the use of drugs introduced within the preceding ten years, notably carbarsone, vioform® (iodochlorohydroxyquinoline) and diodoquin® (diiodo-hydroxyquinoline). Nelson[1a] stated, ". . . when a number of different agents are in use in the treatment of a particular pathologic state or infection, none of the agents is completely satisfactory. In no field is this more true than in the treatment of amebiasis."

Emetine, long held by the British to be effective, either as the hydrochloride for parenteral use or as the bismuth iodide for oral administration, should not be considered a curative agent. It will control symptoms of acute dysentery and hepatitis, because it accumulates in the liver.[2] The encysted forms of Endameba histolytica are not killed by therapeutic levels of emetine in any form. Relapse is the rule rather than the exception after this drug is used alone, regardless of total amount given and duration of therapy. It is recognized that when emetine is employed patients should be hospitalized and care must be taken to avoid possible damage to cardiac muscle.

Amebiasis, as it is known in the Western hemisphere, is essentially a chronic recurrent infection which may remain dormant for years. Some agent other than emetine is required for control and complete eradication of the cysts as well as the motile forms of E. histolytica. According to Adams,[3] in his writing of British experience with the disease, this basic distinction has not been recognized generally. The common practice, in some areas, of giving periodic courses of emetine should be discouraged, because of the possibility of development of drug-resistant strains.

Historically, the halogenated hydroxyquinolines, beginning with Mühlens' and Menk's[4] introduction of chiniofon (as yatren®) in 1921, vioform® by Anderson and Koch[5] in 1931 and diodoquin® by Tenney[6] in 1936, have had considerable vogue as amebacides. Despite recent reversals of early opinions of effectiveness (D'Antoni[7]), they still are used extensively, almost always in high dosage and with other agents. The United States Navy's refusal to include diodoquin® among essential medical supplies during World War II is a reflection of the criticism being leveled against this agent. David and his co-workers,[8] in commenting on the toxic effects of diodoquin® as described by Silverman and Leslie,[9] decried the uncontrolled oral use of amebacides. Like other available agents, they are potentially toxic, and David, Phatak and Zener[8] have shown iodine levels in the blood after oral use of diodoquin.® These ranged from 45.6 to 437.25 micrograms per hundred cubic centimeters. It is not known what proportion of this is free iodide and whether diodoquin® exists as such in clinically effective amounts. Appreciable, but lower, iodine levels in the blood followed vioform® medication over a ten day period. It is possible that this compound does not break down as readily as diodoquin.®

More recently, studies of the metabolism of chiniofon, utilizing radioactive iodine, have revealed that absorption of the halogenated hydroxyquinoline also occurs. The amount was small, however, and, according to Albright, Tabern and Gordon,[10] averaged 12.9 per cent of the dose given. Absorption was prompt, the peak blood level appeared in two hours and the highest urinary level was found during the initial three hours

after ingestion. The bulk of excretion occurred by the twelfth hour, and it was complete in forty-eight hours. However, free iodide was split off from the molecule and only 7.4 per cent of the total administered chiniofon was excreted as such. The belief was expressed that blood levels of clinical importance could not be attained even with rapid absorption, because of the low percentage absorbed, the rapid urinary excretion and the body's ability to break down the drug into free iodide and organic rings.

The other chemical types most extensively used include the arsenicals, carbarsone and acetarsone. Marchoux's [11] early introduction of acetarsone (as stovarsol®) was responsible for its trial in this country. Bender [12] and others have shown frequent cutaneous and other reactions to therapeutic doses which have led to its abandonment for general use as an amebacide in the United States. Thus, carbarsone among agents in this class has enjoyed most widespread use and is considered by most authorities as a safe agent in the absence of contraindications to arsenical therapy. For the majority of patients carbarsone, alone or in combination with agents of different chemical types, is satisfactory. Experience during the recent war revealed that doses larger than originally recommended can be used even under field conditions. Hakansson anticipated this in 1938.[13]

It has been observed that, in certain patients who have been treated for relief of symptoms alone and because of inadequate follow-up, chronic resistant relapsing amebiasis has developed. In addition, there are patients who have had the disease for years, with varying degrees of invalidism, who have had no specific therapy and who present a therapeutic problem from the outset. Mackie and his co-workers,[14] in a recent survey of selected war veterans in North Carolina, has shown that among 363 persons adequately examined 40 per cent had amebiasis. He stated, ". . . almost without exception these persons were having symptoms of sufficient significance to interfere with their activity."

Palmer,[15] in an excellent follow-up study of a group of 40 veterans, said that clinical observations on wartime military amebiasis were hampered by the constant necessity for moving the patient from one area to another, with the result that final evaluation of the long range results of therapy was not possible. His report of results on conventional treatment schedules, with an average of two and a half months' observation after "cure," emphasized the tendency for remission or exacerbation to occur during observation. The persistence of colon tenderness and diarrhea, without blood, in patients not passing amebas or showing evident pathologic changes on sigmoidoscopic examination was not uncommon. Only 2 of 40 patients had spontaneous remissions and could not be found to harbor E. histolytica during the period of observation. Blunderbuss therapy of the remainder, in which a total of sixty-two courses of treatment were required, brought about some semblance of control. It was concluded that there was no apparent relationship between size of drug dose and its effectiveness in amebic colitis.

The experiences cited indicate dissatisfaction and lack of agreement regarding the therapy of amebiasis. It was for this reason that the present study was started in 1944, with the hope of developing a more effective amebacide than any now available. The results of the preliminary studies, leading to the current work with the thioarsenites, have been reported elsewhere.[16] In excess of 250 agents have been examined, representing a variety of chemical types, with in vitro and in vivo technics developed at the University of California in 1931.[17]

### EXPERIMENTAL STUDIES WITH THE THIOARSENITES

Carbarsone oxide (chemotherapy center no. 606),[18] a trivalent arsenical, identical chemically with carbarsone U. S. P. except that the arsenic has a valence of 3 rather than 5, was found to be the most active agent of a great variety tested in the laboratory. There is evidence that the reduced form of arsenic is the more active against E. histolytica, either in vitro or in vivo. Test tube comparisons of the two forms indicate at least a ten times greater direct action for carbarsone oxide. Likewise, against host tissues there is greater toxicity, and the gastric mucosa reflects this by showing hyperemia on contact with trivalent arsenic.

TABLE 1.—*Comparative Amebacidal Activities of Carbarsone Oxide and Its Dithio Derivatives in Vitro and in Vivo*

| Compound | Concentration Required in Egg Slope Medium; 48 Hours Exposure at 37 C.* | Daily Oral Dose (Mg./Kg.) Given Daily/No. Days to Clear Infected Macaques† |
|---|---|---|
| Carbarsone, U.S.P. (p-carbamidophenyl arsenic acid) | 1:2,000-1:4,000 | 30-250 over 10-23 days; partially effective in 3 of 10 animals |
| Carbarsone oxide (p-carbamidophenyl arsenous acid) | 1:40,000-1:400,000 | 11-40 over 5 to 30 days; effective in 3 of 5 animals |
| p-carbamidophenyl-bis (carboxymethylmercapto)arsine (C.C. 914) | 1:10,000-1:50,000 | 20-50 over 8 to 30 days; effective in 5 of 5 animals |
| p-carbamidophenyl-bis (2-carboxyphenylmercapto)arsine (C.C. 1037) | 1:10,000-1:50,000 | 20-50 over 8 to 30 days; effective in 5 of 5 animals |
| Emetine hydrochloride, U.S.P. | 1:10,000-1:20,000 | 3-10 over 5 to 10 days; effective in 2 of 4‡ animals |

* Anderson and Hansen,[16] and Anderson, David and Koch.[17]
† Over three month follow-up period.
‡ Toxic to cardiac muscle within the therapeutic range.

It has been shown further that the substitution of –SH groups for oxygen detoxifies arsenicals for hosts' tissue cells. By the development of two derivatives, the dithiocarboxymethyl (chemotherapy center no. 914) and the dithiocarboxyphenyl (chemotherapy center no. 1037), antiamebic activity was retained and the toxicity for host's tissues materially reduced. In table 1 are summarized the comparative in vitro and in vivo (against natural monkey amebiasis) activities.

The two thioarsenites exhibited levels of activity comparable to that of carbarsone oxide and significantly greater than that of carbarsone U. S. P. Comparative toxicity studies in mice, rats and rabbits, on oral or parenteral administration, revealed greater tolerance in "acute and chronic" dosage. There was less tissue reaction, especially when the thioarsenites were given orally. These data in the several species studied are summarized in table 2. Monkeys given 25 mg. per kilogram of body weight by mouth for thirty doses over two months exhibited no impairment of hepatic, renal or cardiac function and no evidence of damage to the skin, central nervous system or blood. At higher levels, e. g., 50 mg. per kilogram of body weight, there was, at autopsy, slight fatty infiltration of the liver and, after the dithiocarboxymethyl derivative (C. C. 914), mild albuminoid degeneration of the convoluted tubules of the kidneys. Other pharmacologic data, including distribution of arsenic throughout the tissues of rats, rabbits and monkeys, have been reported elsewhere.[19] It is of special interest that the distribution of arsenic, given in the trivalent form, differed from amounts noted after pentavalent arsenic administration, in that there were higher levels in the bile, liver, kidney, urine and intestinal tract. Appreciable tissue levels, especially in the blood, persisted in rats for at least nine days after the last dose in short term chronic toxicity tests. These observations, as well as the low levels of arsenic detected in the brain, favored consideration of the trivalent thioarsenites for application in amebiasis in human beings.

CLINICAL EVALUATION OF THE THIOARSENITES

Adequate standards of diagnosis, established by Reed and his co-workers,[20] have been adapted to the present study. Critical diagnosis was dependent on microscopic exposition of E. histolytica in iron-hematoxylin stained stool specimens. Each patient, in the current study, had three or more examinations of the stool before treatment and from six to twelve follow-up examinations over the four months after therapy was concluded. Freshly passed specimens were always requested for these examinations.

A complete history and clinical examination was obtained in each case, including proctoscopic examination whenever warranted. Laboratory studies, before as well as after therapy, included the following tests: hemoglobin (Sahli) determination, total and differential counts of white and red blood cells, urinalysis, test of hepatic function with sulfobromophthalein sodium, test of renal function with phenolsulfonphthalein and electrocardiographic tracings (in the first 50 patients treated in Memphis). Other laboratory procedures required in individual circumstances, such as roentgen examination of the lower bowel, were also repeated after therapy was concluded. An attempt was made in each case to weigh the probable influence of E. histolytica in each patient on presentation of symptoms and signs and to determine whether relief was afforded after treatment. Except in rare instances, no other antiamebic drugs were given concurrently.

For clarity, the report of the two hospital groups will be presented separately. Comparisons of the Memphis hospital patients with patients in the Hospital San Juan de Dios will be made whenever pertinent. A perusal of table 3 will indicate that there was an appreciable difference in occurrence of the pathogenic ameba (E. histolytica) in patients from the middle section of the United States and in patients from Central America. Despite the greater number of infected persons in the Costa Rican group, with higher

20. Reed, A. C.; Anderson, H. H.; David, N. A., and Leake, C. D.: Carbarsone in the Treatment of Amebiasis, J. A. M. A. **98**: 189 (Jan. 16) 1932.

frequency of symptoms and signs, it is noteworthy that trophozoites were more frequently encountered in Memphis patients. Nonpathogens were generally commoner in the former group. It should be emphasized that, in general, patients with symptoms or signs suggestive of parasitic disease of the intestines were studied in Costa Rica. This might readily account for the more than two times difference in incidence between the two groups.

The clinical status of the two groups is summarized in table 4. There were 5 children (ages 2 to 6 years) in the Memphis group, and 7 children (ages 5 to 13 years) in the Costa Rican group. Nutrition was impaired in 18 of the 47 Memphis patients, while 26 of 43 infected persons in Costa Rica were poorly nourished. There was an indication of hypoproteinemia among Costa Ricans where low hemoglobin levels were encountered. Thus, 1 had a hemoglobin level of 9 per cent, 8 between 30 and 45 per cent and 20 from 50 to 70 per cent. In contrast, only 13 Memphis patients had hemoglobin levels below 70 per cent. White cell counts above 9,000 per cubic centimeter were encountered in 15 of the 47 Memphis patients and in 14 of the 43 Costa Ricans. Red cell fluctuations were not pronounced in Memphis, but in Costa Rica there were 24 persons among the malnourished group who had counts below 4,000,000 per cubic centimeter.

* Six to 12 stool specimens examined over four or more months.

† Including 2 of 6 who vomited in each group.

‡ Including 2 not cleared with oral therapy.

§ One of 3 with hepatitis also received emetine hydrochloride, 0.5 Gm. in 5 days.

The onset of amebiasis was more acute and was apparent in a greater number of the Costa Rican patients. Diarrhea or dysentery was not significantly different in the two groups, although it was accompanied with abdominal pain and bloody stools more frequently in Costa Rica. Anorexia and nausea or vomiting occurred in 6 Costa Ricans, but concurrent disease may well have accounted for these symptoms. Likewise, hepatitis occurred in 3 and tenderness of the cecum and colon was elicited in 10 of the Central Americans.

Proctoscopic observations were compatible with the diagnosis in 21 of 26 Memphis patients and in 11 of the 13 Costa Ricans examined. These observations included ulceration, bleeding on manipulation and granulating patches in the rectosigmoid area.

Results of laboratory tests, other than those already noted, were not remarkable. The 3 Costa Rican patients with hepatitis had retention of sulfobromophthalein sodium from 5 to 20 per cent at the end of 45 minutes. Two others had low phenolsulfonphthalein excretion, 1 of 30 per cent and the other 40 per cent in 2 hours.

Of the 90 patients harboring E. histolytica, Dientameba fragilis (5 patients) and Balantidium coli (2 patients), in both hospitals, 82 were treated. Other drugs, such as diodoquin® and carbarsone, were given (by others) to 8 patients, which precluded their inclusion in our study with the thioarsenites. Among 3 of the 82 patients included, 1 each had received emetine, chiniofon or sulfadiazine prior to our examination. Table 5 summarizes the progress of therapy with the thioarsenites in the two hospital groups. The total oral dosage for adults, with each drug, in the Memphis group varied from 3.0 to 7.2 Gm. given over seven to twenty-four days. In addition, 4 patients in Memphis also received rectal instillations of C. C. 1037 in 3.0 to 6.0 Gm. amounts over six days. The Costa Rican group were given the same oral dosage throughout, for each thioarsenite, namely, 6.0 Gm. in ten days, for the adult (weighing 45 Kg. or more). Children received smaller doses based on weight. Nine Costa Rican patients with severe dysentery or hepatitis also received from 3.0 to 6.0 Gm. of C. C. 1037 by rectum during six days. The drug was not given concurrently by mouth to these patients.

Comparisons between the two thioarsenites indicated that each was *effective and there was little difference* in response to them. Thirty-three of the 38 patients given drug 914 and 41 of 44 given drug 1037 were freed of amebas. Among the 3 patients with hepatitis, 1 was given emetine hydrochloride, 0.5 Gm. parenterally in five days. This was the only other antiamebic drug administered.

In each hospital group there were 6 patients who were nauseated or vomited after the first one to three days of therapy. Phenyl salicylate coating of the 100 mg. tablets permitted completion of therapy in all but 1 patient. There were no other evidences of toxicity due to drugs, except for increased bowel movements, which did not continue after the third to fifth day of treatment. One patient, in Memphis, died of hemorrhage due to intercurrent pulmonary infection during the follow-up period. At autopsy there was no evidence of amebiasis or of toxicity due to drugs.

### RESULT OF ANTIAMEBIC THERAPY

The clinical status of the patients in the two groups improved during their stay in the hospital (Memphis summary, Anderson and his co-workers[21]). They remained only for diagnosis, drug therapy and immediate follow-up laboratory examination, because of need for their beds by others. Weight gains were encountered, particularly in the poorly nourished patients and especially in the Costa Ricans. This could be attributed to adequate diet and rest in bed and was not entirely dependent on drug therapy. Likewise, hemoglobin levels and red blood cell counts were elevated, in part because of increased protein intake. No special dietary regimen was established, however. The white blood cell counts, when elevated, were reduced to average values and in general were from 2,000 to 6,000 cells lower than at the beginning of therapy. In no patient was granulocytopenia encountered or other evidence of blood cell destruction.

---

[21] Anderson, H. H.; Johnstone, H. G.; Packer, H.; Young, J. D.; Callison, M. K.; Hambly, A. S., Jr.; Anderson, J. Van D., and Reed, R. K.: Incidence and Control of Amebiasis and Other Intestinal Protozoan Infections in a Memphis Hospital, Am. J. Trop. Med. 28: 373 (May) 1948.

In the patients with diarrhea or dysentery the number of movements was reduced to from one to three daily, except in 2 ambulatory patients who had had dysentery for more than two years. In these, bismuth subcarbonate was required to control the number and character of the movements. Proctoscopic examinations of these patients, as well as of others who exhibited changes before therapy, indicated improvement. Since the follow-up examination was made immediately after therapy and before discharge from the hospital, it was not possible to demonstrate significant changes in the appearance of the lower bowel. Certainly, there was no evidence of extension of the disease or of untoward effects of drugs on the mucosa after application of retention enemas. In cases of acute dysentery there was evidence of healing of the surface of the bowel. In such instances, where symptom relief is imperative, rectal use of thioarsenites seems effective.

Results of other tests of function of the heart, kidneys and liver were not altered by therapy. The only exceptions were in the 3 Costa Rican patients with amebic hepatitis, where the retention of sulfobromophthalein sodium at 45 minutes did not occur after thioarsenite therapy. The 2 other Costa Ricans who had low phenolsulfonphthalein excretion before treatment were within the same range on completion of therapy. Electrocardiographic changes were not encountered in any of the 50 patients who were tested. There was no alteration in urinary observations. The skin did not show evidence of untoward arsenic effects in any patient.

There was no appreciable difference in antiamebic response between the different dose levels of the two thioarsenites employed. Since the smaller dosage, 3.0 Gm. over ten days, was as effective as the largest dose, 7.2 Gm. over twenty-four days, smaller amounts will be employed in future studies. It would appear that the laboratory evidence, both in vitro and in vivo, in naturally infected monkeys was confirmed and that dose levels from one-tenth to one-fifth those required for carbarsone U. S. P. were effective in human beings. Likewise, enteric coated tablets, which permit passage of the thioarsenites through the stomach without facilitating acid hydrolysis, will provide a useful form, especially for ambulatory patients. Finally, since there was no appreciable difference in response of patients harboring motile forms or amebic cysts, it would appear that these drugs are equally effective against both. It would appear, also, that since the liver and tissues of the bowels play a large part in the distribution of the thioarsenites in the animal body, effective drug levels can be developed where needed.

### THIOARSENITES AGAINST OTHER PARASITES

During clinical trials for antiamebic response, the two thioarsenites were employed in patients harboring other parasites. The same diagnostic procedures and controls were used and the dose in each case was similar, namely, 200 mg. by mouth three times daily for ten days. Of 12 persons with Strongyloides stercoralis who were treated, the condition in only 1 was cleared. Two other Costa Ricans harboring Bal. coli, both of whom had dysentery, were cleared of this ciliate (included in tables 4 and 5). A 10 year old Costa Rican boy infected with Fasciola hepatica was not benefited by thioarsenite medication. Two others with the cutaneous lesions of Leishmania tropica and 3 other Costa Ricans with dermal manifestation of yaws due to Treponema pertenue, were not benefited by oral use of the thioarsenites. All 20 patients (14 given C. C. 914 and 6 given C. C. 1037) had post-therapy examinations of urine and blood. The results of tests of hepatic and renal function indicated no impairment. Increases in hemoglobin levels, improved nutrition and increases in body weights occurred, in part because of better care in the hospital. No evidence of toxicity due to drugs was observed.

### SUMMARY

One hundred patients harboring Endameba histolytica and other parasites in Memphis, Tenn., and San José, Costa Rica, were treated with either *p*-carbamidophenyl-bis (carboxymethylmercapto) arsine (C. C. 914) or *p*-carbamidophenyl-bis (2-carboxyphenylmercapto) arsine (C. C. 1037). These agents, in previous laboratory studies, proved approximately ten times more effective than carbarsone U. S. P. in both in vitro and in vivo tests (in naturally infected macaques).

Of 82 patients, 77 with E. histolytica, 3 with Dientameba fragilis and 2 with Balantidium coli, 74 were cleared of their parasites over a four month follow-up period. Eighteen others, infected with Dientameba fragilis (2), Strongyloides stercoralis (12), Fasciola hepatica (1), Leishmania tropica (2) and Treponema pertenue (3) had no significant benefit following thioarsenite therapy.

Complete clinical appraisal before, during and after therapy, including tests of urine, blood and hepatic, renal and heart functions, revealed no drug toxicity due to the dose levels employed (3.0 Gm. orally in ten days to 7.2 Gm. in twenty-four days). In addition, 13 of these patients with acute dysentery also received C. C. 1037 in retention enemas (3.0 to 6.0 Gm. in six days) with benefit and without evidence of drug toxicity to mucous membranes of the lower bowel as revealed by proctoscopic examination. No cutaneous reaction or damage to other tissues was observed. Twelve patients exhibited nausea or vomiting after 200 mg. doses of either thioarsenite. Coating of the tablets with phenyl salicylate permitted completion of therapy in all but 1 of these patients.

Three Costa Rican patients with hepatitis, who had evidence of sulfobromophthalein sodium retention (5 to 20 per cent) at 45 minutes (before therapy) were cleared of amebas, and their hepatic function returned to normal. One of these also required emetine hydrochloride, 0.5 Gm. given parenterally over five days. Bismuth subcarbonate was also given to 2 other patients with long-standing dysentery.

Since earlier laboratory experience was confirmed, i. e., the thioarsenites are tolerated and effective in dose levels from one-tenth to one-fifth those of carbarsone, it is suggested that enteric-coated tablets of 25 to 50 mg. be employed orally, on a three times daily dose schedule over ten days. The thioarsenites in retention enemas may also be required in patients with severe dysentery.

It would appear, on the basis of laboratory and clinical trials, that the detoxication of carbarsone oxide (*p*-carbamidophenylarsenous oxide) by substituted sulfhydril groups has permitted the use of active trivalent analogues of carbarsone U. S. P. with greater distribution of an active agent to tissues, such as the liver and intestinal tract, where amebic invasion occurs.

---

# TRAINING FOR CHILDBIRTH

HERBERT THOMS, M.D.
and
FREDERICK W. GOODRICH Jr., M.D.
New Haven, Conn.

In the foreword to Helen Heardman's recent book, "A Way to Natural Childbirth," Dr. F. J. Browne, professor of obstetrics at the University of London, writes: "Nothing has been more remarkable in the practice of obstetrics within the last ten years than the increasing appreciation of the value of principles enunciated by Edmund Jacobson in 1929 in his book 'Progressive Relaxation' and afterwards applied to midwifery by Grantly Dick Read in his two books, 'Natural Childbirth' and 'Revelations of Childbirth.'"

In considering the recommendations of those who advocate the use of procedures aimed at physiologic, or "natural," childbirth one should understand that the technics suggested are concerned with more than parturition itself. In its broad application it represents an attempt on the part of those who care for pregnant and parturient women to gain further understanding of the physiology of pregnancy and labor, including its emotional aspects, so that these functions may be viewed with better understanding and less apprehension by patients and greater skill may be developed by those who attend them.

Certain misconceptions exist which, in most instances, are concerned with pain and anesthesia, the impression being that the procedures recommended render labor painless and that anesthetics are not used. None of the proponents of these technics has suggested that labor should be conducted without anesthetic aids or that it can be made devoid of pain. In a report of 100 consecutive deliveries by Dick Read[1] in 1947, drugs and analgesia were used in 42 per cent of cases. It is our observation that with the regimen which we use the reaction to pain has been greatly lessened in most patients; however, analgesics and anesthetics are never withheld when their use is indicated, and they are usually administered whenever the patient desires them.

The effect of emotions, especially anxiety and fear, on the woman in labor has been recognized for a long time and is no recent discovery. S. C. Busey[2] in 1888 ("American System of Obstetrics") stated, "The manifestations of suffering are more influenced by mental and emotional than the physical conditions. Delicate and feeble women often pass through the travail of labor with composure and heroism, whilst the robust and healthy often exhibit their suffering in the most exaggerated manner. . . . Women in labor are very impressible and quick to observe and wrongly interpret even trivial indiscretions of word and act. The confidence of the patient in the qualifications of her attendant obviates many emotional disturbances, conduces to the harmonious succession of the physiological phenomena."

In view of the vast amount of effort expended on health education in general, it is surprising how little has been done to educate women for childbirth. Many of the books which have been written for the expectant mother are chiefly concerned with the hygiene of pregnancy and prenatal care; they do not emphasize or delineate the role of the patient as an active participant in delivery. Furthermore, but little attempt is made to allay the traditional fear with which most women approach childbirth. Helen Heardman,[3] whose personal contribution in 1947 was indispensable to the regimen now established in our clinic, in her recent book asks: "How is it that we have allowed women whose function is the reproduction of the race by muscular effort to embark upon the heavy muscular effort of labour without even a second of real training—and in FEAR?"

It is unfortunately true that many of those who attend women in childbirth tend to be preoccupied with the physical welfare of the patient and her infant, paying but little attention to the emotions of the patient, the idea being presumably that the less she knows about her own physiologic makeup the better.

## THE EDUCATIONAL PROGRAM

The important part played by emotion in increasing the sensitiveness of women to pain in labor has been emphasized by Grantly Dick Read, who points out that education of women for childbirth can serve a twofold purpose, that of allaying fear and that of preparing the patient to perform her part in the labor process.

The educational program which has been developed in our clinic is dual in its nature. First, the patient, attending small classes, is instructed in the anatomy and physiology of pregnancy and labor. Second, the patient is trained in the use of her body to aid the natural forces of labor. In this the use of certain muscle groups is learned and the art of (muscular) relaxation practiced. Women who have been educated in this manner also have aid in putting the training into practice during labor by experienced attendants who have sympathy toward the plan. This reinforcement is referred to as "support" and is given by both nurses and physicians. In England the specially trained physical therapist is used for a considerable part of such support.

Our interest in this subject began in 1947 when several patients, having read the book "Childbirth Without Fear" by Dick Read, expressed a desire to experience natural childbirth. The results obtained by most of these women were such that members of the professional and nursing staff became convinced that the subject demanded consideration. In June 1947 we began a special program of study and selected every third patient who registered in our clinic as a member of a group to which certain physiotherapeutic and educational technics were applied to supplement the usual antepartum program. Through the generosity

[3] Heardman, H.: A Way to Natural Childbirth, Baltimore, Williams & Wilkins Company, 1948.

of the Maternity Center Association of New York City, we received valuable assistance from Mrs. Helen Heardman, of England, a physical therapist who has had an extended experience working with pregnant and parturient women. Under her guidance our staff learned the exercises which are now taught in the nurses' classes for prospective mothers. The interest of the association was further shown by its generous support of three fellows, a physician and two nurses, who are now engaged in a study of the subject. Our first report appeared in November 1948[4] and dealt with our experience with 156 patients—93 primiparas and 63 multiparas. In conclusion we stated that "natural childbirth is a definite entity which can be taught successfully in a teaching ward service. We believe that natural childbirth technics offer decided advantages to mother and child, and are psychologically desirable for most women." In keeping with this latter statement it was decided on Aug. 1, 1948, to add to the routine prenatal program of all ward and staff private patients the physiotherapeutic and educational technics of the natural childbirth program.

This program at present consists of one lecture and two exercise classes given in early pregnancy and one lecture and two exercise classes given in the last half of the third trimester. At the first lecture, which is given by a physician to a group of 10 to 20 prospective mothers, the plan of education to be followed is outlined, emphasis being placed on the importance of a knowledge of the basic facts of pregnancy and labor. With the use of the Birth Atlas, anatomic charts and diagrams, the physiology and hygiene of normal pregnancy are discussed. At this time, also, the effect of anxiety and tension on physiologic functions is explained. At the conclusion of the class, which occupies forty-five minutes, questions are answered and group discussion often develops.

At the second lecture, also given by a physician when the women are four to six weeks before term, labor is discussed. The action of voluntary and involuntary muscles is explained, as are the stages of labor and the signs of beginning labor. The members of the group are told when to come to the hospital, the method of admission and the examination procedures which will follow on entrance to the ward. The patient's reaction to normal labor is discussed as well as the importance of the relaxation technics and the availability of anesthetic aids. Certain details of labor are explained, such as the purpose of rectal and vaginal examinations, artificial rupture of the membranes, episiotomy, the molding of the fetal head and the descent and propulsion of the fetus through the birth passage. The pathologic labor is not discussed except in answer to specific questions. An important purpose of the second lecture is to prepare the patient in advance so that she may know what to expect physically and emotionally, what her attendants expect her to do and how they may be expected to aid her.

The exercise classes are conducted by a nurse who is familiar with the lecture material and knows the simple exercise technics outlined in Mrs. Heardman's book. While the exercises are being taught and rehearsed, the lecture material is again presented and questions are answered. We have found that many women who may be hesitant to ask questions in the physician's classes feel more free to do so in those conducted by the nurse. A feature of the exercises is their simplicity, and this is important because the patient can fit them into her daily routine.

The exercises fall into two groups: (1) those that are aimed at increasing the tone and efficiency of the back, abdominal and perineal muscles and (2) those that promote physical relaxation, the latter finding their greatest application during labor. At the fourth and final class the procedure of admission to the hospital is again explained and the members of the group undergo a "rehearsal" of labor. At the conclusion of the class the group visits the obstetric division of the hospital. Here they meet the nursing personnel and are shown the labor and delivery rooms. They see the gas-oxygen apparatus, and use of the anesthesia mask is demonstrated.

### SUPPORT DURING LABOR

Many of our patients who have received the foregoing prenatal instructions go through a satisfactory labor with a minimum amount of support. Others may have difficulty in relaxation, may lose control and may experience a good deal of pain. Such patients, however, usually respond to the supportive technic used by the nurse or the physician. This consists in aiding the patient to put in practice the technics of relaxation that she has previously learned. It is an important part of our routine to see that no patient in active labor is left alone. Early in labor the husband or a student nurse may stay for a period with the patient.

If on admission the history and physical examination indicate that labor may be unduly prolonged, the administration of a sedative may give the patient a period of rest which will be of advantage. The relaxation technics are not instituted until the patient needs them. If relaxation becomes difficult in the first stage of labor with the cervix dilated to 4 to 6 cm., a small dose of an analgesic such as meperidine (demerol®) may be given with the suggestion that it will aid in relaxation. Our experience, which corresponds to that of others, has shown that the end of the first stage of labor is the most critical period from the standpoint of discomfort. We usually tell patients that when they pass into the second stage they will feel better. During the latter part of the first stage the lateral position which the patient has learned is often used. Massage or an icebag to the lower part of the back is helpful in relieving backache.

Bearing down efforts are not encouraged until the second stage is reached. Our experience has shown that the second stage is usually relatively rapid. During this stage gas and oxygen, self administered, are often desired. An anesthetist is present at the time of delivery for aid if a greater degree of anesthesia is desired. If episiotomy is performed, local procaine (novocain®) infiltration is used, the effect remaining during the time when suturing is done. In instances where low or outlet forceps become necessary, low spinal (saddle block) anesthesia is used because most of these patients desire to be conscious at delivery. Patients are delivered in the lithotomy position, but the legs are not placed in stirrups until the last moments.

### RESULTS

In our first report we attempted to judge our results by separating the patients into groups according to the use or nonuse of anesthetic aids during labor. Under this arbitrary plan we listed patients as excellent, good, fair or poor. The analysis showed that 126 of 156 patients, or 80.7 per cent, were in the first two categories. At present we have abandoned such rating, avoiding terms which might connote success or failure but surveying our results in monthly conferences at which both nurses and physicians attend. In a survey of our present program certain facts appear to be of interest. In the total number of deliveries (546) there were 485 anterior occiput positions, 41 occiput posteriors and 20 breech positions. The operative incidence in each category is shown in table 1.

Although it is our definite opinion that attendance at classes plays an important role in the final outcome of the labor and delivery, this is difficult to prove statistically. The classes are not compulsory, and, although all the mothers are urged to attend the classes, not all of them do so. In the 546 patients under study it was found that 109 (27.5 per cent) attended no classes whatsoever. Only 97 (17.8 per cent) attended all six classes. The rest of the patients attended varying numbers of classes. When the mother's reaction to her experience was assessed, it was found that 21.3 per cent of the mothers attending no classes had poor reactions to the delivery, while of those mothers attending all classes only 5.2 per cent had a reaction to labor and delivery which was classified as poor. The over-all rate of "failure" was 14.1 per cent. That the attention which is given the patient during labor is the most important part of the program is attested by the "success" rate in those patients who have never attended any classes. Even though a patient has not registered in a prenatal clinic and has received neither antepartum care nor instruction, she often undergoes labor and delivery with no medication, or a minimum, if she is given the proper support.

At the present writing our series consists of 546 vaginal deliveries in patients all of whom were *given* the opportunity to attend classes. We selected the first 156 patients in the series by choosing every third patient in order of registration at the clinic. The *remainder represent consecutive deliveries starting* at the time when the opportunity to attend classes was extended to all patients.

In this series the operative deliveries numbered 46 (37 primigravida, 7 multigravida), an operative incidence of 8.4 per cent. Spontaneous deliveries numbered 500 (200 primigravida, 300 multigravida). The incidence of the use of analgesia and anesthesia in these 500 spontaneous deliveries is depicted in tables 2 and 3. Table 4 shows the state of consciousness of 500 patients at delivery.

## SUMMARY

In recapitulating our experience we feel justified in making these statements:

1. An educational program incorporating physical training for prospective mothers has important advantages during pregnancy and labor.

2. Not only does a better understanding by the patient of the physiologic process of pregnancy and labor, which may be gained by instruction from physicians and nurses, reduce anxiety by increasing the confidence of the patient, but the use of physical therapy technics definitely aids in the muscular effort of labor.

3. We do not consider that the program which we have established is fundamentally new; we view it rather as an attempt to emphasize and bring into practical use certain aspects of present day knowledge of the psychology and physiology of pregnancy and childbirth.

4. Objections have been raised against such a program, to the effect that it is impractical because of the time that physicians and nurses must devote to it. We do not consider this criticism valid, because the use of the class method of instruction actually takes but little increased time. As far as attention in labor is concerned, it is our opinion that patients in active labor should not be left alone with any regimen.

5. We recognize that fear and anxiety play a large part in the creation of tension, which has undesirable effects, but we do not place undue emphasis on this aspect. We prefer to think of our program in a broad sense as being directed toward childbirth with understanding and support rather than toward childbirth without fear.

# A VENOUS SHUNT FOR ADVANCED MITRAL STENOSIS

EDWARD F. BLAND, M.D.
and
RICHARD H. SWEET, M.D.
Boston

We are recording in this report a newly devised operative procedure for the relief of acute pulmonary edema secondary to advanced mitral stenosis in which an outlet from the high pressure pulmonary area into the systemic venous bed has been created by an extracardiac shunt. This operation has now been undertaken in 5 patients. Its rationale, indications and limitations are presented herewith.

## THE PULMONARY SYNDROME OF MITRAL STENOSIS

In the evolution of rheumatic heart disease mitral stenosis ultimately develops in the majority of cases. In approximately 10 per cent a so-called "pure" form is the end result.[1] Many of these patients are able to lead comfortable and often active lives. They are frequently unaware of the cardiac abnormality until it is discovered accidentally or is revealed by characteristic complications. However, a considerable number with higher degrees of stenosis are subject to an alarming and distinctive syndrome, manifested primarily by acute pulmonary edema (fig. 1). This usually occurs at night and is often accompanied by hemoptysis. Seldom is the initial attack fatal, but recurring episodes of edema ultimately drown half the patients in this group.

This syndrome is most common in young women in the third decade. It is particularly troublesome at the time of the menses and is often brought to light by pregnancy. Infections, fever and tachycardia are poorly tolerated. Between attacks, however, these patients may be relatively well and under ordinary circumstances are remarkably free of symptoms. The heart is often only slightly enlarged in spite of tight mitral stenosis, and normal sinus rhythm is the rule.

A simple diagram illustrates the structural alterations that are present (fig. 2). Over a period of years pressure builds up in the left auricle and the pulmonary circuit behind the obstructed mitral orifice. This is reflected backward with characteristic changes in the lungs[2] and in time leads to hypertrophy of the right ventricle. Herein lies one of the ultimate difficulties: under conditions of stress, tachycardia and increased blood volume the augmented activity of the strong right ventricle floods the lungs, whose outlet is fixed by the narrowed mitral orifice. Under these circumstances pulmonary edema and hemorrhage are inevitable. Undoubtedly neurogenic and other less well understood factors influence and modify this pulmonary reaction. Nevertheless, it is an acute increment in the already excessive pulmonary pressure which is primarily responsible for this vascular crisis in the lungs. These patients succumb to pulmonary failure and not to cardiac failure. They die before their time, as far as their hearts are concerned. In fact, the heart is too good. It is therefore understandable why medical measures (digitalis, diuretics and diets), although helpful, are ultimately ineffective in dealing with this clinical paradox.

During the past fifteen years the problem presented by this group of patients has been given special consideration in connection with a long term study of rheumatic heart disease at the House of the Good Samaritan.[3] Through this period there has been no reason to be enthusiastic about a direct surgical attack on the valve itself. The experience of Cutler and associates twenty-five years ago was disappointing. Only 1 of their original 4 patients survived the procedure, and this survivor succumbed four years later with cardiac insufficiency.[4] Three subsequent attempts likewise ended fatally within a few hours of operation.[5] Sporadic interest by others in subsequent years has added little to the previously unfavorable experience. Recently and with improved technic Harken and associates[6] have had more promising results. Nevertheless, under present conditions the direct surgical approach involves a destructive procedure within the heart. It must of necessity carry a considerable risk, in addition to the debatable advantage of introducing with current technic an undesirable element of insufficiency to compensate for a predominantly stenotic valve. Furthermore, Harken noted at the time of operation an actual increase in the left auricular pressure following valvulotomy. It may be that factors other than the fenestrated valve were responsible for this undesirable increase in pressure. For the foregoing reasons and until with continuing research in that direction a more constructive type of operation in terms of valvular function becomes available, it seems best to seek relief for these patients by a less hazardous route. There are clues which suggest that help may be available outside the heart itself.

## COMPENSATORY ALTERATIONS IN MITRAL STENOSIS

In this connection a group of patients with a combination of mitral stenosis and atrial septal defect (Lutembacher's syndrome[7]) has been studied. In 1941 Bedford, Papp and Parkinson[8] recorded their observations in a similar group. These patients illustrate features which have a direct bearing on the present problem. First, even in the presence of high grade mitral stenosis they are not subject to acute pulmonary edema (or hemoptysis). The lungs are protected by the escape of blood backward through the atrial opening. This in turn places an extra burden on the right chambers of the heart in blood volume but at a lower pressure. These patients ultimately succumb to right-sided cardiac insufficiency but not to pulmonary congestion. Second, auricular fibrillation tends to occur at a later age in this group than is to be expected in patients with comparable degrees of mitral stenosis, suggesting an element of protection to the left auricle. Finally, the occurrence of mitral stenosis in such a high percentage (40 per cent) of patients wtih atrial septal defects suggests that the latter may develop from minor degrees of patency (present in perhaps 25 per cent of normal hearts) as a protective measure against the mounting pressure in the left auricle. Reasoning

along these lines, Jarotsky in 1927[9] proposed a surgically created defect as a possible solution, as did O'Farrell in 1938.[10] Recently Harken[6] has adopted their suggestion.

A further clue in a somewhat different direction is presented by the remarkably dilated bronchial veins in patients with longstanding mitral stenosis—an attempt by nature to provide an outlet from the congested pulmonary bed into the systemic veins.[11] It is of further interest that in those whose pulmonary syndrome is characterized by massive hemorrhage from these dilated varices (on occasion up to 500 cc.) the accompanying edema is often strikingly relieved or actually aborted.

Three years ago, with these facts in mind, it was decided that a vent from the high pressure area of the left auricle or adjacent pulmonary veins into a systemic vein might offer a solution to the problem. An extracardiac shunt seemed to be less hazardous than an intracardiac septal defect. Furthermore, if later the additional burden which might be placed on the right auricle and ventricle seemed excessive, the shunt could be closed with little added risk to the patient. It was finally decided that such a shunt could be created with relative ease and safety by making an anastomosis between the dorsal segment branch of the right inferior pulmonary vein and the azygos vein.

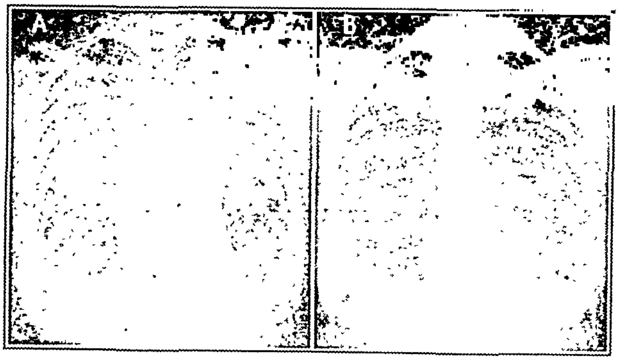

Fig. 1.—Acute and near fatal pulmonary edema in a woman aged 24, with advanced mitral stenosis but with little or no cardiac enlargement (slight fulness of the pulmonary conus and left auricle). *A*, roentgenogram on entry showing extensive edema of the lungs with characteristic butterfly distribution; *B*, roentgenogram three days later after rapid subsidence of the edema.

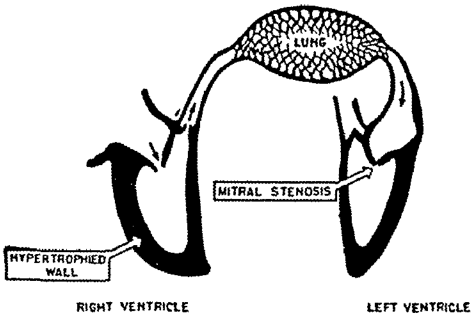

Fig. 2.—A diagram of the structural alterations responsible for the acute pulmonary syndrome (edema and hemorrhage) in patients with advanced mitral stenosis.

After two more years of deliberation and study a patient of an optimal age, under our care for nine months at the House of the Good Samaritan, was selected as a suitable candidate for the operation. It was evident that medical measures had been unsuccessful and that she was in urgent need of help in order to survive.

REPORT OF CASES

Case 1.—*History.*—Mrs. O. C. B., a Negro woman aged 17, had rheumatic fever at the age of 5 years but was well thereafter. At 14 years of age, during a routine examination, a murmur was discovered and subsequently the diagnosis of mitral stenosis was confirmed at another hospital. At the age of 15 she had the first of a series of increasingly severe attacks of pulmonary edema (cough, orthopnea, wheezing and scant blood-tinged sputum). They were most bothersome at the time of her menses. During one of these attacks she was taken to another hospital in a moribund state and spent four days in an oxygen tent. Between the acute attacks her dyspnea had slowly increased to such a degree that she curtailed her activity and gave up school. In 1947 she was admitted for study to the House of the Good Samaritan, where she had several minor episodes of pulmonary congestion in spite of a regimen that included digitalis, low sodium diet and diuretics. It was evident that her balance was precarious and her future unfavorable. Even to undertake cardiac catheterization seemed too hazardous. She was transferred in March 1948 to the Massachusetts General Hospital for surgical relief.

Her general condition was good. The heart was only slightly enlarged (fig. 3). The rhythm was regular. There were characteristic signs of extreme mitral stenosis—a loud crescendo grade 4 apical diastolic murmur ending in the shock of a loud first sound. There were no other murmurs. The pulmonary second sound was accentuated in accord with the patient's pulmonary hypertension. The blood pressure was 120 mm. of mercury systolic and 80 mm. diastolic. There was no evidence, past or present, of right-sided cardiac insufficiency. Her electrocardiogram showed slight right axis deviation. After careful preparation of the patient with a strict low sodium regimen, digitalis and diuretics, and under the protection of quinidine, an exploratory operation was performed March 23, 1948.

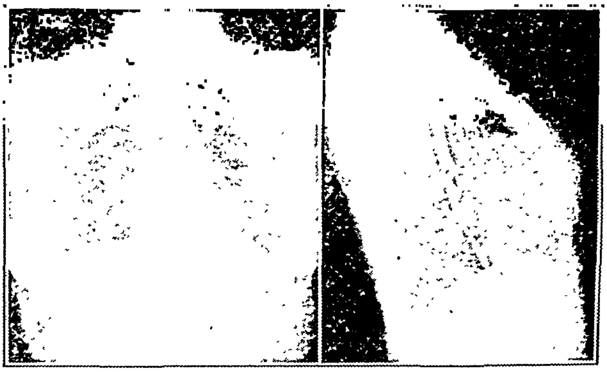

Fig. 3. (case 1).—Roentgenograms of the chest before operation. There is slight enlargement of the heart with prominence of the pulmonary conus and left auricle characteristic of mitral stenosis.

*Operation.*—A right thoracotomy incision was made intercostally through the sixth interspace. The lung was not adherent, but it presented an unusual appearance. The lung was of a peculiar dusky color and seemed to be congested and unusually firm. The inferior pulmonary vein was exposed through a short incision in the mediastinal pleura, and the dorsal segment branch was dissected out. It appeared to be unusually short, and for a brief period of time it seemed as though it could not be used. However, by dividing some of its smaller branches further into the hilum of the lung it was possible to gain about 1 cm. in length. The azygos vein was rather unusual in that it arose from the inferior portion of the chest, crossing to the left side at about the middle of the chest and then back again to the right to arch up over the

hilum and enter the superior vena cava in the normal fashion. The central portion of the azygos vein was freed and the intercostal and other small branches were ligated with fine silk. The diameter of the azygos was slightly smaller than that of the superior segment branch of the inferior pulmonary vein, but the disparity was not great.

Before the pulmonary vein was divided a pressure reading from within the left auricle was determined by means of a fine needle attached to a manometer. It was 460 mm. of water (normal, about 100 mm.). The pulmonary vein branch to be used for the anastomosis was then occluded as close as possible to its connection with the main vein, and it was cut across as far out into the pulmonary substance as possible. The distal or cardiac end which was thus secured for anastomosis was then passed over the turned-back end of the upper portion of the azygos vein, which had been cuffed back over a vitallium® (Blakemore) tube 4 mm. in diameter.[12] The two were then tied together over the tube by the usual technic, using heavy deknatel® ligatures. The occluding clamp on the azygos vein was then removed. The lung tourniquet which had been used to occlude the pulmonary vein was then taken off, and a column of blood rushed through from the high tension pulmonary vein into the azygos vein with great force. The functioning of the shunt was observed for a period of ten minutes while preparations for closing the wound were made, and at the end of that time the blood was still passing through at a rapid rate. After the lung was expanded, the chest wall was closed using pericostal sutures of surgical gut with silk for the remaining layers. A diagram (fig. 4) illustrates the anastomosis.

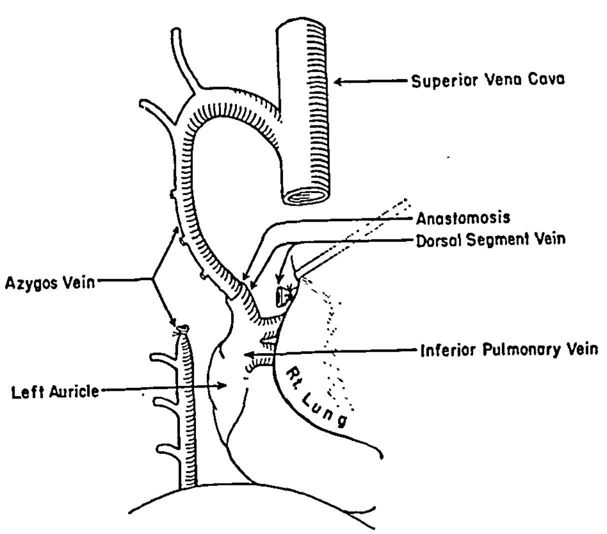

Fig. 4.—A diagram of the pulmonary-azygos shunt viewed from the right side. The lungs have been retracted forward. Oxygenated blood from the high pressure pulmonary vein—left auricle area—escapes backward through the shunt to the low pressure systemic bed distending the azygos vein throughout its course to its juncture with the superior vena cava.

*Subsequent Course.*—The patient stood the two and one-half hour procedure well. There was no pulmonary congestion (fig. 5). On the third day she was ambulatory, and on the tenth day she was presented at Medical Grand Rounds.[13] At the time of writing a year has elapsed.

On August 1948, after a moderately active summer, she entered the Emergency Ward acutely ill with severe pelvic cramps, vaginal discharge, temperature of 103 F. and tachycardia of 130. A pregnancy test was positive. With penicillin therapy the fever subsided, but because of continued cramps and vaginal discharge a dilatation and curettage was performed. Chorionic villi were identified. Sterilization was refused. She made a good recovery, and her lungs remained dry throughout this illness.

In January 1949 she was readmitted with severe nausea, vomiting, pelvic cramps and vaginal discharge. A pregnancy test was again positive. In spite of her improvement since March 1948, a dilatation and curettage again seemed best.

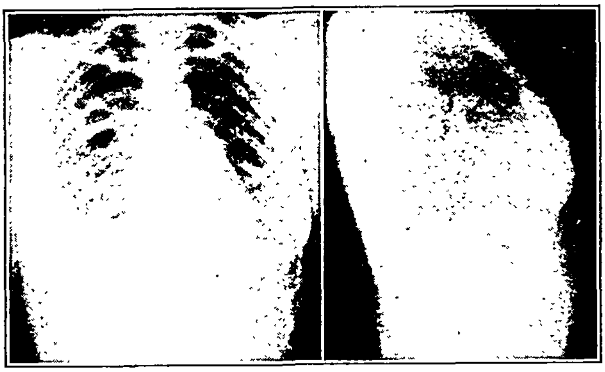

Fig. 5 (case 1).—Roentgenograms of the chest ten days after operation. The vitallium® tube at the site of anastomosis is visible behind the heart at the hilum of the right lung. The lungs are clear, but a small amount of fluid remains at the base of the right lung as a postoperative reaction. It subsided in another week.

She has been well since, but the present plan is to let the next pregnancy take its course under close supervision.

*Comment.*—During the year which has elapsed since operation this patient's course has been remarkable in that she has escaped pulmonary edema in spite of unreasonable activities, a serious infection and two pelvic operations. Considering her precarious state during the previous two years, it appears that the pulmonary-azygos shunt has protected her lungs.

Case 2.—*History.*—M. Z., a man aged 27, entered the hospital in July 1948 because of recurring pulmonary edema. Rheumatic heart disease had been discovered in a routine examination when he was 17 years of age. During subsequent years he was well and active. In 1945 he had the first of a succession of severe episodes of pulmonary congestion. During the two years before entry he had approximately twenty such attacks, characterized by acute severe dyspnea, wheezing and frothy blood-tinged sputum. The majority were precipitated by physical exertion or emotional upsets and occasionally by infection. Since January 1948 the attacks had been more frequent and on several occasions his survival seemed unlikely. In May auricular fibrillation ensued, and in spite of vigorous therapy his condition remained precarious.

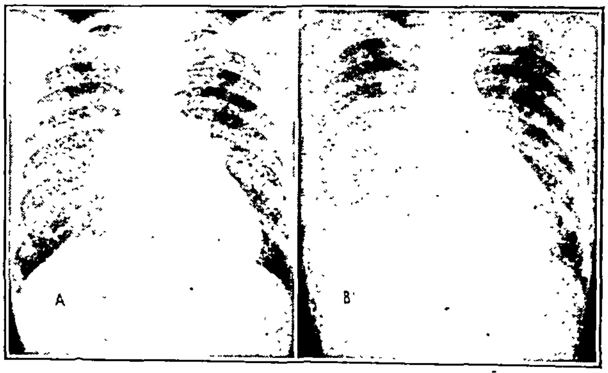

Fig. 6 (case 2).—Roentgenogram (*A*) of the chest before operation at a time when the patient was free of active congestion. The heart is considerably enlarged with prominence of the pulmonary conus and left auricle. In addition to the increased vascularity of the pulmonary roots there are miliary densities characteristic of hemosiderosis widely scattered throughout the lungs. Roentgenogram (*B*) six weeks after operation.

On entry (July 4, 1948) he was recovering from his most recent attack of acute pulmonary edema, which had occurred four days previous. There was no congestion of the cervical veins or liver and no edema. The heart was moderately enlarged (fig. 6 *A*) and absolutely irregular with an apex rate of 120. There were a well defined apical diastolic roll (grade 4) and a slapping first sound characteristic of mitral stenosis. The pulmonary second sound was decidedly accentuated, and there was a grade 2 diastolic blow along the left sternal border (slight aortic regurgitation). The blood pressure was 120 mm. of mercury systolic and 70 mm. diastolic. There were residual rales at the base of both lungs.

[13] A Venous Shunt for Marked Mitral Stenosis, Massachusetts General Hospital, Case 53, Am. Pract. **2**: 756, 1948.

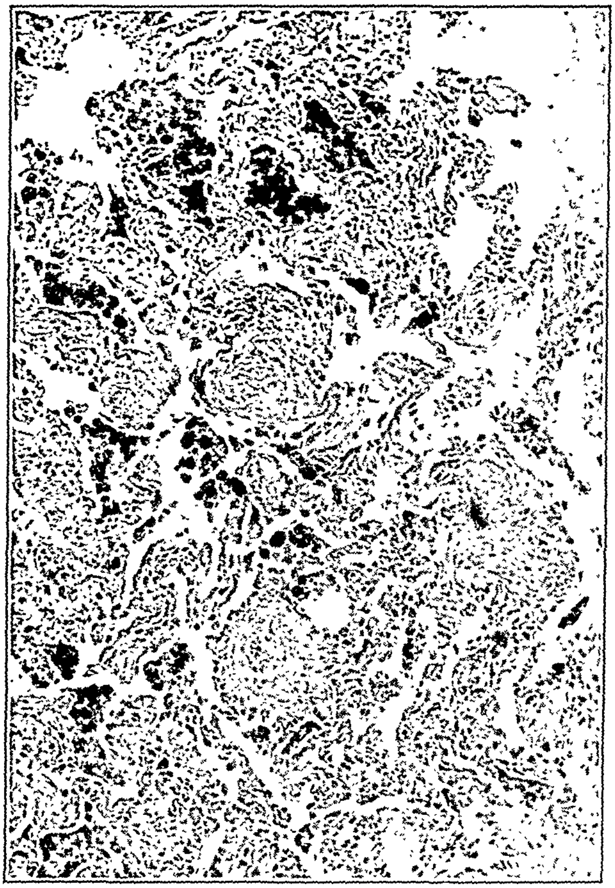

Fig. 7 (case 2).—Photomicrograph of a biopsy of the lung. The darkly stained areas are deposits of hemosiderin widely distributed throughout the section. The thickened walls of the small arteries and of the alveolar alveoli are evident. The lung is free of congestion.

He was maintained on a strict low sodium diet, digitoxin 0.3 to 0.4 mg. a day and mercurial diuretics every third day. On this regimen the apex rate receded to 80 to 90, his lungs cleared and he was again comfortable. His vital capacity was 2.8 liters. There was no clear evidence of active rheumatic fever.

In spite of these measures and without obvious cause, on July 11 he had acute pulmonary congestion, which cleared in twenty-four hours but recurred on July 15. On the evening of July 31 he again had acute severe pulmonary edema, and for the next twelve hours it seemed unlikely that he could survive. However, during the next three days his lungs cleared. There was no right-sided cardiac insufficiency. Thereafter he slowly improved, but two to three times a week he had milder episodes of nocturnal dyspnea and wheezing. His condition remained so precarious that he was unwilling to leave the hospital.

At first he was not considered as a candidate for surgical relief, chiefly because of the considerably enlarged heart and the presence of auricular fibrillation. However, it seemed evident to the family and to the consultants (Drs. Paul D. White and Samuel A. Levine) that he could not long survive these episodes of severe pulmonary congestion. In this situation the risk of operative intervention, although considerable, seemed less than that of recurring edema.

*Operation.*—On Oct. 24, 1948 the right lung was explored and the dorsal branch of the inferior pulmonary vein was anastomosed end to end with the azygos vein by means of a vitallium® tube 4 mm. in diameter. Although in this instance the azygos vein was relatively small, a good shunt was effected and a vigorous reflux of blood was observed from the tense and distended pulmonary vessel backward into the systemic vein. Direct pressure readings were not attempted in view of the precarious state of the patient.

*Subsequent Course.*—He stood the operation well but on the same afternoon had mild pulmonary congestion, which was promptly relieved by the aspiration of 800 cc. of air from the right pleural cavity. Thereafter he made a slow but satisfactory recovery. He was able to leave the hospital in a month. On Dec. 17, 1948 he returned and was shown at Medical Grand Rounds. His improvement had been remarkable in that he was leading a quietly active life which included shopping, cinema and the theater. There had been no nocturnal distress or wheezing, and he was much encouraged. In January he proceeded by train to the west coast. On Jan. 20, 1949 (three months postoperatively) Dr. W. P. Thompson in Los Angeles reported that he was in good condition and free from signs of congestion.

In February he returned east for a sojourn in Florida and subsequently journeyed to Chicago for a wedding and to Boston on March 14, 1949 for a follow-up examination. He has been entirely free of pulmonary congestion and his reserve has progressively improved. He states that on only two occasions (once in California and once in Florida) following unusual emotional excitement he had transient breathlessness for approximately ten minutes but without palpitation, cough or wheeze. The patient and his family insist that he is "75 per cent better than at any time during the past two years."

It is of interest that in this patient we suspected from the appearance of his roentgenogram (fig. 6) hemosiderosis of the lungs.[14] A small biopsy at the time of operation confirmed this suspicion (fig. 7).

*Comment.*—Surgical operation on this patient involved great risk. In the future it is unlikely that we shall attempt this surgical procedure in the presence of auricular fibrillation and cardiac enlargement of this degree, unless it is equally clear, as in this case, that recurring pulmonary edema is imminently threatening the patient's life. His improvement during the five months since operative intervention has been striking.

Case 3.—*History.*—Mrs. R. O., aged 24, had always been well, had no history of rheumatic fever or chorea and no knowledge that she had heart disease. Two years before admission (at the age of 22) when five months pregnant, she awoke at 3 o'clock in the morning with severe dyspnea and wheezing.

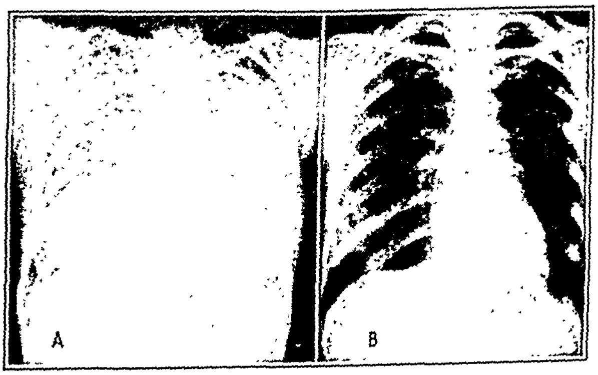

Fig. 8 (case 3).—*A*, roentgenogram during an attack of massive pulmonary edema ten months before operation; *B*, roentgenogram later, after complete recovery. In spite of tight mitral stenosis the heart is small with barely detectable alteration in contour.

---

[14] Scott, R. D. W.; Park, S. D. S., and Sandrum, A. C.: The Clinical, Radiological, and Pathological Aspects of Pulmonary Hemosiderosis, Brit. J. Radiol. **20:** 100, 1947.

She was admitted to another hospital, where she remained for eight days, with slow recovery. She was delivered at the eighth month without difficulty and was well thereafter. While in swimming sixteen months before entry, she had severe dyspnea, coughed up several ounces of blood and required morphia for relief. During mild bronchitis ten months before entry she had a third attack of acute pulmonary edema and hemoptysis and required vigorous hospital treatment with diuretics and digitalis. A roentgenogram at that time showed massive pulmonary edema (fig. 8 *A*) and a relatively small heart. Thereafter she was fairly well until two months before entry when, while walking quietly on a hot day, she again had acute pulmonary edema and hemoptysis requiring hospital treatment. In October 1948 she was referred to us by Dr. J. H. Currens for consideration of surgical relief.

On entry she was rather thin but otherwise well. The heart action was forceful with a loud (grade 4) apical diastolic murmur ending with crescendo in a slapping first sound. There was an accompanying diastolic thrill. The pulmonary second sound was definitely accentuated. The blood pressure was 105 mm. of mercury systolic and 75 mm. diastolic. The roentgenogram disclosed that the heart (fig. 8 *B*) was only slightly enlarged in the region of the left auricle and pulmonary conus. The vascular root shadows were prominent. The vital capacity was 2.5 liters. An electrocardiogram showed normal rhythm, slight right axis deviation and prominent P waves.

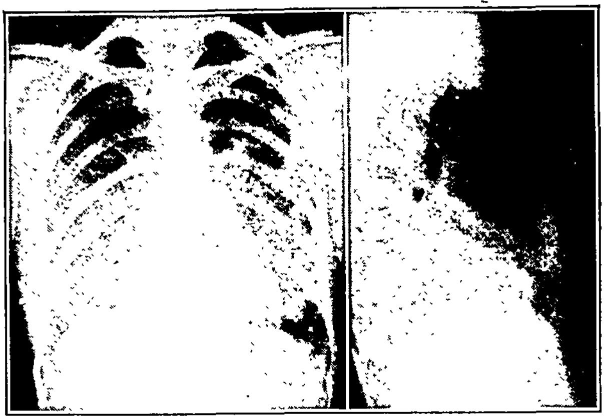

Fig. 9 (case 3).—Roentgenogram nine days after operation. The vitallium® tube is visible at the root of the right lung. Two metal clips placed at the junction of the azygos vein and superior vena cava as a guide for subsequent catheterization are faintly visible in both the anteroposterior and the lateral views.

Cardiac catheterization[15] revealed a pulmonary artery hypertension of 60 mm. of mercury systolic and 30 mm. diastolic. One minute of gentle exercise produced mild pulmonary distress and wheezing, and the pulmonary artery pressure mounted promptly to 75 mm. systolic and 36 mm. diastolic. In normal persons pressures in the pulmonary artery are approximately 25 to 28 mm. systolic and 0 to 5 mm. diastolic, and exercise is unaccompanied by a significant rise.[16]

*Operation.*—On Nov. 18, 1948 an operation was performed using a right intercostal incision. The lung presented the characteristic congested appearance of mitral stenosis. The azygos vein and dorsal segment branch of the inferior pulmonary vein were large so that an unusually satisfactory anastomosis could be made. A vitallium® tube 4 mm. in diameter was employed. After release of the clamps from the respective veins a large flow of blood could be seen and felt passing through the anastomosis into the azygos vein in the direction of the superior vena cava. A definite thrill could be felt along the azygos vein. Pressure measurements were obtained from inside the left auricle through a needle inserted at the base of the inferior pulmonary vein. The readings were 425 mm. of water with the shunt occluded and 390 mm. of water with the shunt open.

*Subsequent Course.*—The patient made an uncomplicated recovery. A chronic cough of several months' duration disappeared in three weeks. In January 1949 she returned for cardiac catheterization but was found to have a mild respiratory infection. There had been no further wheezing or hemoptysis, but further study was postponed until a later date.

Postoperative cardiac catheterization studies were made on Feb. 18, 1949. The most striking and encouraging observation in the preoperative and postoperative comparison was the ability of the patient to undergo two and one half minutes of exercise without distress with a maximal pulse rate of 95 and pulmonary artery pressures of 65 mm. of mercury systolic and 25 mm. diastolic, whereas before operation only one minute of the same exercise produced mild pulmonary congestion, with a pulse rate of 115 and pulmonary pressures of 75 mm. systolic and 36 mm. diastolic.

Studies of the oxygen content from three levels in the superior vena cava were disappointing, in that there was no significant difference as compared with preoperative determinations. Technical difficulties in obtaining well mixed samples at this level of the vascular tree are considerable. Much further study, both of pressure and oxygen content, will be necessary for objective evidence that the shunt is functioning and protecting the pulmonary circuit.

*Comment.*—In several respects this patient was considered the most suitable of the 3 because, despite definite pulmonary hypertension, her heart was small. At operation both the dorsal branch of the pulmonary vein and the azygos were large (the size of a lead pencil) and a good shunt was effected through a tube of 4 mm. bore. A prompt drop in left auricular pressure of 35 mm. of water was observed by direct measurement when the shunt was released. The entire length of azygos vein was overdistended by a forceful flow of blood sufficient to produce a thrill by direct palpation. Furthermore, studies in this case include both preoperative and postoperative catheterization of the right chambers of the heart and of the pulmonary artery. A comparison of the pulmonary pressure response to exercise before and after operation is favorable, but the oxygen content determinations are equivocal.

Case 4.—*History.*—Mrs. D. J. G., aged 42, had scarlet fever and mild arthritis at 14, but no evidence of heart disease then or during adolescence. At the age of 34, during pregnancy, she had two mild attacks of pulmonary congestion but no mention was made of her heart. At 38 years of age, after shoveling snow, she had acute pulmonary edema which lasted forty-five minutes. A physician at that time said that she had mitral stenosis. A year later (at the age of 39) she began to have recurring episodes of severe pulmonary edema, most often at the time of menses. She became increasingly dyspneic and wheezy on effort. Four months before entry she had severe pulmonary edema (with hemoptysis) for five hours and was barely rescued by vigorous hospital therapy. Three months before entry she had a similar severe attack. Two months before entry she again had pulmonary edema on two successive nights. In January 1949 she entered the hospital for a consideration of surgical relief.

She was of small stature and rather frail but otherwise well. There was no congestion. The heart was slightly enlarged, with a loud grade 4 crescendo diastolic murmur at the apex, with an accompanying thrill and with an accentuated pulmonary second sound—the characteristic observations of advanced mitral stenosis and pulmonary hypertension. In addition there was a soft grade 1 basal diastolic murmur (slight aortic regurgitation). The blood pressure was 110 mm. of mercury systolic and 70 mm. diastolic. The vital capacity was 2.2 liters. An electrocardiogram showed normal rhythm, moderate right axis deviation, and prominent P waves. A roentgenogram revealed slight cardiac enlargement (cardiothoracic ratio of 11/22 cm.), moderate prominence of the left auricle and of the pulmonary root shadows. Laboratory study and clinical observation revealed no evidence of active rheumatic infection.

---

[15] Catheter studies in this and subsequent cases were made by a cardiac catheterization team consisting of Drs. Gordon S. Myers, J. Gordon Scannell and Stanley M. Wyman.

[16] Hickam, J. B., and Cargill, W. H.: Effect of Exercise on Cardiac Output and Pulmonary Arterial Pressure in Normal Persons and in Patients with Cardiovascular Disease and Pulmonary Emphysema, J. Clin. Investigation **27**: 10, 1948.

Cardiac catheterization revealed a pressure in the right pulmonary artery of 90 mm. of mercury systolic and 50 mm. diastolic. After fifteen minutes of good relaxation the pressures slowly receded to 48 mm. systolic and 10 mm. diastolic, the pulse rate remaining at 75 during both determinations. The cardiac output was 5.26 liters per minute. After two minutes of gentle exercise, the pulse rate increased to 100 and there was a prompt and well defined increase in pulmonary pressure to 105 mm. systolic and 45 mm. diastolic.

*Operation.*—On Jan. 31, 1949 a standard thoracotomy incision was made and the right pulmonary cavity was entered through the sixth intercostal space. The lungs presented the characteristic hue and consistency of mitral stenosis. The dorsal segment vein was easily exposed and seemed longer than usual. It was exceedingly tense from obviously increased pressure. Two small branches were ligated in order to free the main stem adequately. The azygos vein was dissected free. It was found to be somewhat smaller than in the preceding 3 cases, but a satisfactory anastomosis was effected by a vitallium® tube of 3 mm. bore. On release of the clamps there was the usual rush of blood through the anastomosis, distending the azygos vein throughout its course to the vena cava. A thrill was evident by direct palpation. A pressure determination from within the left auricle was 450 mm. of water with the opened shunt. A small biopsy of the lung was made.

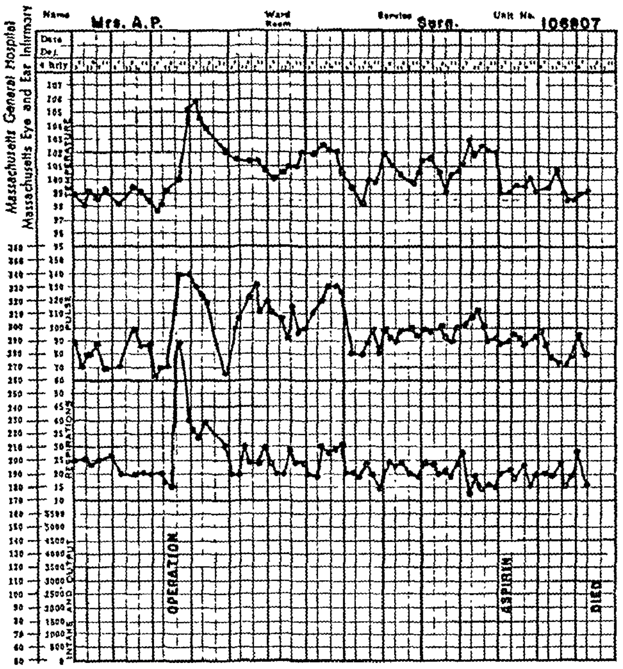

Fig. 10 (case 5).—Postoperative clinical chart showing the severe febrile reaction and subsequent course to death on the eleventh day from a recrudescence of rheumatic fever.

*Subsequent Course.*—The patient stood the two and one-half hour operation without difficulty. The lungs remained dry throughout the procedure. Two weeks later, as her activities were being increased, she had a pulmonary infarct at the base of the left lung. A bilateral superficial femoral vein ligation was performed, followed by dicumarol® therapy. She left the hospital four weeks after operation and has made a satisfactory convalescence.

*Comment.*—It is too early to appraise the results of the operative procedure in this patient. Her recovery has been slowed by the pulmonary infarct, but she weathered this complication without pulmonary edema. When she is fully stabilized, it is planned to study her further by cardiac catheterization.

Case 5.—*History.*—Mrs. A. P., aged 30, had chorea at the age of 12 years but without evident cardiac involvement. At the age of 15 an apical diastolic murmur was noted, but she continued active and free of symptoms. At the age of 25, during pregnancy, she had severe dyspnea and frequent hemoptysis. Her symptoms became so alarming that she was delivered in the sixth month by cesarean section at the Boston Lying-In Hospital. The child did not survive. At 26 years of age she had acute pulmonary edema after mounting one flight of stairs. Thereafter she had frequent minor spells of acute dyspnea, coughing and blood-tinged sputum on slight effort or excitement. Since then her activities had been appreciably limited in spite of digitalis, diuretics and a restricted salt diet; mounting three to four steps would cause minor pulmonary congestion. Because of her precarious state she was referred to the hospital for a consideration of surgical relief.

On entry she appeared in fair health. There was no congestion of the cervical veins, lungs or liver, and no edema. The heart was moderately enlarged, with the characteristic signs of advanced mitral stenosis and a loud pulmonary second sound. The blood pressure was 120 mm. of mercury systolic and 65 mm. diastolic. The vital capacity was 1.8 liters. The electrocardiogram showed normal rhythm, right axis deviation and prominent P waves. Roentgen examination confirmed the presence of moderate cardiac enlargement, chiefly in the region of the left auricle, and accentuated hilar vascular markings.

Laboratory studies revealed two factors suggestive of smouldering rheumatic activity; namely, a leukocytosis of 12 to 14 thousand and a corrected sedimentation rate of 1.2 mm. per minute. A venous pressure determination was normal.

Cardiac catheterization revealed extreme pulmonary hypertension actually in excess of the systemic blood pressure, namely, 130 mm. of mercury systolic and 40 mm. diastolic in the right pulmonary artery. Gentle exercise resulted in a prompt increase in pulmonary artery pressure to 145 mm. systolic and 65 mm. diastolic. The cardiac output was 4.6 liters per minute at rest and 4.2 liters per minute with exercise.

In view of the recurring pulmonary congestion and the extreme pulmonary hypertension, operation was undertaken in spite of the suspicious signs of rheumatic activity. In retrospect, more attention should have been directed to the latter feature.

*Operation.*—On Feb. 7, 1949 the chest was entered through the right sixth intercostal space. Unlike the previous cases, considerable difficulty from pulmonary congestion was encountered throughout the operation and the air passages required frequent clearing by suction. However, an excellent anastomosis was effected in the usual manner, employing a vitallium® tube 4 mm. in diameter. Direct measurement of the left intra-auricular pressure was 530 mm. of water, and after the shunt was released the pressure dropped to 370 mm. As usual, the azygos vein was greatly distended by the forceful reflux of blood, and a distinct thrill was evident by palpation.

*Subsequent Course.*—From onset the postoperative course was hectic and totally unlike that of any of the preceding 4 patients (fig. 10). There was an immediate and pronounced febrile reaction to 106 F. (by rectum), followed by a persistent fever, the cause of which was not evident until the eighth day when, by exclusion, rheumatic fever was suspected. On administration of acetylsalicylic acid there was a prompt response, but the patient continued to decline, with scant urinary output, mounting nonprotein nitrogen and a terminal paroxysm of auricular fibrillation followed by death on the eleventh postoperative day.

*Necropsy.*—Postmortem examination revealed moderate congestion of the lungs and liver, and a pulmonary infarct. The heart weighed 450 Gm. There was well defined hypertrophy of the right ventricle. The mitral valve was seen to be stenosed and rigid, barely admitting the tip of a small finger. Along the closure line on the aortic and tricuspid valves were rows of minute (2 mm.) fresh pinkish vegetations characteristic of acute rheumatic valvulitis. Sections of the myocardium exhibited focal areas of perivascular infiltration, including many eosinophils.

The site of the anastomosis was of particular interest. There was no unusual external reaction. However, it was occluded by a relatively fresh antemortem thrombus nonadherent to the walls and by section estimated to be at most a few days old. The structure of the red cells remained distinct. From the postmortem appearance it seemed likely that the shunt had functioned satisfactorily during at least the first postoperative week, in spite of the patient's serious state, but had become occluded during the terminal days of illness.

*Comment.*—In retrospect it was a mistake to undertake operative intervention at the time, in the presence of nebulous but nonetheless suspicious signs of rheumatic activity. A severe reactivation of rheumatic fever was in large measure responsible for this patient's hectic course and ultimate death eleven days after operation. This unpredictable reaction of rheumatic persons to physical trauma, commented on in the past,[17] will continue a potential risk in future cases, but the fatal outcome in this patient emphasizes the necessity for a careful search for signs of smouldering rheumatic activity in future candidates for this and similar surgical procedures.

### CONCLUDING REMARKS

The clinical improvement in the first 3 patients during twelve, five and four months, respectively, subsequent to operation has been remarkable. None has had pulmonary edema. Their exertional dyspnea and palpitation have lessened. Direct measurement of the left auricular pressure at the time of operation confirmed clinical and catheter studies indicative of extreme pulmonary hypertension four to five times the normal range. Collateral determinations under similar conditions in patients with normal hearts have revealed left auricular pressures of approximately 100 mm. of water.

It has been demonstrated at operation that a significant lessening of left intra-auricular pressure follows release of the shunt. On the other hand, in no instance has there been clinical evidence that this reduction in left auricular pressure was sufficient to impair the peripheral circulation. (There was a suspicion of this in case 5, but other factors dominated the picture.) Nevertheless, too large a shunt is undesirable, too small a shunt may ultimately occlude. It is hoped that the one under consideration may avoid both extremes.

No significant murmur attributable to the shunt has been audible on closure of the chest, even at the time one can be certain the anastomosis is fully patent. Perhaps the high pressure gradient and sustained flow through the shunt preclude a murmur.

Further study and experience are essential to determine whether or not the present shunt is adequate. It may be that a direct anastomosis without the intermediate vitallium® tube will be preferable, or the use of larger vessels may be required. However, in these early cases the simplest method and the smallest shunt that offered promise seemed preferable.

### SUMMARY

A newly devised operative procedure for the relief of recurring pulmonary edema secondary to advanced mitral stenosis is presented. It consists of an extracardiac shunt to provide an outlet from the high pressure left auricle–pulmonary vein area into the systemic venous bed. This is accomplished by anastomosing the dorsal segment branch of the right inferior pulmonary vein to the azygos vein.

The procedure has been undertaken in 5 patients during the past year. The subsequent improvement in the first 3 has been remarkable. Insufficient time has elapsed (two months) in case 4 to warrant conclusions, but progress to date has been satisfactory. The fifth patient succumbed on the eleventh postoperative day to a severe recrudescence of rheumatic fever.

Direct measurements of pressure in the left auricle at operation confirm clinical and catheter studies indicative of extreme pulmonary hypertension. A significant reduction in this pressure on release of the shunt has been measured. It is hoped that its dampening effect will be adequate to protect these patients from acute vascular crises within the lungs. The rationale, indications and limitations of this procedure are discussed.

The present report is preliminary, and further study of technics and results are essential for final appraisal. It is to be emphasized that this is not a procedure to be undertaken for patients with large weak hearts: it is designed for those with small strong hearts as a protection to the lungs. It is a compromise and not a cure.

# CONTRACEPTION AMONG TWO THOUSAND PRIVATE OBSTETRIC PATIENTS

ALAN F. GUTTMACHER, M.D.
CHRISTOPHER TIETZE, M.D.
and
SAMUEL RUBIN, M.D.
Baltimore

There are many unknowns in any formula describing the sexual conduct of the American people. Some of these have been partially solved through the efforts of the amazing Dr. Kinsey. Not only has Dr. Kinsey produced facts but, far more important, he has stressed principles. The foremost, that one cannot make generalizations which apply to the sexual practices of the American. In matters of sex there is no typical Mr. or Mrs. America, for our sexual mores are stratified, each layer largely determined by educational background and economic status.

It therefore becomes important in establishing the status of modern contraception to inquire into the conceptional and anticonceptional histories and practices of all types of people, under all conditions, from all walks of life and from all parts of the country. Most of the studies previously reported have been based on specialized groups under specialized conditions—namely, contraceptive clinic patients who are not pregnant and are urgently desirous of remaining not pregnant. In most instances they seek help because they are harassed by too much fertility and too little money. There have been but few surveys of the private patient group.[1] Then too, there are surprisingly few contraceptive studies on the pregnant woman; especially the woman who has just achieved pregnancy voluntarily or involuntarily.

### CLINICAL MATERIAL AND METHOD

The present survey is therefore unusual, for it deals with the contraceptive history and practices of 2,000 private obstetric patients. During the past several years one of us (A. F. G.) obtained from all patients who came to register for prenatal care and delivery, in

A. **110**:1169-1172 (April 9) 1938; Contraception and Planned Parenthood in Private Practice, Human Fertil. **5**: 76-80 (June) 1940. Warner, M. P.: Contraception: A Study of Five Hundred Cases from Private Practice, J. A. M. A. **115**: 279-285 (July 27) 1940.

addition to the ordinary obstetric history, answers to four questions, the questions applying only to the gestation then current. Did you use contraceptives? What method did you employ? [illegible] planned? When was contraception [illegible] fact that all the histories were taken by a single, interested person adds much to the accuracy and uniformity of the data. This was reimpressed on me when I recently attempted to analyze the contraceptive data from 1,000 histories at the obstetric clinic of the Johns Hopkins Hospital and the Sinai Hospital of Baltimore. They contained exactly the same questions, phrased in the same way, but many of the answers were left blank or at most only partially filled out. No doubt a time-deficient assistant resident simply asked, "Did you use contraceptives?" The patients almost uniformly answered in the negative, for in the blank after "contraceptive used" appears the word "none" in over 90 per cent. Yet the fact that in a sizeable proportion of these clinic patients several years had elapsed since the last pregnancy makes me exceedingly dubious of the accuracy of the information. Probably the patient did not know what the word contraception meant or, if she did, confused the word with a single technic, most likely the condom.

TABLE 1.—*Distribution of Pregnancies by Age and Religion of Wife, Occupation of Husband, Pregnancy Order, and Number of Children Living*

TABLE 2.—*Distribution of Pregnancies by Pregnancy Order and Planning Status*

| Pregnancy Order | Total | Contraception Not Used | | Contraception Discontinued | | Failure of Contraception | |
|---|---|---|---|---|---|---|---|
| | | No. | % | No. | % | No. | % |
| First | 919 | 219 | 23.8 | 581 | 63.2 | 119 | 12.9 |
| Later | 1,081 | 128 | 11.8 | 698 | 64.6 | 255 | 23.6 |
| Total | 2,000 | 347 | 17.4 | 1,279 | 64.9 | 374 | 18.7 |

In this survey of the records of 2,000 private patients, we hoped to determine four things. First, what percentage of our deliveries are the result of planned pregnancies? Second, what methods of contraception have our patients used? Third, what is the relative effectiveness of the various methods as employed by them? Fourth, how long did it take our patients to achieve pregnancy after abandoning contraception?

As a preliminary to further development of these points it is necessary to make clear how the material was assembled and analyzed. With the help of Mr. Omer Huesman, the statistical technician of the Department of Obstetrics at Johns Hopkins Hospital, a thirty-three column code sheet was drawn up. Two of us (A. F. G. and S. R.) coded the pertinent data from 2,000 consecutive obstetric histories; the code sheets in turn were transferred to punch cards by trained clerks. Appropriate tables were then constructed with the aid of a sorting machine. Statistical analysis of the data was made in collaboration with Dr. Christopher Tietze.

Before determining the answers to the four questions it is necessary that we present some basic facts about the patients who form the material of this study. All were married at the time of conception and all lived in Baltimore or its environs, the most distant point being Washington, D. C. The initial office visit was usually at the eighth or ninth week of pregnancy, when the historical data forming the basis of this study were taken. At this time the memory of contraceptive practice and the time necessary for conception was still fresh, and much more vivid than it would have been seven months later, just after delivery. Over 99 per cent of the patients were white, there being 17 Negro women and 2 Chinese in the group. The husbands of the Negro patients were largely of the professional class: teachers, doctors, ministers or engineers.

TABLE 3.—*Distribution of Pregnancies by Number of Children Living and Planning Status*

| Number of Children Living | Total | Contraception Not Used | | Contraception Discontinued | | Failure of Contraception | |
|---|---|---|---|---|---|---|---|
| | | No. | % | No. | % | No. | % |
| None | 1,111 | 275 | 24.8 | 696 | 62.6 | 140 | 12.6 |
| One or more | 889 | 72 | 8.1 | 583 | 65.6 | 234 | 26.3 |
| Total | 2,000 | 347 | 17.4 | 1,279 | 64.0 | 374 | 18.7 |

## ANALYSIS OF DATA

Table 1 gives the general composition of the group. The majority of subjects, 62 per cent, were in the third decade of life, and more than 85 per cent were between the ages of 20 and 35. Sixty per cent of the women were Jewish. The Christians were not divided into Protestants and Catholics, though it is believed the Catholics were much outnumbered. Almost 30 per cent of the husbands were professional men: doctors, medical students, scientists, dentists, clergymen, teachers, engineers and lawyers. Twenty-three per cent were either business owners or executives. About 38 per cent were white collar workers, and the remaining 10 per cent manual workers. Most of the latter were *immigrés* to the local shipyards during the war. We found it impossible to classify the group in the armed forces by social-economic status, since all but a few were temporary soldiers rather than professional. The group was equally divided between officers and enlisted men.

The highly selected social-economic character of the clientele is reflected by the data on pregnancy order and the number of living children, the group being heavily weighted by women in their first pregnancy. Many classified as second pregnancies had only produced an abortus or a child which did not survive, as the 9.6 per cent difference between those in the first pregnancy and those with no living children indicates.

With this groundwork established—this delineation of the manner of man and woman making up the sample—we are now ready to consider the first question. What percentage of our deliveries are the result of planned pregnancies? The answer is set forth in tables 2 and 3. Of the 2,000 pregnant women who came to the obstetrician, 374, or 18.7 per cent, came regretfully, since they had not abandoned contraception and became pregnant despite its continued use. A much larger group, 1,279, or 64 per cent, came gleefully, having abandoned successful birth control with the goal to achieve pregnancy. Only 347, or 17.4 per cent, became pregnant without having used any contraceptive at all, some since the day of marriage, others since the termination of the previous pregnancy. Further analysis shows that 219 did not use contraception from the day they married. This group was mainly made up of the relatively elderly who could not afford to waste precious reproductive time, the very young who did not know the facts of life and the devout Catholics. The smaller group, 128, did not use contraception between the previous pregnancy and the current one under analysis. In almost every instance the previous pregnancy had terminated in an early spontaneous abortion. Patients in this study almost uniformly employed contraception for a variable period after a viable pregnancy.

TABLE 4.—*Pregnancies Following Contraception by Method Used*

| Method | Pregnancies | % |
|---|---|---|
| Condom | 669 | 43.3 |
| Diaphragm and jelly | 644 | 41.7 |
| Douche | 75 | 4.9 |
| Withdrawal | 72 | 4.7 |
| Rhythm | 46 | 3.0 |
| Suppositories | 21 | 1.4 |
| Cream or jelly alone | 17 | 1.1 |
| Several methods | 99 | .... |
| Not recorded | 10 | .... |
| Total | 2,000 | 100.0 |

If the group of patients who did not use contraceptives is added to those who abandoned contraceptives to achieve pregnancy, it appears that 81.4 per cent of the patients had wanted pregnancies. This figure is probably too high for the segment of population which our sample represents. First, it is unfair to assume that all who did not use contraception at any time after marriage or after a previous pregnancy actually wanted a baby immediately. Some probably mentally planned not to have a baby and either ignorantly, or devoutly, trusted to the fickle cooperation of nature. Second, unquestionably some members of the population went to the illegal abortionist and not to the obstetrician when contraception failed them. It is impossible to calculate or even estimate the size of either group.

We should like to point out from table 3 that contraceptive failure terminating in obstetric care was much commoner among the 889 women who had living children than among the 1,111 who had no living children. In fact, the incidence of failure was about twice as great. This must be due chiefly to the fact that the couples with living children have had a greater average duration of contraceptive exposure; does it also mean that they are less careful or that previous childbirth renders them anatomically less efficient for contraceptive success? More profound analysis, at a later date, of our complicated master work tables might furnish a solution to these questions.

TABLE 5.—*Pregnancies Following Contraception by Method and Planning Status*

| Contraceptive Method Used | Total Cases | Contraception Discontinued | Failure of Contraception | % Failures |
|---|---|---|---|---|
| Condom | 669 | 570 | 99 | 14.8 ± 1.4 |
| Diaphragm and jelly | 644 | 533 | 111 | 17.2 ± 1.5 |
| All others | 340 | 176 | 164 | 48.2 ± 2.7 |
| Total | 1,653 | 1,279 | 374 | 22.6 ± 1.0 |

The 18.7 per cent ratio of contraceptive failures is much lower than that reported by Whelpton and Kiser [2] in their Indianapolis study. They found that a little over half of all pregnancies not terminated by illegal abortion were the result of ineffective contraceptive methods. This difference between 19 per cent and 53 per cent is chiefly due to the fact that our material is drawn from the upper and middle classes to a much greater extent than the group reported from Indianapolis, where the sample consisted of urban, native-white Protestant couples with the minimum of an eighth grade education.

The second question we proposed, what methods of contraception have our patients used? is answered in table 4. The analysis includes the 64 per cent who abandoned contraception in order to conceive and the 18.7 per cent in whom conception was accidental and unwanted. Together the condom and diaphragm represented 85 per cent of the total contraceptives used. The 99 subjects whose histories are not included in our computations because they used "several methods" were largely couples who used the condom on one occasion and the diaphragm on another. A smaller number used the safe period in conjunction with the condom or diaphragm.

Certainly no one would claim that our observations are representative of a large segment of the population.

TABLE 6.—*Planned Pregnancies by Duration of Exposure*

| Mo. of Exposure | No. of Pregnancies | % of Pregnancies |
|---|---|---|
| 1 | 395 | 31.9 |
| 2 and 3 | 382 | 30.8 |
| 4 to 6 | 220 | 17.7 |
| 7 to 12 | 140 | 11.3 |
| 13 to 24 | 53 | 4.3 |
| 25 to 36 | 23 | 1.9 |
| Longer | 27 | 2.2 |
| Not recorded | 39 | .... |
| Total | 1,279 | 100.0 |

Koos [3] in 1947 showed that there are striking class differences in the employment of contraceptive measures. This report confirmed the earlier observations of Riley and White,[4] who showed that not only class but geographic area, size of community, age and religion affect the choice of contraceptive technic. From the previous literature plus our own study, one might postulate that in this country at least, the sophistication of any social group is in direct proportion to their use of the condom and diaphragm and in inverse proportion to their use of withdrawal and the postcoital douche.

[4] Riley, J. W., and White, M.: The Use of Various Methods of Contraception, Am. Sociol. Rev. **5**: 890-903 (Dec.) 1940.

The answer to question three, what is the relative effectiveness of the various methods as employed by them? is set forth in table 5. First, it is apparent that of the 1,653 pregnancies which were preceded by contraception, 374, or 22.6 per cent, occurred despite the continued use of contraceptives. We cannot say from this that our clientele's contraceptive methods are 77.4 per cent effective. We are still faced with the unknown number of contraceptive failures which are terminated illegally. Furthermore, in such a population sample there are couples who remain steadfastly undesirous of children. These never find their way to the statistical tables of the obstetrician or the clandestine corridors of the abortionist, because they practice contraception consistently and successfully throughout marriage.

We can say from table 5 that the condom and diaphragm as used by this population sample offered about equal protection and that they were equally superior to the other contraceptive methods. This is in line with earlier reports by many authors.

Table 6 answers the fourth and final question, how long did it take our patients to achieve pregnancy after abandoning contraception? Approximately one-third became pregnant immediately at the first ovulation after contraception was discontinued; another 30 per cent, at the second or third ovulation. In total, 62.7 per cent of the pregnancies occurred within the first three months and 90.8 per cent within the first year after the elimination of birth control. To be sure, there must have been an unknown number in this population who were chagrined because, in spite of the discontinuance of contraceptive practices, pregnancy did not result. They, too, have no path leading to these tables.

## SUMMARY

1. Almost two thirds of the 2,000 pregnancies occurred after contraception had been discontinued for the avowed purpose of initiating pregnancy. An additional sixth of the sample had not used contraception at all. Only 19 per cent of the pregnancies were the result of actual contraceptive failure.

2. The condom and the diaphragm were equally popular. These two methods were used by more than 85 per cent of those who practiced contraception in the group surveyed.

3. The relative effectiveness of the condom and the diaphragm, as used by this group, was approximately the same. These devices were far more effective than the other methods employed.

4. Three fifths of the planned pregnancies occurred within three months, and more than nine tenths within one year from the time contraception was discontinued. To us this seems decidedly significant. It might furnish the obstetrician and gynecologist grounds to pause and consider. It has been customary for the physician to show little interest or concern in the reproductive disappointments of a couple until sterility has continued for at least two, and usually three years. On the basis of these data we propose that one year is long enough.

1109 North Calvert Street (2).

# THE SUBCUTANEOUS ADMINISTRATION OF MERCAPTOMERIN (THIOMERIN®)

### Effective Mercurial Diuretic for the Treatment of Congestive Heart Failure

ROBERT C. BATTERMAN, M.D.
DAVID UNTERMAN, M.D.
and
ARTHUR C. DeGRAFF, M.D.
New York

The popularity and widespread use of the mercurial diuretics reflect the pharmacologic advances in obtaining preparations with a high degree of effectiveness and a minimal degree of toxicity. The presence of theophylline chemically linked to one valence of the mercury atom of the compound is the major reason for this favorable therapeutic range. It has been demonstrated that theophylline decreases the affinity of the mercurial for tissue, since it decreases the area and severity of irritation at the site of injection,[1] increases the rate and completeness of absorption from the site of intramuscular injection,[2] increases the elimination of mercury by the kidney[3] and increases the diuresis.[4] In terms of clinical usage this means that local irritation at the site of injection is lessened, that the predictability of obtaining a satisfactory response is high when the diuretic is administered intravenously and that on intramuscular injection, because of complete absorption, this predictability of response is also approached. In spite of the advantages attained by the theophyllinated mercurial diuretics, their use is still fraught with several dangers. The most serious is the occurrence of systemic reactions. In a review of the toxic manifestations of mercurial diuretics in man, DeGraff and Nadler[5] intimated that such reactions are becoming more frequent, particularly when the intravenous route of administration is used, and that a fatal outcome, although rare, is a possibility that must always be kept in mind. Further work[6] has demonstrated in the experimental animal that death is caused by the action of these drugs on the heart, with ventricular fibrillation as the terminal event. This observation is in accord with the clinical interpretation of the toxic manifestation.

Since to our knowledge death has not been reported with the intramuscular use of the mercurial diuretics this route of administration has become the one of choice by many. This technic, however, is not entirely satisfactory because: (1) the predictability of obtaining a satisfactory diuresis by intramuscular injection is

less than that by the intravenous route; (2) the diuresis when obtained is slower in onset and less in degree than that obtained after intravenous injection, and (3) the available mercurial diuretics are still exceedingly irritating, necessitating deep intramuscular injection to avoid sloughs and excessive pain. Nevertheless, many patients complain of pain at the site of injection and nodule formation is not uncommon.

A mercurial diuretic which overcomes many of the objections inherent in the currently available preparations is known as mercaptomerin sodium (thiomerin sodium®),[7] the disodium salt of N(gamma-carboxymethyl-mercaptomercuri-beta-methoxy) propyl camphoramic acid. Lehman,[8] in a comparison of the acute cardiac toxicity of various mercurial diuretics, noted that this compound when judged in terms of immediate electrocardiographic changes in cats was less than one—one hundred and sixtieth as toxic as the maximum tolerated dose of mercurophylline injection (mercuhydrin®), which was the least toxic of the commercially available preparations. The new compound differs from the other mercurial diuretics in that the theophylline complex is replaced by a mercaptide group (fig. 1). The chemical structure of mercurophylline injection differs from that of mercaptomerin sodium only in the replacement of theophylline by the monothiol, sodium thioglycollate.

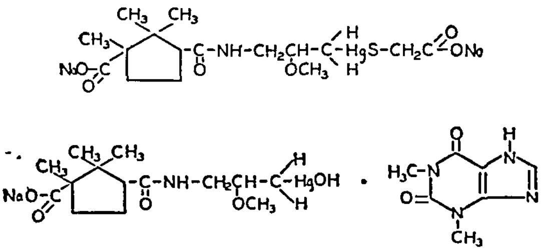

Fig. 1.—Structural formulas of mercaptomerin sodium (thiomerin sodium®) and, below, of mercurophylline injection (mercuzanthin®).

Not only is the cardiac toxicity decreased by this substitution, but the amount of local irritation at the site of injection is minimized to such a degree that the preparation is relatively painless for the patient on subcutaneous injection. Initial studies revealed that such an injection, although not entirely free of irritation, can be given with little if any discomfort to the patient and that the occurrence of nodular formation at the site of injection is unusual.

Since this appeared to be of definite advantage, the diuretic effectiveness when administered subcutaneously was determined in 6 patients with anasarca due to congestive heart failure not responding to rest in bed, maximum tolerated daily doses of digitalis and restricted salt and fluid intake. The urinary output was followed by means of continuous bladder catheterization. After a control period of thirty to sixty minutes each subject was given 2 cc. mercaptomerin sodium subcutaneously. Figure 2 illustrates the urinary flow in cubic centimeters per minute over a six hour period. It will be observed that the diuresis begins approximately one hundred and five minutes after the injection and reaches a sustained diuresis of over 5 cc. per minute in approximately one hundred and sixty-five minutes. This diuresis persists for two and one-half hours and gradually subsides, although at the termination of the study, or six hour period, the urinary output is still increased.

CLINICAL OBSERVATIONS

The effectiveness and safety of mercaptomerin for the treatment of congestive heart failure was studied according to several plans. First, an effort was made to compare the predictability of an effective diuretic response following an intravenous or subcutaneous injection of the drug with an intravenous injection of mercurophylline. For this purpose hospitalized patients with varying degrees of congestive heart failure were given the diuretics when the preliminary control period indicated that sufficient time had elapsed to evaluate concomitant therapeutic measures such as bed rest, digitalization and dietary restrictions. This method for studying diuretics has proved most satisfactory in our hands and has been reported previously.[9] By follow-

ing the weight curve, it is possible to exclude those patients who have a spontaneous diuresis on bedrest alone or those patients who respond to digitalization. The diuretic is administered when the weight curve remains stable or indicates further accumulation of edema fluid. A diuretic response is considered effective if the patient loses at least 3 pounds (1.3 Kg.) of edema fluid over a period of forty-eight hours. In a comparison of the diuretics in the same patient, the edema fluid was allowed to accumulate to approximately the same degree before the diuretic was given.

Forty-five patients were the subjects in this phase of the investigation. The effectiveness of mercaptomerin as compared to mercurophylline for the removal of edema fluid of patients with congestive heart failure is presented in the accompanying table. From the data on predictability to achieve a satisfactory diuresis—that is, a weight loss of 3 pounds (1.3 Kg.) or more—it would appear that mercaptomerin when administered subcutaneously is a decidedly satisfactory diuretic. The predictability of response in each of the three groups of patients, whether they received mercurophylline intravenously, mercaptomerin intravenously or the latter drug subcutaneously, is for all practical purposes identical. Further evidence which indicates the similarity of degree of diuresis for the subcutaneous administration of the latter as compared with the intravenous administration of either of the two diuretics is depicted in figure 3. Inadequate diuresis or failure to respond with mercaptomerin was the result usually of (1) lack of ammonium chloride, (2) digitalis therapy or (3) terminal heart disease and corresponded to our previous experience with other mercurial diuretics.

*Predictability of Obtaining a Satisfactory Diuresis*

| | | | | Diuresis | | | | | |
|---|---|---|---|---|---|---|---|---|---|
| | | | | Satisfactory | | Inadequate | | Failure | |
| Diuretic | Route | No. of Patients | Trials | No. | % | No. | % | No. | % |
| Mercurophylline injection | Intravenous | 30 | 72 | 60 | 83.3 | 7 | 9.7 | 5 | 6.9 |
| Mercaptomerin sodium | Intravenous | 32 | 58 | 47 | 81.0 | 8 | 13.8 | 3 | 5.2 |
| Mercaptomerin sodium | Subcutaneous | 27 | 60 | 52 | 86.6 | 6 | 10.0 | 2 | 3.3 |

In all patients urinalyses after administration of the diuretic revealed no abnormality. One patient had nausea and vomiting ten minutes after intravenous injection of mercaptomerin.

### USE OF MERCAPTOMERIN SODIUM FOR AMBULATORY PATIENTS

Thirty-five ambulatory patients attending the clinic for severe congestive heart failure were given mercaptomerin sodium whenever a mercurial diuretic was clinically indicated. All patients were on a maximum tolerated daily dosage of digitalis as well as ammonium chloride 3 Gm. a day. The diuretic in a dosage of 1 to 2 cc. was administered at weekly or biweekly intervals. The number of injections per patient varied between one and thirty-two, with the majority of the patients receiving more than four. In all, there were two hundred and twenty-six injections, of which two hundred and five were given subcutaneously, nineteen intravenously and two intramuscularly. Of particular interest was the subcutaneous route, which was effective in removal of the edema, prevention of the accumulation of edema and maintenance of the patients' state of compensation. In this regard it was as satisfactory as the previously used diuretics which were given intravenously or intramuscularly. In only 1 patient was there any systemic reaction. This consisted of mild chills, fever and diarrhea, which lasted for no more than two hours. It was similar to the reactions obtained previously with mercurophylline.

### TOLERANCE OF MERCAPTOMERIN SODIUM FOR HOSPITALIZED PATIENTS

Thiomerin® therapy was given a group of 73 hospitalized patients with the severest degree of chronic congestive heart failure that may be encountered in heart disease. All patients were at absolute rest in bed on a maximum tolerated daily dose of a digitalis preparation, ammonium chloride and restricted salt intake. Either mercurophylline injection or meralluride sodium solution (mercuhydrin®) by intravenous or intramuscular routes were used prior to administration of mercaptomerin sodium, so that the diuretic response of these agents was well known. The number of injections of mercaptomerin varied from one to twenty-two, with the majority of patients receiving five or more. In all, there were three hundred and thirty-four injections, of which all but ten were given subcutaneously. The usual dose was 2 cc., but in 7 instances, in which the patient required a higher dose of a mercurial diuretic for an effective response, 3 and 4 cc. were given subcutaneously to 5 and 2 patients, respectively. In general the diuretic response to the drug administered subcutaneously was as satisfactory as that to the previously used mercurial diuretics either intramuscularly or intravenously. In several instances the subcutaneous use of mercaptomerin gave a better response than the intramuscular injection of other mercurial compounds. Systemic reaction occurred in 1 patient and consisted of mild chills and fever both after a subcutaneous and after an intramuscular injection of the agent. It was similar to reactions noted previously in the same patient when mercurophylline injection was used.

### *LOCAL TOLERANCE*

The local tolerance of mercaptomerin sodium when administered intramuscularly was compared to that of meralluride sodium solution. Each subject was given 1 cc. of the diuretic into the gluteal area. Nine of 15 subjects who received meralluride had burning pain which persisted from ten minutes to several hours. One of these patients exhibited induration twenty-four hours after the injection. Ten of 24 subjects who received mercaptomerin had similar complaints, but without induration or nodule formation. To test further the local tolerance of the diuretic, the drug was injected in doses of 0.25 to 2 cc. subcutaneously in a group of 30 subjects. In all cases the injections were tolerated well, although with the higher dose of 1 or 2 cc. slight burning was noted, which subsided in a few minutes. In no instance was there any evidence of induration or nodular formation twenty-four hours after the injection. In another group of 7 subjects the effect of the subcutaneous injection of 1 cc. of the agent was compared with that of 1 cc. isotonic sodium chloride solution. In 3 subjects the degree of local irritation as evidenced by burning at the site of injection was the same for the two compounds. In 2 instances the diuretic was slightly more irritating, and in 2 other instances the isotonic sodium chloride solution proved more irritating.

In clinical practice, mercaptomerin sodium was given subcutaneously in doses of from 1 to 4 cc. for a total of five hundred and eighty-nine injections to 143 hospital and ambulatory patients with edema. Subjective burning at the site of injection was not an infrequent complaint, occurring after approximately 10 per cent of the injections. Tender induration which usually subsided within forty-eight hours was noted after approximately 4 per cent of the injections and nodules occurred after approximately 2.5 per cent. The incidence of local reactions in this study is somewhat higher than would be expected with the use of the currently available form of this diuretic considering that at the onset of the study several experimental lots of the compound were more irritating on injection. Nevertheless, the local reactions which have been mentioned are not clinically significant in the majority of cases, since the degree of irritation appears to be only slightly greater than that which results from the injection of isotonic sodium chloride solution. None of the patients refused continuation of this method of therapy because of local irritation. In several instances this was considered by the patients to be less than that noted with the previously administered intramuscular injection of meralluride sodium solution or mercurophylline injection.

### COMMENT

The combination of a mercaptan, sodium thioglycollate, rather than theophylline with the mercurial portion of a diuretic has removed many of the shortcomings present in the currently available mercury diuretics. In addition to a definite decrease in acute cardiac toxicity as evidenced by pharmacologic studies, mercaptomerin sodium also possesses many clinical advantages. Its decreased local irritation allows for greater ease in administration and acceptance by the patient. Not only is the subcutaneous injection of this diuretic well tolerated by over 90 per cent of patients, but the predictability of a satisfactory diuretic response is similar to that obtained by the intravenous route. Previous experience with currently available diuretics has demonstrated that the use of the intramuscular route is not ideal. In our desire to avoid the acute toxicity and reactions occasionally noted when the diuretics are administered intravenously, we have utilized the intramuscular route only to encounter several objections. Not only is local tolerance of the diuretics by this route unsatisfactory but the predictability of a diuretic response and the degree of diuresis are less than that obtained with the intravenous route. Many patients preferred to have mercaptomerin administered subcutaneously because they obtained a greater diuresis than that noted with other mercurial compounds given intramuscularly.

The predictability of a satisfactory diuretic response and the degree of diuresis by the subcutaneous use of this agent are similar to those noted with the intravenous administration of all mercurial diuretics. When a patient is receiving the currently available diuretics by the intravenous route and the response is poor, no greater response will occur by the substitution of mercaptomerin. However, if the mercurial diuretics have been used intramuscularly, substitution of the subcutaneous administration of this compound may result in a greater diuretic response.

It is too soon to state whether the use of mercaptomerin sodium will result in a lower incidence of systemic reactions other than cardiac. However, in view of the chemical similarity of this diuretic and mercurophylline injection, it could be predicted that patients who experience systemic reactions to the latter will also do so to the former. Two patients in our study manifested mild systemic reactions to mercaptomerin similar to those observed previously after use of mercurophylline. Thus, caution is required in the use of mercaptomerin, regardless of the route of administration, in those patients who have had systemic reactions to mercurophylline. With this exception we have found mercaptomerin to be a satisfactory and safe mercurial diuretic.

### CONCLUSIONS

1. Mercaptomerin (thiomerin®) is an effective and safe diuretic which may be administered subcutaneously to advantage with minimal irritation at the site of injection.

2. Although the subcutaneous administration of this drug may result in a slower diuresis, the predictability of a satisfactory diuretic response and the degree of diuresis achieved are similar to those noted with the intravenous use of mercurophylline injection.

3. Mercaptomerin sodium administered subcutaneously is superior to other mercurial diuretics administered intramuscularly.

## BENZODIOXAN TEST

### Fall in Blood Pressure Following Its Use in a Case of Renal Hypertension

ISABEL TALIAFERRO, M.D.
RAYMOND A. ADAMS, M.D.
and
H. B. HAAG, M.D.
Richmond, Va.

Goldenberg, Snyder and Aranow[1] have recently reported 4 proved cases of pheochromocytoma in which the adrenolytic benzodioxan drugs were first used as diagnostic agents. Benzodioxan derivatives (933 F, 2-[1-piperidylmethyl]-1,4-benzodioxan and 1164 F, [2,4-dimethyl piperidyl] methylbenzodioxan) given intravenously produced a significant fall in blood pressure lasting from thirteen to sixteen minutes in 3 cases and a "short and slight drop" in blood pressure in the fourth. Several of the same patients have been reported on elsewhere.[2]

Of the other drugs used in the diagnosis of pheochromocytoma it has been shown that histamine given intravenously causes a sharp rise in blood pressure[3]; similar results have been obtained by use of tetraethyl ammonium bromide[4] and methacholine bromide (mecholyl® bromide).[5] Dibenamine® hydrochloride (N,N-dibenzyl-beta-chlorethylamine hydrochloride) in one case depressed the hypertension.[6]

The patient whose case is reported herein is believed to have renal hypertension. The case is of interest because the blood pressure fell from 200 mm. of mercury systolic and 165 mm. diastolic to 120 mm. of mercury systolic and 98 mm. diastolic following the first benzodioxan test, while in two subsequent tests the fall was progressively less. The results of a fourth benzodioxan test performed six days after the first and a histamine test were negative.

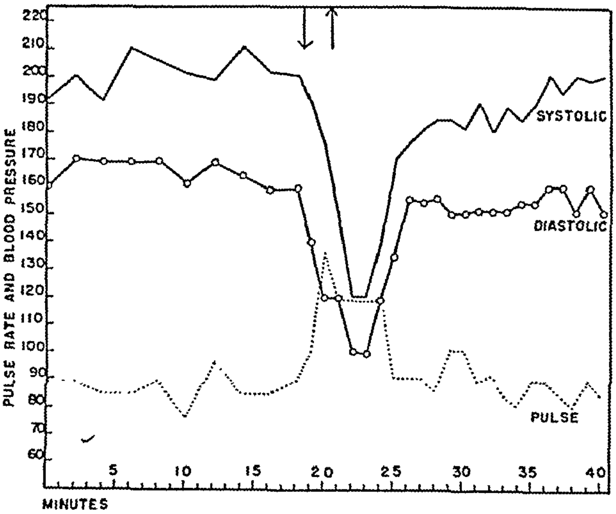

Chart 1.—Effects on blood pressure and pulse rate of first benzodioxan test: ↓ indicates beginning of injection and ↑ indicates end in this and succeeding charts.

REPORT OF CASE

*History.*—J. R., a Negro aged 18, entered St. Philip Hospital on Feb. 19, 1949 because of severe frontal headache of about one month's duration with associated vomiting and increasing drowsiness. The review of systems was negative; the remainder of the history was noncontributory. The patient stated that his blood pressure had never been determined.

*Physical Examination.*—Examination revealed a well developed and well nourished young man who was lethargic, acutely ill and complaining of severe headache. The blood pressure was 190 mm. of mercury systolic and 145 mm. diastolic, the pulse rate was 90 per minute, the respiratory rate 18 per minute and the temperature 99 F. The eyegrounds showed grade 4 retinopathy with arteriolar spasm, arteriovenous compression, haziness of the disk margins and many exudates. The heart was not enlarged, and there were no murmurs or thrills. The lungs were clear. Examination of the abdomen did not reveal masses or tenderness; the kidneys, liver and spleen were not palpable. The systolic blood pressure in the leg was greater than 260 mm. of mercury, and the diastolic pressure was 200 mm. Results of the neurologic examination were within normal limits.

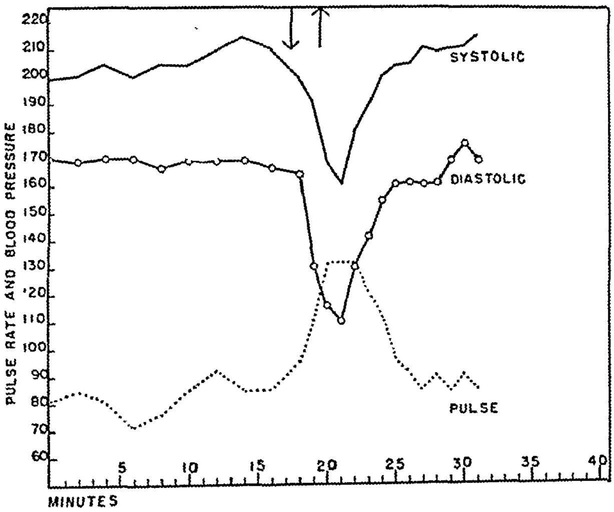

Chart 2.—Effects on blood pressure and pulse rate of second benzodioxan test.

*Laboratory Data.*—Examination of the blood revealed the following: hemoglobin 18 Gm., red blood cells 6,740,000, white blood cells 5,200 and a normal differential count. The packed cell volume was 54 per cent. The nonprotein nitrogen level of the blood was 76 mg. and the creatinine determination 6.3 mg., per hundred cubic centimeters. Reactions of the blood to flocculation and Wassermann tests were positive. Blood chlorides were 102, carbon dioxide-combining power 26, sodium 148 and potassium 5.9 milliequivalents per liter. Several urinalyses revealed 2 to 4 plus reactions for albumin, 7 to 15 red blood cells and up to 20 white blood cells per high power field, with occasional casts in the spun sediment. In a Mosenthal concentration test the greatest specific gravity was 1.015. A phenolsulfonphthalein test showed 32 per cent excretion in two hours. Urine cultures demonstrated hemolytic streptococci and Escherichia coli.

An electrocardiogram showed left axis deviation. On a roentgenogram of the chest the lungs were found to be clear, and the cardiac silhouette was normal. Cystoscopic studies revealed delayed excretion of indigo carmine, and retrograde urograms disclosed no abnormalities except bifid renal pelves.

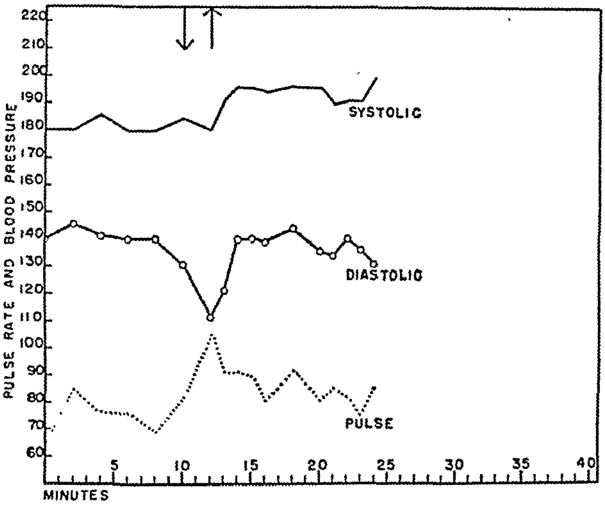

Chart 3.—Effects on blood pressure and pulse rate of third benzodioxan test.

*Treatment and Course.*—During the first week in the hospital the blood pressure ranged from 188 to 220 mm. of mercury systolic and 145 to 190 mm. diastolic. There was one reading charted as 140 mm. of mercury systolic and 70 mm. diastolic, but this was believed to be almost certainly an error.

On February 25 the patient was given 16.8 mg. (10 mg. per square meter) of benzodioxan[7] in a 1 per cent solution in sterile water intravenously during a period of two minutes. The blood pressure, which had averaged about 200 mm. systolic and 165 mm. diastolic fell to 120 mm. systolic and 98 mm. diastolic within three and one-half minutes, while the pulse rate increased from 95 to 135 beats per minute. The blood pressure and pulse returned nearly to preinjection levels in eight and six minutes, respectively (chart 1). The result was considered positive and evidence in favor of pheochromocytoma. It was then realized that the patient had received 30 mg. of phenobarbital four times a day during the preceding three days (no other medicament had been given). Earlier workers have found that normal animals anesthetized with amobarbital (amytal®) manifest a drop in blood pressure after administration of benzodioxan,[8] and Goldenberg and associates[1] have pointed out the clinical implications of these observations. The consideration therefore arose that the fall in blood pressure in this patient might have been associated with the administration of phenobarbital. The phenobarbital therapy was consequently discontinued, and on February 26, fifteen hours later, the second benzodioxan test was made, giving 18 mg. of the drug in 1 per cent solution in two minutes intravenously. A definite fall in blood pressure and tachycardia were again observed (chart 2). However, the fall in systolic blood pressure was less than in the first test.

---

[7] The benzodioxan (2-[1-piperidylmethyl]-1,4-benzodioxan) used in these studies was supplied by Dr. R. C. Pogge of Merck & Co., Rahway, N. J.

The third test, performed on February 28, with 18 mg. of the drug in 1 per cent solution given intravenously in two minutes, resulted only in a brief fall in the diastolic pressure and a slight tachycardia (chart 3).

To investigate further any possible relation between the barbiturate which the patient had received and the response to benzodioxan, phenobarbital, 30 mg. four times a day, was begun again on March 1. On March 3, with the control blood pressure 158 mm. of mercury systolic and 124 mm. diastolic, the fourth benzodioxan test was performed using 18 mg. in 1 per cent solution intravenously in two minutes (chart 4). No significant change in systolic or diastolic blood pressure or in pulse rate was observed. The depressor effect of benzodioxan therefore seemed to diminish with each test and to be unrelated to the previous administration of this dose of phenobarbital.

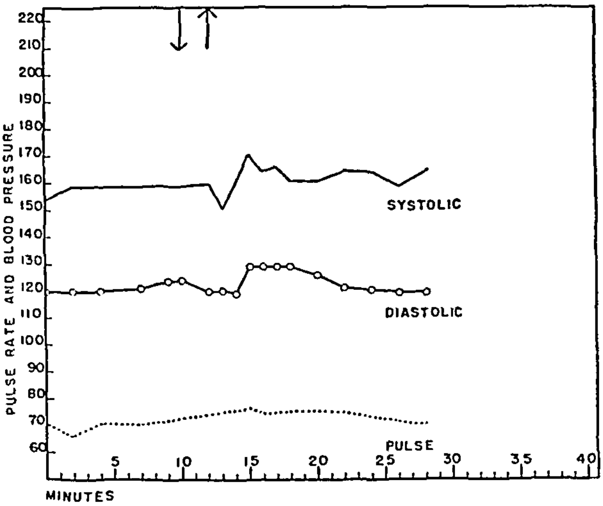

Chart 4.—Effects on blood pressure and pulse rate of fourth benzodioxan test.

In view of the current opinion that pheochromocytoma may cause sustained (as well as paroxysmal) hypertension, this diagnosis was still considered tenable. Therefore certain other diagnostic drugs, previously mentioned, were used. Five mg. per kilogram of dibenamine® (by intravenous drip in 400 cc. of 5 per cent dextrose) resulted in negligible changes in blood pressure. Tetraethyl ammonium chloride (400 mg. intravenously) produced a profound fall in blood pressure. This response is characteristic of essential or renal hypertension in contradistinction to the results reported by LaDue, Murison and Pack in their case of pheochromocytoma.[4] A histamine test[3] was performed, using 0.05 mg. histamine base intravenously. This resulted in a transient fall in blood pressure followed by a slight rise over resting values of about 10 mm. of mercury, constituting again a negative reaction for pheochromocytoma. Methacholine bromide was not used.

During his hospitalization the patient was treated with bed rest, antibiotics for the urinary tract and for syphilitic infections and the Kempner rice diet. He rapidly became asymptomatic. The lesions of the optic fundi regressed but did not disappear, and the resting blood pressure fell gradually to about 130 mm. of mercury systolic and about 90 mm. diastolic. After antibiotic therapy cultures of the urine exhibited no growth. The nonprotein nitrogen level of the blood fell to 41 mg. per hundred cubic centimeters, but renal function did not improve as measured by the Mosenthal concentration and phenolsulfonphthalein excretion tests. The patient was discharged on the thirty-eighth day, to be followed in the outpatient department. It was believed that the diagnosis of pheochromocytoma was excluded by the clinical course and the studies described. The final diagnosis was renal hypertension.

## COMMENT

The most striking observations in this case of hypertension were the initial depressor response to benzodioxan administration and the disappearance of this response on subsequent injections of the drug.

It might be argued that the previous administration of phenobarbital caused the depressor responses of the first benzodioxan tests, but in our opinion this did not obtain. Evidence for this view is the failure to duplicate these initial results on readministration of the barbiturate. Furthermore, in several other patients with chronic hypertension who were previously given large amounts of barbiturates no fall in blood pressure following administration of the benzodioxan derivative has been observed.

## CONCLUSION

Studies on this patient lead us to conclude that there is need for caution in interpreting a depressor response after benzodioxan as evidence of the presence of pheochromocytoma.

## ADDENDUM

The patient was seen at frequent intervals in the outpatient department, and it was noted that the hypertension and azotemia gradually returned. Subsequent to the submission of the foregoing report and seven weeks after the patient's discharge from the hospital he died at home. Permission for necropsy could not be obtained.

# TREATMENT OF A PATIENT WITH A PHEOCHROMOCYTOMA

## Use of an Adrenolytic Drug Before and During Operation

K. S. GRIMSON, M.D.
F. H. LONGINO, M.D.
C. E. KERNODLE, M.D.
and
H. B. O'REAR, M.D.
Durham, N. C.

Since Goldenberg, Snyder and Aranow[1] reported their experiences using 2-(1-piperidylmethyl)-1,4-benzodioxan (933 F) in the diagnosis of hypertension caused by circulating epinephrine liberated from functioning tumors of the adrenal medulla, many have confirmed their results. Possibility of failure and value of other tests have been reviewed by Roth and Kvale.[2] It is well known that pheochromocytomas, whether associated with paroxysmal or persistent hypertension, are removed with difficulty because anesthetic agents and operative manipulation often cause excessive elevations or fluctuations of blood pressure and subsequent reduction and shock. The present high surgical mortality rate (3 of 20 operations reported in the literature since 1943, as reviewed by Hatch, Richards and Spiegl[3]) is attributed to epinephrine intoxication. Injection of

epinephrine can cause increase or decrease of blood pressure. Also, tumors may contain epinephrine or non-epinephrine.[4] Behavior of a patient who has a pheochromocytoma with circulating epinephrine and who is then treated continuously with an adrenolytic drug is therefore problematic and has not to our knowledge been reported. Experiences during treatment of 1 patient will be described. Incidentally, among 61 patients with hypertension tested by use of 2-(1-piperidylmethyl)-1,4-benzodioxan this is our first patient who had definite reduction of blood pressure. Also, he is the only one with a proved pheochromocytoma.

### REPORT OF CASE

L. H., a Negro boy aged 10 and weighing 21.9 Kg., gave a history of recurrent abdominal pain on the right side, progressive fatigue and exertional dyspnea during ten months. Examination revealed a blood pressure of 184 mm. of mercury systolic and 150 mm. diastolic; there was retinal edema with early papilledema, hemorrhages and exudates; the pulse rate was 145 per minute. Electrocardiograms were interpreted as within normal limits except for tachycardia. Blood sugar levels on three occasions were 111, 114 and 120 mg. per hundred cubic centimeters. Tests of renal function were normal, and the nonprotein nitrogen determination was 29 mg. per hundred cubic centimeters. Blood potassium and sodium and also serum and urine chloride determinations yielded normal values. Intravenous urograms did not demonstrate abnormality.

During eighteen days of observation the blood pressure remained elevated, fluctuating between 208 systolic and 160 diastolic and 176 systolic and 130 diastolic. Episodes of sweating, headache, tachycardia and greater rise of blood pressure recurred frequently during examination or with excitement. Intravenous administration of 2-(1-piperidylmethyl)-1,4-benzodioxan (0.25 mg. per kilogram of body weight) was associated with reduction of blood pressure from 180 systolic and 150 diastolic to 128 systolic and 114 diastolic on one day and from 182 systolic and 140 diastolic to 146 systolic and 110 diastolic on another. Reduction lasted about fifteen minutes. Histamine phosphate injected intravenously (0.0005 mg. per kilogram) reduced blood pressure from 194 systolic and 150 diastolic to 166 systolic and 135 diastolic for three minutes, following which pressure rose to 212 systolic and 170 diastolic. Determination of blood adrenalin by W. W. Shingleton[5] revealed high values.

Nineteen days after admission to the hospital operative intervention was planned, and preoperative preparation using an adrenolytic drug was attempted. 2(N,para-tolyl-N [m-hydroxyphenol]-aminomethyl)-imidazoline hydrochloride (C 7337)[6] was selected from the many adrenolytic and sympatholytic drugs available as theoretically the most suitable for trial. Blood pressure, which fluctuated from 156 systolic and 134 diastolic to 218 systolic and 156 diastolic the morning of operation, was reduced to 80 systolic with the diastolic reading not obtainable immediately following intravenous injection of the adrenolytic drug, 0.33 mg. per kilogram. Within two minutes the blood pressure returned to 112 systolic and 84 diastolic. It remained at this level during the next forty minutes. The pulse rate increased to 170 per minute during the first two minutes following this injection and then remained around 90. The patient's condition seemed satisfactory and anesthesia was induced using ethylene supplemented by ether and d-tubocurarine chloride. Pressure rose gradually during the next twenty minutes while anesthesia was induced and the patient prepared. When it had reached 160 systolic and 138 diastolic the intravenous injection of the adrenolytic drug was repeated using a smaller amount, 0.08 mg. per kilogram. The blood pressure then decreased to 140 systolic and 116 diastolic. The operation lasted one and one-half hours. During the first fifty minutes, injections of the drug (0.08 mg. per kilogram) were repeated four times, whenever the blood pressure rose. Each injection was followed by a reduction toward normal values. During the trauma of exploration of the adrenal glands and manipulation and removal of a tumor 4.5 cm. in diameter and the right adrenal gland there was no associated increase of blood pressure. Fluctuations of the blood pressure during the first fifty minutes of operation ranged from 150 systolic and 130 diastolic to 200 systolic and 166 diastolic, but these fluctuations correlated with the injections of the adrenolytic agent rather than with trauma and possible expulsion of adrenalin into the blood stream. Injections were discontinued after the tumor was removed. The blood pressure decreased gradually to values around 100 systolic and 70 diastolic during the twenty minutes of operation following removal of the tumor. It remained at normal levels around 120 systolic and 80 diastolic continuously during the immediate postoperative course and the thirteen days that lapsed to the time the patient was discharged from the hospital. It was 106 systolic and 68 diastolic two and one-half months later. Retinitis cleared except for old exudates, and symptoms were relieved. Pathologic examination revealed that the tumor was a benign pheochromocytoma.

### COMMENT

This experience is reported because it confirmed the impression of the authors that adrenolytic drugs are useful, although probably not infallible, in the diagnosis of adrenalin-secreting tumors and that they may also be employed to treat hypertension associated with these tumors and to protect the patient against extreme fluctuations of blood pressure during anesthesia and operative removal of the tumor. Such fluctuations frequently lead to a vasomotor collapse, which contributes to the relatively great risk of these operative procedures. It is hoped that fluctuation of pressure and shock may be avoided in other patients who have this relatively rare type of tumor.

# TRANSMISSION OF STREPTOMYCIN-RESISTANT TUBERCLE BACILLI IN MAN

LIEUTENANT COMMANDER NORMA C. FURTOS
Medical Corps, United States Naval Reserve
Corona, Calif.
and
EDWIN A. DOANE, M.D.
Olive View, Calif.

A new and potentially serious problem of public health has been anticipated in view of the steadily increasing number of cases of pulmonary tuberculosis in which patients, after treatment with streptomycin, remain sputum positive with the tubercle bacilli highly resistant to streptomycin. We have learned by animal experimentation that such resistance is probably permanent and that a tuberculous infection resistant to subsequent streptomycin therapy can be transmitted from one animal to another. Finally, there is growing evidence to indicate not only that streptomycin is ineffective in combating such an infection but that its use may actually accelerate the tuberculous process. The following case report indicates that such transmission of streptomycin-resistant tuberculosis can occur in man.

### REPORT OF CASE

A woman aged 36, a lieutenant of the Navy Nurse Corps, was admitted to the sick list on June 28, 1947 at the United States Naval Hospital, Corona, Calif. Her known exposure to tuberculosis began Aug. 17, 1946, when she was assigned to the Streptomycin Study Unit at the United States Naval Hospital, Sampson, N. Y., during the course of which study a considerable number of the patients who were treated became highly resistant to streptomycin. Routine roentgenograms of the chest on Aug. 19, Sept. 10 and Dec. 4, 1946, revealed no evidence of pulmonary disease other than a small calcified nodule in the right third anterior interspace. This nurse had had no tuberculin tests until February 1947, at which time there was a negative reaction to purified protein derivative, first strength, while the response to a half-strength dilution of purified protein derivative, second strength, was questionable. A full second strength test was not given. A roentgenogram of the chest on March 3, 1947 revealed a minimal lesion in the right supraclavicular region which was not considered of clinical significance.

H.; Grimson, K. S.; Chittum, J. R., and Metcalf, B. H.: Effects of a New Quaternary Amine and a New Imidazoline Derivative on the Autonomic Nervous System, Surgery, to be published.

From the Streptomycin Study Unit, United States Naval Hospital, Corona, Calif. (Lieutenant Commander Furtos) and the Western Trudeau Streptomycin Laboratory, Olive View, Calif. (Dr. Doane).

On April 11, 1947 this nurse was transferred to the United States Naval Hospital, Corona, Calif., as part of the Streptomycin Study Unit which was being formed at that hospital. She then began to lose weight, noted a productive cough, fatigue and finally pain in the anterior region of the right lung. A roentgenogram of June 18, 1947 revealed an increase in the previously observed lesion, for which reason she was admitted to the sick list. The sputum was negative for tubercle bacilli, but a culture of gastric contents obtained June 30, 1948 was highly positive, and the bacteria grew readily in Dubos liquid mediums containing as much as 1,000 micrograms of streptomycin per cubic centimeter. On July 3 a tuberculin reaction to the first strength of purified protein derivative was reported as 2 plus. On a regimen of rest in bed a small rarefaction appeared in the lesion and gastric cultures remained positive. On Oct. 2, 1947 a right phrenicotripsy was performed, followed soon after by the induction of pneumoperitoneum. The clinical course was then satisfactory until February, 1948, when a low grade peritonitis developed, followed by a peritoneal effusion. Streptomycin therapy was considered at this point, but the drug was not given in view of the known high bacterial resistance. The intraperitoneal injection of air was abandoned, and the patient made an uneventful recovery. She was finally discharged from the hospital Nov. 1, 1948 with apparently arrested disease.

### COMMENT

Unfortunately, we are unable to definitely state whether this represented a primary infection or a so-called "reinfection," since the "questionable" reaction to tuberculin was obtained just two or three weeks prior to the time that the lesion was first detected roentgenologically. The presence of a well calcified nodule in the roentgenogram suggests a previous infection of some sort. The coccidioidin skin reaction was negative, and the patient did not at any time in the past reside in a region endemic to either coccidioidomycosis or histoplasmosis. We have examined more than 385 patients for the presence of possible resistance to streptomycin prior to beginning a course of streptomycin therapy, and in no other instance was initially high bacterial resistance detected except in patients who had previously been treated with streptomycin. With a definite history of continuous exposure to bacterial resistance, as was true in this case, it is exceedingly likely that the infection was derived from some such resistant source.

---

## STREPTOMYCIN-RESISTANT TUBERCLE BACILLI

### Isolation of Resistant Organisms from Pleural Fluid Prior to Institution of Streptomycin Therapy

ANDREW J. BRENNAN, M.D.
and
RUTH H. WICHELHAUSEN, M.D.
Washington, D. C.

The following case report confirms the prediction that tuberculous persons whose organisms have become resistant to streptomycin may transmit such resistant tubercle bacilli to those with whom they come in contact.

### REPORT OF CASE

J. Q. C., a Negro hospital attendant aged 32, was admitted to the Veterans Administration Hospital, Washington, D. C., on May 13, 1947 for chills, fever, generalized weakness, muscular pains, nausea and vomiting. Physical examination revealed a few scattered fine rales in the lower axillary region on the right side and a moderately loud friction rub. During the first week of hospitalization the patient had several chills and continued to have an elevation of temperature as high as 104.4 F. On the seventh day of hospitalization physical and roentgen examination revealed the presence of a pleural effusion. Thoracentesis yielded 460 cc. of clear fluid which was proved, by culture and guinea pig inoculation, to contain tubercle bacilli. Streptomycin therapy, 1.8 Gm. a day, was instituted on May 26 and continued for thirty-six days. Under this regimen the patient improved remarkably, and the temperature gradually declined. In the two months following the cessation of streptomycin therapy he felt well and gained 17 pounds (7.7 Kg.). However, diffuse cloudiness of the lower part of the right lung persisted, and his temperature continued to show slight elevations.

During the following year his temperature was normal and numerous studies of sputum and gastric washings for acid-fast bacilli were negative. A roentgenogram of the chest taken in March 1948 disclosed considerable clearing at the base of the right lung with obliteration of the right costal phrenic sinus by thickened pleura, but pulmonary parenchymal infiltration could never be demonstrated. Since discharge the patient has been going to school and remains well.

The acid-fast bacilli isolated in culture from the specimen of pleural fluid obtained on May 22, before the patient had received any antibiotic treatment, were tested by Dr. Monroe Romansky at George Washington University School of Medicine and found to be resistant to 100 micrograms of streptomycin per cubic centimeter.

The probable source of J. Q. C.'s infection was T. B. M., a white man aged 57, who had been admitted to the Veterans Administration Hospital, Washington, D. C., in November 1946 with miliary pulmonary tuberculosis. A detailed case report of this patient may be found in the *Journal of Medical Sciences* (**216**:290 [Sept.] 1948). He was treated with streptomycin, 3 Gm. a day for seven days and then 1.8 Gm. a day for one hundred and sixteen days. Acid-fast organisms obtained from him before initiation of streptomycin therapy were sensitive to 0.3 microgram of streptomycin, but after four months of therapy a culture was found to be resistant to 500 micrograms of streptomycin. In spite of this, he recovered under this treatment and was clinically well with negative sputum one and a half years after discontinuance of streptomycin therapy. He left the hospital two months prior to the onset of symptoms in patient J. Q. C., who had cared for him as attendant during his illness.

### CONCLUSION

Infection with streptomycin-resistant tubercle bacilli may be expected to become more frequent as the number of streptomycin-treated patients increases. In this instance it is possible to trace the infection to exposure to a patient whose organisms became streptomycin resistant during the course of his treatment. His improvement may have been due to the streptomycin therapy but was probably merely coincidental or due to the presence of a mixture of sensitive and resistant organisms. Other patients primarily infected by streptomycin-resistant tubercle bacilli may show much less favorable courses. Particular effort should be made to prevent further instances of such transmission of streptomycin-resistant tubercle bacilli.

SATURDAY, AUGUST 20, 1949

## RECOMMENDED PRACTICES FOR CONTROL OF POLIOMYELITIS

The imminent threat of widespread infantile paralysis beyond that of previous years has led to the release of statements by specially developed conferences which may well serve as a guide to physicians and the public. The New York City Department of Health on July 25, 1949, emphasized that the incubation period is seven to fourteen days but may be as short as three days or as long as forty-five days. The disease may be spread by (1) contact through discharges from the oropharynx, (2) fecal discharges and (3) flies. Although flies may be contaminated with the virus, reliable evidence is lacking of the spread of poliomyelitis by insects, water, food or sewage. During an epidemic infection is highly prevalent, but only a limited number of cases are clinically identifiable. For every known case between 10 and 100 persons have inapparent infection. Examination of the spinal fluid is an important although not specific diagnostic procedure. The period of greatest communicability is the latter part of the incubation period and the first week of acute illness. At least three groups of strains of poliomyelitis virus are now known, and infection with any one of these may or may not render the person infected immune to attack from the other two. Susceptibility to infection is general. Thus far the known vaccines, drugs, serums or antibiotics are without specific value against the disease.

The expectancy with regard to permanent crippling at the time of onset indicates that about 50 per cent will ultimately emerge free, about 25 per cent will have mild physical limitations, about 15 per cent will have severe crippling and about 5 to 10 per cent will die. Pregnant women are probably not more susceptible to poliomyelitis than other persons. Children born to women who have poliomyelitis during pregnancy or labor are normal. Fatigue in the early stage of poliomyelitis may influence adversely the extent of paralysis. Children should be prevented from becoming overfatigued during the poliomyelitis season.

The National Conference on Recommended Practices for the Control of Poliomyelitis, sponsored by the National Foundation for Infantile Paralysis, Inc., met in Ann Arbor, Mich., in June 1949 and formulated the following statements with respect to the control of the disease: Poliomyelitis is a highly prevalent infection, and only a small fraction of the cases is clinically identifiable. In its recognizable form it is an acute illness, usually febrile, with early varying symptoms, but usually with headache and almost always a characteristic stiffness of the neck and spine. In about half such cases a lower neurone paralysis develops in the first few days of illness. Diagnosis depends on detection of a flaccid paralysis characteristically irregular in its involvement of muscle or muscle groups. The cerebral spinal fluid shows usually a moderate increase in cells of all types. The period of greatest communicability is covered by the latter part of the incubation and the first week of the acute illness. Isolation should be practiced for one week from the date of onset or the duration of fever if longer than one week. Nose and throat discharges and feces are infectious and should be disposed of as quickly and safely as possible. Quarantine has not been proved valuable in limiting the spread of the disease.

The following points are stressed among the recommended epidemic measures:

1. General notice to physicians of the prevalence or increase of incidence of the disease, description of usual characteristics of onset and necessity of diagnosis and medical care, particularly for bed rest, and information to the public at large on similar matters.
2. Isolation in bed of all children with fever pending diagnosis.
3. Education in such technic of bedside nursing as will prevent distribution of infectious discharges to others from patients isolated at home.
4. Postponement of elective nose or throat operations or dental extractions.
5. Avoidance of excessive physical strain.
6. Avoidance of unnecessary travel and visiting, especially of children, during high prevalence of the infection.

No international measures were recommended.

All obvious and suspected cases should be promptly reported and classified as paralytic or nonparalytic. Diagnostic criteria should generally include three or more of the following: (1) history compatible with poliomyelitis, (2) fever, (3) stiff neck and/or stiff back, (4) 10 to 500 cells per cubic centimeter of spinal fluid taken during the acute or early convalescent period, (5) spinal fluid protein elevated above normal limits and (6) demonstrable muscle weakness or paralysis. In cases in which there is only (1) a history compatible with poliomyelitis and (2) fever, the condition should be classified as presumptive or abortive poliomyelitis.

Patients with acute poliomyelitis are admissible to a general hospital if appropriate isolation precautions are employed. Isolation procedures used for the care of patients with acute poliomyelitis are similar to technics used in the hospital care of other communicable diseases. Patients may be cared for at home if home facilities and medically supervised care are adequate.

Public and private schools should not be closed during an outbreak of poliomyelitis nor their opening delayed except for specific reasons. Schools to which children are transported in buses from widely separated areas or boarding schools, excluding colleges and universities, should delay opening sessions if an outbreak of poliomyelitis exists in the area where the school is located. Summer camps should open as usual unless there is an outbreak of poliomyelitis in the area in which the camp is located. Places of recreation and amusement need not be closed; however, the attendance of children at such places should be discouraged.

These recommendations were motivated by the desire to avoid as far as possible the effect of disturbing or altering unnecessarily the normal pattern of life in the community. Whatever is done to upset the usual routine of children in a household or of adults in their habits is likely to bring more trouble than good as far as control of infantile paralysis is concerned.

## THE DEMAND FOR MORE BEDS FOR THE TUBERCULOUS

Tuberculosis is an infectious disease, and segregation in a sanatorium is recognized, notwithstanding the development of antibiotic treatment, as a potent protective measure against infectious open cases of tuberculosis. A recent editorial[1] in the official publication devoted to tuberculosis reviews requirements for beds in proportion to deaths from tuberculosis. Although originally advocated as chiefly valuable for patients, the sanatorium, even at an early date, was considered valuable in diminishing the spread of the disease. When the death rate was high and sanatoriums were few, institutionalization for every patient throughout the period of active disease was considered impractical. That patients should receive sanatorium care even during the last years of their lives was believed visionary. Gradually such goals have been recognized. In 1916, a ratio of one bed per annual death was followed shortly by one and a half beds per death, a proportion advocated for nearly a generation. By 1929 this appeared too low, and in 1940 a goal of two beds per death was set as a minimum. States having as many as three beds per death were believed to be more than adequately supplied. As the tuberculosis death rate declined, three to six beds were utilized, but this is still far below the ideal of care in a sanatorium for every patient with active tuberculosis throughout the period of infectivity. Now our hospitals and sanatoriums for tuberculosis are overcrowded with cases of advanced disease; probably ten beds per death are required for institutional segregation for every patient in the United States with active tuberculosis.

"Tuberculin tests and fluoroscopic and roentgenographic examination of entire populations and intensive study of contacts of known cases of tuberculosis will reveal nearly all instances of active 'open' tuberculosis with cavity, the form responsible for most of the spread of the disease." With recognition of this as the goal, the responsibility for a definite number of preventable deaths from tuberculosis is placed on any delay in achievement of the ratio of ten beds per death. Patients with closed, arrested and inactive disease may be cared for in dispensaries, in offices or in their homes. The "open" case has been a continuously controversial subject since the discovery of the tubercle bacillus, and ". . . any patient who is expectorating tubercle bacilli is a potential hazard to his community and under ideal conditions should certainly be segregated so that danger of his spreading the disease may be averted."

The goal of ten beds per death is laudable. Some may justifiably ask about the rules for segregation and spread of tuberculosis. Can regulations be formulated drastically and efficiently with knowledge of the nature of this disease? Execution was necessary with cattle, and unfortunately tuberculosis is not a lethal but a "cryptic" carrier disease. The economics are not one sided or simple. Who shall support this program? Are we becoming visionary or dealing in reality? The supply of beds, though important, may be subsidiary to the standard of living and rooms per capita. With adequate rooms and qualified medical and nursing supervision, why cannot the intelligent limited active patient be cared for at home, returning to the sanatorium or hospital for a few months when necessary, rather than be subjected to compulsory hospitalization for years on the assumption that all cases are contagious? This question will have to be answered definitely as costs and controls increase.

## DR. PETER M. MURRAY, FIRST NEGRO MEMBER IN THE HOUSE OF DELEGATES

At the recent convention of the National Medical Association, leading Negro professional organization of the United States, Dr. George F. Lull, Secretary and General Manager of the American Medical Association, announced that a Negro physician, Dr. Peter M. Murray, has been elected by the New York State Medical Society to the House of Delegates of the American Medical Association. For twelve years Dr. Murray has been a member of the House of Delegates of the Medical Society of the State of New York. When Dr. Murray is seated in the House of Delegates at the San Francisco Convention of the American Medical Association in 1950, he will be the first Negro to serve as a member of this representative body.

Opponents of policies of the American Medical Association have charged frequently that Negro physicians have no opportunity in the Association. Any physician who is a member of his county medical society is also a member of the American Medical Association. The county medical societies have control over their own membership. Dr. Murray was elected by his colleagues in the New York State Medical Society House of Delegates. While Southern state medical societies have not customarily elected Negro physicians to membership, practically all Northern states have admitted reputable, duly licensed Negro physicians.

An invitation has been extended to licensed Negro physicians in the District of Columbia and to those who are members of the National Medical Association to attend sessions of the midwinter meeting of the American Medical Association. When Dr. Murray was asked by a reporter whether he would press for consideration of racial issues, he replied that he was elected as a representative from his medical society and would represent that membership.

## Current Comment

### CHRONIC IRRITATION AND CANCER

The concept of chronic irritation as one of the chief causative factors in human cancer retains wide acceptance. Experiences in occupational and experimental carcinogenesis, however, indicate increasingly that the agents that elicit cancerous reactions in man and animals are specific chemically and physically. Even apparently minor variations in the structure of chemical compounds may change a potent carcinogen into a noncarcinogenic chemical. Likewise, chronic irritative processes are not essential in carcinogenesis by specific chemical agents. Experimental as well as clinical observations indicate that chemical irritants may differ fundamentally in their action on the process of specific chemocarcinogenesis. While some of such nonspecific irritants apparently precipitate and accelerate development of cancer induced by specific carcinogens, others exert an inhibitory effect. Such differences may even be due partially to variations in the degree of the irritative action. While mild to moderate irritation, resulting in hyperemia and edema of the injured and carcinogenetically prepared tissues, not infrequently stimulates development of cancer, severe irritation sufficient to cause destruction of tissue may actually interfere with or impede this process. The concept of cancers resulting from chronic irritation is evidently based on the frequent coexistence of chronic inflammatory processes with precancerous and cancerous manifestations. Chronic cervicitis, chronic mastitis, chronic dermatitis following exposure to tar or roentgen rays and cirrhosis of the liver are considered conditions leading to cancer, and this supports the concept of carcinogenesis by nonspecific chronic irritation. However, there are experimental observations and particularly much clinical evidence to show definitely that chronic irritation as such is noncarcinogenic. Wherever cancerous processes are observed in chronically inflamed tissues a specific carcinogenic factor should be sought. In support of this concept as to the role of chronic irritation in carcinogenesis, cancers of the nasal sinuses are relatively rare although chronic sinusitis is one of the most common diseases. Chronic urethritis and chronic salpingitis also are rather frequently occurring diseases, while cancers of the male or female urethra and of the oviduct exhibit a conspicuously low rate of incidence. Recent studies of Carstam[1] have confirmed that hemorrhoids are not more frequent in cases with low cancer than in cases with tumors situated further up in the colon and are found with about equal frequency in patients with rectal or colonic cancers and in patients without intestinal cancer. Ashton[2] called attention to the fact that cancer of the cervix is rarely seen in the completely prolapsed uterus, although the cervix is subjected under such conditions to continuous physical and chemical irritation. Moreover, cancer is rarely seen in chronic crural ulcers. Finally, the development of cancer of the lung is seen with the inhalation of certain types of dust, fumes, vapors or gases (chromate, nickel carbonyl, tar, arsenic, radioactive agents and, perhaps, asbestos) but is not associated with the inhalation of others (silica, coal, cement). These observations suggest that greater efforts should be made in ascertaining specific causes of cancer which may be hidden behind common chronic irritative processes. Preventive control depends on the existence of such information. The conquest of infectious diseases was started only after the concept of a general miasma had been destroyed by the demonstration of specific causes.

### DR. LULL AWARDED LEGION OF HONOR MEDAL

His activities on behalf of the French people immediately after World War II have won for General George F. Lull, former Deputy Surgeon General of the United States Army and now Secretary and General Manager of the American Medical Association, the coveted Legion of Honor medal from the French government. Formal presentation of the medal was made by Jean Joseph Viala, French Consul General, in Chicago Wednesday, July 27.

His appointment as Deputy Surgeon General of the United States Army in 1943 climaxed a career in Army medicine started in 1912, during which he served in all grades from lieutenant to major general. He was awarded the Distinguished Service Medal for his activities in World War II.

### BLOOD BANK CONFERENCE

There are approximately 1,513 blood banks in the United States according to the progress report of the American Medical Association's Committee on Blood Banks which met in Chicago, July 21.

Dr. Leonard W. Larson of Bismark, N. D., chairman of the Committee, and two members, Drs. H. P. Ramsey and W. D. Stovall of Washington, D. C., and Madison, Wis., acting as a subcommittee, met with representatives of the American Hospital Association, American Association of Blood Banks, American College of Surgeons, American Protestant Hospital Association, American National Red Cross, American Society of Clinical Pathologists, Catholic Hospital Association, College of American Pathologists and National Research Council. Most of the meeting was devoted to a detailed line by line examination of the proposed questionnaire which is to be sent to all of these blood banks during August by the Committee on Blood Banks. The questionnaire states that the survey is being made by the Committee on Blood Banks of the American Medical Association in cooperation with these nine other associations.

The Committee has been charged by the House of Delegates with the responsibility for making a survey of the blood bank situation in the United States with a view to appraising the quantity of the blood procured, processed and distributed as well as to formulate tentative plans for coordination of blood banks in any national emergency.

The following table presents the number of blood banks in each state reported at the meeting:

| | | | |
|---|---|---|---|
| Alabama | 24 | Nebraska | 10 |
| Arizona | 13 | Nevada | 1 |
| Arkansas | 10 | New Hampshire | 7 |
| California | 85 | New Jersey | 46 |
| Colorado | 15 | New Mexico | 4 |
| Connecticut | 26 | New York | 151 |
| Delaware | 4 | North Carolina | 40 |
| District of Columbia | 12 | North Dakota | 7 |
| Florida | 28 | Ohio | 86 |
| Georgia | 28 | Oklahoma | 15 |
| Idaho | 8 | Oregon | 13 |
| Illinois | 97 | Pennsylvania | 112 |
| Indiana | 31 | Rhode Island | 9 |
| Iowa | 32 | South Carolina | 12 |
| Kansas | 37 | South Dakota | 10 |
| Kentucky | 22 | Tennessee | 31 |
| Louisiana | 20 | Texas | 50 |
| Maine | 7 | Utah | 7 |
| Maryland | 32 | Vermont | 6 |
| Massachusetts | 78 | Virginia | 32 |
| Michigan | 69 | Washington | 21 |
| Minnesota | 25 | West Virginia | 24 |
| Mississippi | 17 | Wisconsin | 33 |
| Missouri | 54 | Wyoming | 1 |
| Montana | 11 | TOTAL | 1,513 |

The nine cooperating agencies were represented by: Dr. Albert M. Wolf, American Association of Blood Banks; Drs. Charles F. Branch and H. P. Saunders, American College of Surgeons; Mr. Maurice Norby, American Hospital Association; Reverend Joseph A. George, American Protestant Hospital Association; Drs. G. F. McGinnis, Ross T. McIntire and Herbert Brown, American National Red Cross; Dr. Larson, American Society of Clinical Pathologists; Reverend James V. Moscow, Catholic Hospital Association; Dr. M. G. Westmoreland, College of American Pathologists, and Dr. E. L. DeGowin, National Research Council.

### POPULARITY PRIZE WINNER (ART)

During the recent annual session of the American Medical Association in Atlantic City, the winner of the popularity prize offered by the American Physicians Art Association was no. 289B, "Midnight Report" (oil) by Dr. Irving L. Kohn, New York. The runners up were 406A, "New England Coast" (oil) by Dr. H. B. Mussina Williamsport, Pa.; 371A, "Central Park South — The Witching Hour" (oil) by Dr. M. M. Melicow, New York, and 256A, "The Bride" (oil) by Dr. James C. Janney, Wellesley, Mass.

## *Washington Letter*

*(From a Special Correspondent)*

Aug. 15, 1949.

### Capitol Tempo Stepped Up on Health Legislation

As Congress entered on what was expected to be the last month of its present lengthy session, bipartisan efforts were redoubled to achieve enactment of several important bills of national significance affecting medicine and allied professions. The first ten days of August, for example, witnessed the following developments:

Passage by the Senate of a bill (S. 614) amending the Hill-Burton hospital construction act by doubling the federal contribution to $150,000,000 annually and otherwise liberalizing the law.

Favorable action by Senate Labor and Public Welfare Committee on S. 1453, federal aid to medical schools with provision for a scholarship system. Enactment of this measure by both branches of Congress and approval by the President is considered probable.

Approval by the House subcommittee on health legislation of its own bill (H. R. 5903) amending the Hill-Burton act, and which is substantially the same as S. 614. Also, subcommittee approval of a revised bill (H. R. 5865) on federal aid to local public health units. This bill likewise is similar to S. 522, and its chances of passage by the Senate are considered good.

Other legislation, less broad in scope, which advanced on the road toward enactment during the same period included S. 2160, passed by the Senate, which gives commissioned personnel of U. S. Public Health Service leave privileges comparable with those enjoyed by Army and Navy officers; H. R. 5324, increasing salaries of medical and certain other professional personnel in Veterans Administration, on which public hearings were held by the House Veterans Committee, and H. R. 5940, a companion bill to the Senate bill on aid to medical education, which is under committee consideration.

### Legion Endorses Higher Salaries for VA Doctors

At public hearings August 9 on H. R. 5324, the Allen bill on increasing salaries of physicians, dentists and nurses in Veterans Administration, in all professional grades, supporting testimony was presented by spokesmen for the American Legion. Witnesses were T. O. Kraabel, director of the Legion's National Rehabilitation Commission, and Dr. Hyman David Shapiro, senior medical consultant.

At several junctures in the hearing, Chairman John E. Rankin (Dem., Miss.) of the House Committee on Veterans Affairs made short statements expressing criticism of certain medical practices and trends in professional education. This country needs more doctors of the "horse and buggy" type, he asserted. Younger physicians, particularly psychiatrists, came in for generalized criticism at the hands of the committee chairman. Apropos of doctor shortages in certain areas of the country, Rankin said:

"The making of a closed shop of the medical profession has done infinite harm and I'm going to try to do something about it."

At one point during testimony by Dr. Shapiro, who is a psychiatrist, Representative Rankin interrupted to say: "What the Veterans Administration needs is doctors, not psychiatrists."

Later the same day, the Mississippian introduced bills authorizing construction of a 200 bed veterans hospital at Tupelo and another of the same size at Mound Bayou.

### Josephine Roche Reports on Miners' Medical Program

Milestones in the medical and hospital program of the United Mine Workers Welfare and Retirement Fund were described to the Senate Banking and Currency Committee on August 1 by Miss Josephine Roche, director of the Fund.

Expenditures for the health program totaled $4,761,071 during the last twelve months, Miss Roche testified, providing hospital and medical care for 26,480 miners and dependents. She credited the cooperation of national, state and local medical organizations, medical schools and the profession generally for a large measure of the success that has been achieved in getting the program off to a sound start.

"That this program has moved ahead so steadily and constructively is due to the careful consideration and circumspection given each minute detail and problem and to each step before it is taken," Miss Roche said. "Also greatly contributing to its growing success are the constantly available advice and consultations, the cooperation and interest coming to us from preeminent physicians and surgeons and from leading medical organizations and institutions of the nation."

### Humphrey's Minority Report Demands Department of Welfare

On August 10, which was the Wednesday preceding the Senate vote on establishment of a Department of Welfare, Senator Huber H. Humphrey (Dem., Minn.) issued a twenty-four page minority report designed to lessen opposition to the reorganization plan. He was a member of the Senate Expenditures Committee group of four who voted against the McClellan resolution expressing disapproval of the plan for a new executive department.

Vehemently denouncing the educational campaign of the American Medical Association, Humphrey said it was responsible for the adverse vote in committee and charged that if the plan "is killed because of the opposition of one lobby on behalf of a small group that is not even affected by it except in imagination, then we shall have offered proof that a democratic government cannot order its own affairs effectively. This is the test."

The Humphrey statement was given nationwide circulation not only through the press and the Senator's office but also through Federal Security Agency, Committee for the Nation's Health and other organizations sympathetic to compulsory health insurance and establishment of a Department of Welfare.

### June Figures on Veterans Care Program Disclosed

Physicians participating in the Veterans Administration "home town" medical care program gave 61,991 medical examinations on a fee basis during the month of June, according to the latest VA report. A total of 37,804 patients received the examinations. Treatments during the same period numbered 222,974, administered to 67,454 patients. The cost for examinations and treatments averaged $7.92 and $4.13, respectively.

### $2,056,426 in Federal Research Grants Announced

Federal Security Agency has announced the award of $2,056,426 in grants for continued support of two hundred and seventeen medical and allied research projects under way in ninety-four institutions. They comprise chiefly medical schools, universities and hospitals in thirty-one states, the District of Columbia, Alaska, Canada, Denmark, Norway and Guatemala. Awards for new projects are still being withheld, pending possible action by Congress reducing appropriations of Public Health Service and other government agencies. The projects include studies of deafness and speech defects, peptic ulcers, the common cold, relation of the endocrine glands to aging, changes induced in the living cell by irradation, the longevity and behavior of pathogenic bacteria in frozen food, and the viability of enteric bacteria in sea water and factors controlling the fate of sewage after discharge in the sea.

### Poliomyelitis Epidemic is Subject of New York Conference

A New York conference August 9-10 between Children's Bureau doctors and staff members of the National Foundation for Infantile Paralysis was announced August 5 by Federal Security Administrator Oscar R. Ewing. How to make public and private funds go the farthest in fighting poliomyelitis was to be the subject of the conference.

---

## Coming Medical Meetings

Aero Medical Association, New York, Aug. 29-Sept. 2. Dr. Thomas H. Sutherland, 214 S. State St., Marion, Ohio, Secretary.
American Academy of Ophthalmology and Otolaryngology, Chicago, Oct. 9-14. Dr. W. L. Benedict, 100 First Avenue Bldg., Rochester, Minn., Secretary.
American Association of Obstetricians, Gynecologists and Abdominal Surgeons, Hot Springs, Va., The Homestead, Sept. 8-10. Dr. Leroy A. Calkins, University of Kansas Medical Center, Kansas City 3, Kan., Secretary.
American Congress of Physical Medicine, Cincinnati, Netherlands Plaza Hotel, Sept. 6-10. Dr. Richard Kovacs, 2 E. 88th St., New York 28, Secretary.
American Hospital Association, Cleveland, Sept. 26-29. Mr. George P. Bugbee, 18 East Division St., Chicago, Executive Secretary.
American Roentgen Ray Society, Cincinnati, Oct. 4-7. Dr. H. Dabney Kerr, University Hospitals, Iowa City, Iowa, Secretary.
American Society of Clinical Pathologists, Chicago, Drake Hotel, Oct. 11-15. Dr. C. G. Culbertson, 740 S. Alabama St., Indianapolis, Secretary.
Colorado State Medical Society, Denver, Shirley-Savoy Hotel, Sept. 20-23. Mr. Harvey T. Sethman, 835 Republic Bldg., Denver, Executive Secretary.
Delaware, Medical Society of, Wilmington, Oct. 13-16. Dr. W. Edwin Bird, 822 North American Bldg., Wilmington, Executive Secretary.
Gulf Coast Clinical Society, Pensacola, Fla., Oct. 6-7. Dr. Arthur J. Butt Jr., Pensacola, Fla., Secretary.
Indiana State Medical Association, French Lick, Sept. 25-27. Mr. Ray E. Smith, 1021 Hume-Mansur Bldg., Indianapolis 4, Executive Secretary.
International Congress of Biochemistry, Cambridge, England, Aug. 19-25. Lieut. Col. Francis J. Griffin, 56 Victoria St., London, W.C.1, Organizer.
International Neurological Congress, Paris, France, Sept. 5-10. Dr. Raymond Garcin, 19 rue de Borgogne, Paris, General Secretary.
Kansas City Southwest Clinical Society, Kansas City, Mo., Municipal Auditorium, Oct. 3-6. Dr. W. Merritt Ketcham, 630 Shukert Bldg., Kansas City, Mo., Secretary.
Kentucky State Medical Association, Owensboro, Oct. 6-9. Dr. Bruce Underwood, 620 S. Third St., Louisville 2, Secretary.
Michigan State Medical Society, Grand Rapids, Pantlind Hotel and Civic Auditorium, Sept. 21-23. Dr. L. Fernald Foster, 2020 Olds Tower, Lansing 8, Secretary.
Mississippi Valley Medical Society, St. Louis, Jefferson Hotel, Sept. 28-30. Dr. Harold Swanberg, 209-224 W. C. U. Bldg., Quincy, Ill., Secretary.
Nevada State Medical Association, Elko, Sept. 29-Oct. 1. Dr. Roland W. Stahr, 118 California Ave., Reno, Secretary.
Northern Minnesota Medical Association, Alexandria, Sept. 9-10. Dr. C. L. Oppegaard, Crookston, Secretary.
Oregon State Medical Society, Eugene, Oct. 12-15. Dr. Werner E. Zeller, Medical-Dental Bldg., Portland 5, Secretary.
Pennsylvania, Medical Society of the State of, Pittsburgh, Hotel William Penn, Sept. 26-29. Dr. W. F. Donaldson, 8104 Jenkins Arcade, Pittsburgh 22, Secretary.
Southern Minnesota Medical Association, Red Wing, Sept. 12, Dr. W. A. Merritt, Rochester, Secretary.
Southwestern Surgical Congress, Houston, Tex., Shamrock Hotel, Sept. 26-28. Dr. C. R. Rountree, 525 N.W. Eleventh St., Oklahoma City 3, Secretary.
Utah State Medical Association, Salt Lake City, Sept. 1-3. Dr. Ray T. Woolsey, 42 S. Fifth East St., Salt Lake City 2, Secretary.
Vermont State Medical Society, Burlington, Sept. 8-9. Dr. James P. Hammond, 542 Main St., Bennington, Secretary.
Virginia, Medical Society of, Fort Monroe, Old Point Comfort, Oct. 9-12. Miss Agnes V. Edwards, 1200 E. Clay St., Richmond ,Sechetary.
Washington State Medical Association, Seattle, Olympic Hotel, Sept. 11-14. Dr. James W. Haviland, 338 White-Henry-Stuart Bldg., Seattle, Secretary.
Wisconsin, State Medical Society of, Milwaukee, Hotel Shroeder and Milwaukee Auditorium, Oct. 3-5. Mr. Charles H. Crownhart, 704 E. Gorham St., Madison, Secretary.
World Medical Association, General Assembly, London, Eng., Oct. 10-15. Dr. Louis H. Bauer, 2 E. 103d St., New York City, Secretary General.
Wyoming State Medical Society, Casper, Sept. 12-14. Dr. George H. Phelps, 1606 Capitol Avenue, Cheyenne, Secretary.

# GOVERNMENT SERVICES

## SECRETARY OF DEFENSE

### ASSISTANT FOR CIVIL DEFENSE LIAISON

Establishment of the position of Assistant for Civil Defense Liaison in the Office of the Secretary of Defense was announced with the appointment of Lieut. Col. Barnet W. Beers to this position.

The creation of this new staff position results primarily from the necessity of assuring effective coordination of National Military Establishment activities which are closely related to civil defense with the activities of those civilian government agencies which have been made responsible for civil defense planning as such. The ultimate objective is to make certain that planning and preparations for civil defense are properly related to planning and preparations for military defense and that each complements the other.

Colonel Beers had been executive assistant in the National Military Establishment Office of Civil Defense Planning since it was first established, on March 27, 1948. This office has been abolished, and its files and remaining personnel have been transferred to the Assistant for Civil Defense Liaison.

## ARMY

### ARMY MEDICAL DEPARTMENT SENDS CONSULTANTS TO FAR EAST

A team of consultants, including three civilians and one Army physician, left Washington August 3 for a thirty-five day trip to the Far East Command under the Army's Civilian Consultants Program.

Representing the Army is Col. Warner F. Bowers, Chief, Surgical Consultants Division, Surgeon General's Office. The civilian consultants are Dr. Henry H. Kessler (orthopedics) of Newark, N. J.; Dr. Bruce Webster (internal medicine), New York, and Dr. Russell N. DeJong (neuropsychiatry), Ann Arbor, Mich.

The consultants will visit all Army hospitals in the Far East Command, including Japan, the Philippines, Okinawa and Guam. The Japanese Medical Society has arranged a reception in Tokyo at which Colonel Bowers will be the honor guest.

### ROTC CADETS BEGIN TRAINING COURSE

Approximately 100 ROTC cadets from ten medical colleges began a six week training course on August 1 at the Army Medical Center in Washington, D. C.

The cadets will receive one week of military instruction and five weeks of on-the-job training in the various phases of military medicine. They will be assigned to their preferred field of medicine and will observe the technic of Army doctors at Walter Reed General Hospital.

The students are all in their third year of medical college at the following schools: University of Pennsylvania, New York University, Yale University, Tufts School of Medicine, Harvard University, Boston University, Cornell University, Hendricks College in Conway, Ark., and Jefferson School of Medicine in Philadelphia. The cadets are all veterans of World War II and are attending their respective schools under the GI Bill of Rights.

### ADVANCED TRAINING

Fifteen Army Medical Department officers have recently been accepted for advanced training by civilian institutions. Included are three lieutenant colonels, six majors and six captains, representing the Medical, Veterinary, Medical Service and Army Nurse Corps. They are: Lieut. Col. Benjamin H. Sullivan Jr., MC, for training in clinical gastroenterology at the University of Pennsylvania, Philadelphia; Lieut. Col. Edward J. Doyle, MC, for training in surgical anatomy at Tufts College Medical School, Boston; Lieut. Col. James A. Wier, MC, for a course in diseases of the endocrines at Michael Reese Hospital Postgraduate School, Chicago; Major Neil G. MacEachern, VC, for training in Public Health at Johns Hopkins University, Baltimore; Major Jewell Derryberry, Major Martha C. Habib, Major Bernice Hill, Major Peggy G. Carbaugh, Major Frances Lay, Capt. Helen L. Tucker, Capt. Frances P. Thorp and Capt. Katherine Ball, all of Army Nurse Corps, for training in nursing education at the University of Minnesota School of Nursing, Minneapolis; Capt. Maxwell A. Cook, MSC, for training in psychiatric social work at the University of North Carolina, Chapel Hill; Capt. Marvin D. Blackburn Jr., MC, for training in pathology at St. Paul's Hospital, Dallas, Texas, and Capt. Carl B. Richey, MC, for training in internal medicine at Syracuse University, Syracuse, N. Y.

### ARMY ANNOUNCES COURSE IN PSYCHOTHERAPEUTIC MEDICINE

The Army Surgeon General has announced a two week course of instruction in the principles of psychotherapeutic medicine. In view of the acute shortage of psychiatrists in the armed forces, the course is designed to enable nonpsychiatrists to meet psychiatric problems in part.

Hospitals at which the course will be given and the beginning and terminating dates are as follows: Fitzsimons General Hospital, Denver, August 29-September 10; Letterman General Hospital, San Francisco, September 5-17, and Walter Reed General Hospital, Washington, D. C., August 29-Septmeber 10. The reporting date in each case is two days in advance of the beginning date. All class II installations have been allotted space.

The Surgeon General requests that, insofar as practicable, addressees make every effort to insure the assignment of key Medical Corps officers (chiefs and assistant chiefs of services) of the command, since each officer selected for training will be requested to disseminate the information gained in the course to the medical officers of his assigned station who are nonpsychiatrists. Medical officers who are trained psychiatrists will not be selected for this course.

Addressees will submit through channels the name, grade, serial number, military occupational specialty and duty assignment of each selected officer to: The Surgeon General, Department of the Army, Attention: Chief, Education and Training Division, for receipt not later than Aug. 19, 1949.

### SURGEON GENERAL'S OFFICE

Lieut. Col. C. A. McAllister, MSC, departed August 8 for duty in Japan. Colonel McAllister has been assigned to the Office of the Surgeon General since December 1948, as assistant chief, Operations Branch, Medical Plans and Operations Division.

Prior to this tour of duty he served in Japan from 1946 as operations officer, Medical Section, 8th Army, with headquarters in Yokohama.

Lieut. Col. Ernest T. Sheen, MSC, has been named as successor to Colonel McAllister. Colonel Sheen's last assignment was in Headquarters, 4th Army, Fort Sam Houston, Texas.

### ARMED FORCES INSTITUTE OF PATHOLOGY

Six ROTC medical students have been assigned to temporary duty at the Armed Forces Institute of Pathology from the summer camp at Walter Reed General Hospital. Three have been assigned to the Department of Pathology, where they are assisting individual pathologists in their work, and three have been assigned to the Army Museum to inventory and catalog anatomic specimens.

# Medical News

**(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)**

## ARIZONA

**Brooks Clinical Conference.**—The Harlow Brooks Memorial Navajo Clinical Conference will be held at Sage Memorial Hospital, Ganado, August 22-24. Out of state speakers include:

Henry M. Benning, Santa Barbara, Calif., Indications, Doses and Effects of Newer Antibiotics in Chronic Infections.
Harvey E. Billig Jr., Los Angeles, Factors in Essentials of Mobilization of the Human Body.
E. Forrest Boyd, Los Angeles, Report of a Case of Full Term Pregnancy Following Patent Ductus Ligation.
Felix Cunha, San Francisco, Case Histories in Gastroenterology.
Alfred E. Gallant, Los Angeles, And Now to Live.
L. Dale Huffman, Hollywood, Calif., Anticoagulants and Myocardial Infarction.
William R. Lovelace II, Albuquerque, N. Mex., Place of Radioactive Isotopes and Surgery in the Treatment of a Patient with Hyperthyroidism.
Malcolm T. MacEachern, Chicago, Patients, Doctors and Hospitals.
Joseph F. Montague, New York, Painless Proctology.
Thomas B. Noble Jr., Indianapolis, A Satisfactory Treatment of Acute Generalized Peritonitis with Multiple Intestinal Obstructions.
Daniel P. Quiring, PH.D., Cleveland, Human Types.
James P. Rigg, Grand Junction, Colo., Migraine.
Carl F. Rusche, Hollywood, Calif., Ureterosigmoid Anastomosis.
Buell H. Sprague, Hollywood, Calif., Thyroid Pathology Illustrated.
Ernest E. Tippin, Wichita, Kansas, Servicing Nature's Air Conditioner.

## CALIFORNIA

**Blood Bank Irradiates Plasma.**—Irwin Memorial Blood Bank, San Francisco, announced June 24 at its eighth anniversary that it is inaugurating a plan whereby plasma from the blood bank will be irradiated. It will be available for distribution by August 1. The new technic is to eliminate homologous serum jaundice. The sterilizing technic is not applicable to whole blood.

**Courses for Practicing Physicians.**—Stanford University School of Medicine, San Francisco, in cooperation with the San Francisco Department of Public Health and the San Francisco Hospital will present the following postgraduate medical courses for practicing physicians September 19-23: general surgery, internal medicine, dermatology, fractures, surgical anatomy and operative technic, laboratory diagnosis, endocrinology, surgical specialties, anesthesiology and clinical ophthalmology. The fee for registration, which closes September 1, is $75, payable to the Dean, Stanford University School of Medicine, 2398 Sacramento Street, San Francisco 15.

## COLORADO

**Seminar in Forensic Medicine.**—A series of seminars comprising an intensive review of medicolegal subjects will be conducted under the joint sponsorship of the University of Colorado School of Medicine, Denver, and the Office of the Medical Examiners of the City and County of Denver, September 23 and 24. The course offers lectures on medicolegal subjects which are of interest to all officials investigating the cause and manner of all obscure and violent deaths. Lecturers are, for the most part, persons actively engaged in the investigation of deaths and violence. The course is open to all coroners, coroner's physicians and prosecutors. There will be a registration fee of $10. Physicians who occasionally perform medicolegal autopsies and who may be interested in medicolegal work may register for these seminars. Additional information may be obtained from the Director of Graduate and Postgraduate Medical Education, University of Colorado School of Medicine, Denver.

## ILLINOIS

**To Prosecute Quack Doctors.**—The director of the State Department of Registration and Education, Noble J. Puffer, has notified his chief investigator to speed up prosecution against quack doctors operating in Chicago. As a result of a series of articles in the Chicago Tribune exposing medical quackery, thousands of inquiries have been received from readers who have been duped by the quacks. The department has also been conducting an investigation and will take prompt action in serving warrants and revoking licenses.

### Chicago

**Special Society Election.**—At the annual meeting of the Chicago Gynecological Society June 17 the following officers were elected: Dr. Eugene A. Edwards, president; Dr. John I. Brewer, president-elect; Dr. Edward M. Dorr, secretary, and Dr. Fred O. Priest, treasurer.

**War Memorial.**—A bronze plaque commemorating service and sacrifice will be erected as a war memorial at the 808 South Wood Street entrance of the University of Illinois' Chicago Professional Colleges. The plaque was recommended by a specially appointed War Memorial Committee. A War Memorial Fund of $1,300 will be used for the preparation of the plaque. The remainder of the fund will be used for the purchase of books related to military subjects.

**Magazine Racket.**—The Chicago Medical Society warns all doctors in the Chicago area to beware of two men who are attempting to launch a campaign for magazine subscriptions for which they do not have authority. The offer proposes purchase of a three year subscription to Newsweek and Clinical Medicine for $31.20, two of the following magazines then being supplied without charge: Coronet; Eye, Ear, Nose and Throat Monthly; Holiday; Judy's; Magazine Digest, and Nature Magazine. A deposit of $9 is requested, the balance to be mailed to Physicians Reception Service, 502 South Michigan, Chicago.

**Symposium on Plasma Proteins.** — A symposium on plasma proteins, sponsored by the Robert Gould Research Foundation, will be given under the auspices of the University of Illinois College of Medicine September 23 and 24 at the university. The symposium is designed to promote research and understanding of the subject. Sixteen prominent speakers will present aspects of the plasma proteins, such as formation, fractionation, immunologic and endocrine relationships, hypoproteinemia, relation to edema, isotope tracer studies and relation to the liver. One hundred and seventy-five guests who are interested in the subject have been invited to attend. The Robert Gould Research Foundation of Cincinnati is a nonprofit institution the activities of which are dedicated to public health and welfare. At the present time the foundation is devoting its funds primarily to the support of scientific research in the field of animal and human nutrition. The symposium on plasma proteins will be the second sponsored by the foundation. In October 1947 it supported a symposium on nutritional anemia, given under the auspices of the University of Cincinnati College of Medicine.

## INDIANA

**Dr. Badertscher Retires.**—Jacob A. Badertscher, Ph.D., professor of anatomy at Indiana University School of Medicine, Bloomington-Indianapolis, since 1914, will retire at the end of the summer school session, having reached the compulsory retirement age. He was given a farewell banquet in May that was attended by more than 300 of his former students. Dr. Badertscher has also been assistant dean at the medical school, where he will continue his research work.

**State Association Centennial Year.**—Dr. Augustus P. Hauss, president of the Indiana State Medical Association, has announced that the organization will celebrate its centennial anniversary at the annual meeting September 26-29. "The founding of the medical association in 1849 coincides with the birth of James Whitcomb Riley, Hoosier poet, who wrote numerous poems about physicians," said Dr. Hauss, "and the medical profession will honor his memory during our centennial meeting." Dr. Hauss has appointed Dr. Thurman B. Rice, Indiana University School of Medicine, Indianapolis, chairman of a committee to assemble a special historical exhibit.

## LOUISIANA

**University Appointments.**—The following appointments have been made to the Tulane University of Louisiana School of Medicine, New Orleans, for the 1949-1950 school year. Dr. Ernest Kun, instructor in pharmacology at the University of Chicago, and Dr. Nathaniel B. Kurnick, Karolinska Institute, Stockholm, Sweden, have been appointed assistant professors of medicine. Dr. Samuel Barkoff, senior psychiatrist at the Springfield State Hospital, Sykesville, Md., has been named associate professor of bacteriology.

**Grant to Further Psychiatric Program.**—A three year grant of $20,000 annually from the Edward G. Schlieder Educational Foundation of New Orleans has been made to Tulane University of Louisiana School of Medicine for development and expansion of clinical facilities in its psychiatric program. The grant will be used to pay salaries of additional personnel necessary for the program development, including social service workers, a psychiatrist and psychologist. Dr. Robert G. Heath, head of the newly created department of psychiatry and neurology, has estimated that facilities will permit treatment of approximately 300 underprivileged patients annually by the end of the third year of the program.

## MICHIGAN

**Charges Dismissed.**—Charges against Dr. Frederick W. Thomas, Detroit, were dismissed in the U. S. District Court *for the Eastern District of Michigan, Southern Division,* on June 6.

**Personal.**—Dr. Robert J. Buckman, Cincinnati, has been appointed medical consultant to the sales and promotion division of Parke, Davis & Company, Detroit. A graduate of the University of Louisville School of Medicine, 1930, Dr. Buckman spent 10 years in general practice in his home state of Kentucky and in Tennessee and 9 years in medical work in the pharmaceutic industry.

## MINNESOTA

**Personal.**—Dr. Benjamin W. Mandelstam, Gloversville, N. Y., on September 1 will become administrator of the new Mount Sinai Hospital in Minneapolis, which is to open next summer. He has been associated with Jewish Hospital of Brooklyn and Boston's Beth Israel Hospital and is presently executive director of the Nathan Littauer Hospital in Gloversville, N. Y.

**Postgraduate Medical Activities.**—During the last school year the activities of the department of postgraduate medical education at the University of Minnesota, Minneapolis, have returned to the prewar level, Dr. George N. Aagaard, director of the department, announced July 19 in his annual report. A total of 4,163 persons were enrolled in twenty-six continuation courses for physicians and twenty-five for nonphysician workers in medical fields. Special courses and new programs were mentioned in the report.

**Rural County Health Department.**—The Hennepin County Board of Commissioners on June 28 voted to establish a full time rural county health department. It will be under the control of a five man commission, composed of one doctor of medicine, one dentist and three laymen. A 1 mill levy on county residents will finance the community activity. The budget will provide for a full time health officer, and it is hoped that funds will be available for a public health engineer, a sanitarian and a health educator. Others will be employed as needed and to the extent that funds will permit.

## MISSISSIPPI

**Award Rural Medical Scholarships.**—Thirteen Mississippians were conditionally approved for state medical education loans by the State Medical Education Board at its meeting on July 30. The total number of students receiving state medical education loans, including those now in internship and those who have entered practice, is 202, representing seventy counties and one hundred and fifteen towns of the state. Seven of these students will be enrolled this fall at the University of Mississippi School of Medicine at Oxford, 3 at Tulane University, New Orleans; 1 at Emory University, Atlanta, Ga.; 1 at Columbia University, N. Y., and 1 at Harvard University, Boston.

## NEW YORK

**Early Care for Mental Illness.**—A pilot study in the promotion of psychiatric treatment as part of general hospital service will begin shortly at Roosevelt Hospital, New York, and Ellis Hospital, Schenectady, in cooperation with the State Department of Mental Hygiene. The experiments to be conducted will be directed toward the eventual decrease in the population of state mental hospitals.

**New York Post Graduate Lecture.**—The Cayuga County Medical Society will hear Dr. Joseph D. Godfrey, Buffalo, speak on "Treatment of Low Back Pain" September 15 at the Springside Inn, Auburn. The lecture has been arranged by the Medical Society of the State of New York in cooperation with the New York State Department of Health.

**Cancer Teaching Day.**—A cancer teaching day will be held September 14 beginning at 2 p.m. at the Homer Folks Tuberculosis Hospital, Oneonta, under the auspices of the New York Department of Health. The afternoon speakers will be Drs. Adrian A. Ehler, Albany; William H. Wehr, Buffalo, and Forrest O. Young, Rochester. At the evening meeting beginning at 7:30 Drs. Albert F. R. Andresen, Brooklyn, and Arthur J. Wallingford, Albany, will speak.

### New York City

**Open Russell Memorial.**—The James I. Russell Memorial Building of Roosevelt Hospital was opened June 29. The building is equipped to give medical treatment to 46 patients at one time and has an estimated capacity of 10,000 patients a year. It was named for Dr. Russell, who was a surgeon at the hospital for forty years.

**Create Division of Poliomyelitis.**—The City of New York Department of Health, "as part of definite plans to strengthen (its) facilities for handling the problem of poliomyelitis," has expanded its activities in this field by creating a Division of Poliomyelitis in the Bureau of Preventable Diseases. All epidemiologic work of the department on poliomyelitis will be centralized in the newly created division. Dr. Morris Siegel, a member of the city department of health since 1935, will head the division. In addition, the department's technical advisory committee on poliomyelitis has been reactivated. Creation of the new division and reactivation of the poliomyelitis committee do not indicate that the situation is alarming, an official said. These steps were taken as part of the department's plans for handling the problem should this become a bad poliomyelitis year for the city.

**Directory of Tuberculosis Clinics.**—The 1949 Directory of Tuberculosis Clinics in Greater New York was recently released by the New York Tuberculosis and Health Association. According to Dr. Donald B. Armstrong, president of the association, this directory will be published as frequently as necessary as a phase of the association's campaign to check the rising tuberculosis incidence rate in the city. The directory is an accurate reference to the 41 public and private clinics throughout the five boroughs, with addresses, phone numbers and clinic hours, as well as maps showing the boundaries for each district. Also included are the 21 district health centers for all boroughs. The directory was compiled under the direction of Dr. Foster Murray, chairman of the Tuberculosis Committee of the New York Tuberculosis and Health Association, and Mr. Donald E. Porter, secretary of the association's Tuberculosis Committee.

## OHIO

**University Appointments.**—Western Reserve University School of Medicine, Cleveland, has announced the following new appointments to the staff: Dr. Stuart H. Walker, Cleveland, who last year was a U. S. Army division surgeon, has been appointed professor of military science and tactics and fellow in pediatrics. J. Oliver Lampen, Ph.D., assistant professor of biochemistry at Washington University, St. Louis, was named associate professor of microbiology. A new assistant professor of pathology will be Dr. Russell S. Fisher, who has been resident fellow in legal medicine at Harvard Medical School, Boston.

**State Association Awards First Scholarship.**—The Ohio State Medical Association has granted its first annual Rural Medical Scholarship to C. Craig Wright of Winterset. Under the terms of the scholarship Mr. Wright will receive $500 each year during the four years he is in medical school. He completed his premedical training at Ohio State University. The scholarships were established to encourage rural young men and women to take up the study of medicine with the hope that they will become country doctors. One scholarship will be awarded annually to a freshman medical student. At the end of the first four year period and during subsequent years, each of four students will be receiving the annual $500 award.

## PENNSYLVANIA

**State Anesthesiologists Meeting.**—The annual meeting of the Pennsylvania State Society of Anesthesiologists will be held at the William Penn Hotel in Pittsburgh September 29 to October 1. For further information write Dr. William D. Steward, Secretary-Treasurer, Pittsburgh Society of Anesthesiologists, 5703 Jackson Street, Pittsburgh 6.

**Heart Disease and Drivers' Licenses.**—The Medical Society of the State of Pennsylvania, at the request of the Governor's Highway Safety Advisory Committee, has appointed a committee to study the problem of heart disease in automobile drivers. The committee will ascertain whether from the point of view of the medical practitioner it is possible and desirable to set up standards to protect the operator who has heart trouble, as well as passengers, pedestrians and property. The Governor's Highway Safety Advisory Committee has reported that each week at least one Pennsylvania operator of a motor vehicle is involved in an accident as a result of a heart attack and that a number of such drivers have died at the wheel. The committee comprises Dr. Constantine P. Faller, Harrisburg, chairman, and Drs. William G. Leaman Jr., Philadelphia; William L. Mullins, Pittsburgh; Wilfred H. Winey, Johnstown, and Luther I. Fisher, Bethlehem.

## UTAH

**Annual State Medical Meeting.**—The Utah State Medical Association will hold its annual meeting September 1-3 in the Union Building of the University of Utah in Salt Lake City. All physicians of the intermountain area are invited to attend. Guest speakers include:

Axel N. Arnesen, St. Louis, Treatment of Carcinoma of the Cervix Uteri.
Warren H. Cole, Chicago, Hyperthyroidism.
Irvin E. Hendryson, Denver, Early Diagnosis of Poliomyelitis.
Elmer Hess, Erie, Pa., Urologic Hints for the General Practitioner.
Elvin M. Jellenik, Sc.D., Fort Worth, Texas, Syndromes of Alcoholism.
Chester S. Keefer, Boston, New Antibiotic Drugs.
William P. Longmire Jr., Los Angeles, Total Gastrectomy.
K. Alvin Merendino, Seattle, Delay Factors in the Diagnosis of Carcinoma of the Esophagus.
Eric Oldberg, Chicago, Diagnosis and Treatment of Head Injuries.
Albert D. Ruedemann, Detroit, Acute Inflammatory Lesions Around the Eyes.
Shields Warren, Boston, Biologic Aspects of Atomic Energy.

The annual banquet will be held September 2.

## VIRGINIA

**Honor Dr. Coleman.**—Dr. Claude C. Coleman, professor of neurologic surgery at the Medical College of Virginia, Richmond, was honored at a scientific meeting commemorating the founding of the department of neurologic surgery at the college 30 years ago with Dr. Coleman as the department head. Technical papers were presented during the day, and at night about 70 persons attended a dinner at which Dr. Coleman was presented with a silver platter engraved with the names of his 15 hosts, who had trained under him.

## WISCONSIN

**University Appointment.**—Dr. Ray E. Green, Madison, has been appointed assistant professor of pharmacology at the University of Wisconsin Medical School, Madison. During the war he served at the Army chemical center in Maryland; on return to civilian life he was awarded a Rockerfeller fellowship as research assistant in pharmacology at the University of Wisconsin.

**Hospital Additions.**—Ground was broken for four new additions to State of Wisconsin General Hospital, Madison, early in July. When completed the additions will double the hospital bed capacity and provide more room for teaching needed to take care of the medical school's increased enrolment. Three new wings will be added to the present structure and a fourth unit, a one story lobby extension, will be used for offices and administration. One wing will be a cancer treatment unit; another will house psychiatric, neurosurgical and obstetric patients, and the third will centralize operative surgical facilities.

## GENERAL

**Board of Otolaryngology Examinations.**—The American Board of Otolaryngology will conduct the following examinations in 1950: January 8-11 in New Orleans at the Hotel St. Charles; May 17-20 in San Francisco at Hotel Mark Hopkins, and October 3-6 in Chicago at the Palmer House.

**Dr. Klotz to Receive Eli Lilly Award.**—The American Chemistry Society has given the $1,000 Eli Lilly and Company award in biological chemistry to Irving M. Klotz, Ph.D., associate professor of chemistry at Northwestern University, Chicago. He will receive the award September 19 at the national meeting of the society in Atlantic City. Dr. Klotz was cited for his services in several phases of protein chemistry.

**International Academy of Proctology.**—Officers elected at the first business meeting and scientific session of the International Academy of Proctology in Atlantic City June 10 are: Drs. Earl J. Halligan, president, Jersey City, N. J.; Caesar Portes, Chicago, president-elect; Alfred J. Cantor, Flushing, N. Y., secretary; William Lieberman, Brooklyn, N. Y., treasurer, and Earl J. Halligan, Jersey City, chairman of board of trustees (temporary). Membership is open to those specializing in proctology or allied fields. Information and application blanks may be obtained by writing to the academy, 43-55 Kissena Blvd., Flushing, N. Y.

**Congress on Pan American Medical Women.** — The second congress of the Pan American Medical Women's Alliance will be held in Los Angeles, November 1-6. Representatives are expected from all the Latin American republics as well as from the United States, Canada, Alaska and Hawaii. Members are invited to submit papers to the chairman, Dr. Alma Dea Morani, 3665 Midvale Avenue, Philadelphia 29, Pa., by September 1. The program committee is particularly interested in papers on the following subjects: modern use of antibiotics, virus diseases, rehabilitation programs, maternal and infant welfare, psychiatric problems, new drugs, cancer, and research for women doctors. The tentative program lists five scientific sessions.

**Inter-American Congress of Radiology.** — The Third Inter-American Congress of Radiology will take place in Santiago, Chile, at the Hotel Crillon November 11-17 under the patronage of the University of Chile. Papers delivered at the meeting will concern the radiologic exploration of the cardiovascular system with opaque material and diagnosis and simple radiologic explorations of the skull. Bilingual presentations of the proceedings of the meeting have been arranged. The registration fee of $20 should be sent to Dr. James T. Case, Regional Secretary for the United States, 55 East Washington Street, Chicago 2. The secretary will also provide full data on passports and other documents which congress members must carry with them.

**Passenger Safety Record for 1948.**—According to the National Safety Council, all major forms of transportation had a combined rate of 1.8 deaths per 100 million passenger-miles last year, the lowest in the 10 years that comparative records have been kept. Scheduled air transport planes showed the greatest improvement in 1948 as compared with 1947, although railroad passenger trains again had the lowest death rate. Scheduled air transport planes took 83 lives last year for a passenger-miles death rate of 1.3; the railroad passenger death total was 52 and the death rate 0.13. Buses had a rate of 0.18, although deaths totaled 120. Automobiles and taxis claimed the most passenger deaths with 15,200, but their mileage, 710 billion miles in 1948, brought the rate down to 2.1.

**Aero Medical Association Annual Meeting.**—The Aero Medical Association will hold its annual meeting August 29 to September 1 at the Hotel Statler, New York, under the presidency of Dr. Marion M. Kalez, Spokane, Wash. The program of the general meeting on Monday is as follows:

James H. Currens, Boston, Common Cardiac Conditions in the Young Male Adult.
Kinsey M. Simonton, Rochester, Minn., Observations of Hearing in Airline Pilots.
E. O. Errebo-Knudsen, Copenhagen, Denmark, Some Physiologic Reactions to the Passive Erect Posture.
Air Marshall Livingston, Preparation and Purpose of Parachute Medical Teams in the Royal Air Force.
John R. Poppen, Philadelphia, and R. R. Brown, Visual Problems in Designing Improved Indirect Lighting for Aircraft Cockpits.
Laurence E. Morehouse, Randolph Field, Texas, Electromyographic Study of Control Movements During Positive Radial Acceleration.

Section meetings will be held on the following days for the U. S. Air Forces, the Allied Specialties and the Civil Aeronautics Authority. Both scientific and commercial exhibits will be shown.

**Maxillofacial Surgeons' Meeting.**—The American Society of Maxillo-Facial Surgeons will hold its annual meeting in Montreal September 11-14 at the Royal Victoria Hospital and Montreal General Hospital. Included in the program are operative and dry clinics and lectures on carcinoma of the jaw, mouth and lip, repair of facial defects by bone grafts, treatment of defects of scalp and cranium, the child with cleft palate, sequelae of radiodermatitis, craniofacial injuries, management of fractures of the maxilla and associated bones, removal of salivary tumor from the mandible and its reconstruction, refrigerated bone grafts and pathologic conditions of the temporomandibular joint. Speakers will be Drs. John MacKay, Simeon J. Martin, John W. Gerrie, Frederick M. Woolhouse, Georges A. Cloutier, Hamilton A. Baxter, William U. Cone, John A. Drummond, William Douglas and Arthur R. Elvidge and Theo Waugh, all of Montreal; Drs. Carl S. Waldron, Samuel G. Balkin, Minneapolis; Fulton Risdon, Toronto; Carroll W. Stuart and Casper M. Epsteen, Chicago; John B. Erich, Rochester, Minn.; William Shearer, Omaha; John Kemper and Reed O. Dingman, Ann Arbor, Mich.; Robert L. Harding, Harrisburg, Pa.; V. H. Kazanjian, Boston, and Clifford Kiehn, Cleveland.

**Manual of Exchange Publications.**—UNESCO proposes to publish later in the year a Manual on the International Exchange of Publications. It is intended to publish as an annex to this manual a classified list of institutions, including libraries, universities, scientific institutions and learned societies throughout the world which are willing to exchange either their own publications or other publications which they have regularly at their disposal. UNESCO has been able to obtain a considerable amount of information concerning the availability of exchange material but feels that the information is still incomplete. All institutions which have so far not sent to UNESCO details of their exchange material are therefore urged immediately to communicate the following information to the UNESCO Clearing House for Publications, 19 Avenue Kleber, Paris 16ᵉ: (*a*) name and full address of institution and (*b*) exact titles of publications offered. (In the case of duplicates offered for exchange purposes, actual lists of duplicates are not required but only a statement that lists of duplicates are available. Institutions possessing a catalog of their own publications available for exchange are asked only to send a copy of the catalog or to give a full bibliographic description of the catalog.) Institutions which wish to exchange their publications only under certain conditions are asked to state these conditions. Only information which reaches UNESCO before October 1 can be used in the manual.

**Prevalence of Poliomyelitis.**—Reports of cases of poliomyelitis for the periods indicated have been received from the National Office of Vital Statistics, U. S. Public Health Service:

## CANADA

**Graduate Training in Ophthalmology.**—The University of Toronto Faculty of Medicine offers a three year postgraduate course in ophthalmology. The graduate instruction in ophthalmology in the teaching hospitals in Toronto has been coordinated under the direction of the university. The student spends the first year on a fellowship, the value of which is approximately $1,400, in one of the basic sciences of ophthalmology, and two years are spent on the intern service of one or more of the university teaching hospitals. Approximately four hours of didactic teaching are arranged for the students by members of the staff each week from October to May.

## LATIN AMERICA

**Congress on Phthisiology.**—The second Argentina Congress on Phthisiology will be held in Cordoba City in November. The official topics are (1) Technic and Results of BCG Vaccination; (2) Antibiotics in Treatment of Tuberculosis, and (3) Tuberculosis of Serous Membranes. Registration for the congress is through either of the offices of the secretaries of the Executive Committee: Santa Rosa 974, Cordoba, or Rio Bamba 476, Buenos Aires. The quota is 20 Argentine pesos ($4) for physicians and 100 Argentine pesos ($20) for representatives of private and official institutions and medical journals. The members who desire to present medical articles should notify the secretary of the Executive Committee one month before the congress, sending the title and conclusions of the article with the notification. Acceptance will be decided by the members of the board of directors of the congress. Reading time for each article is limited to 15 minutes.

## FOREIGN

**French Congress of Oto-Rhino-Laryngology.** — This congress will be held in the large amphitheater of the Faculty of Medicine of Paris October 17-21 under the chairmanship of Dr. André Bloch, Paris. Besides the scientific program, operations will be performed at the Hospital Services, conferences will be held and exhibits shown. For information address Dr. H. Flurin, Secretary-General à Cauterets (Hautes-Pyrénées), or Dr. H. Guillon, 6, Avenue Mac-Mahon, Paris.

**Professor Evans Retires.**—Prof. C. Lovatt Evans will retire from the chair of physiology, University College, London. Professor Evans first went to the University College in 1910 as Sharpey scholar in physiology under the late Prof. E. H. Starling. After Professor Starling's death Professor Evans completed "Starling's Principles of Physiology." During World War I Professor Evans served in the British army in connection with gas warfare and afterward joined the research staff at the National Institute for Medical Research, Hampstead, London, where he was associated with Sir Henry Dale. In 1922 he was appointed professor of physiology at St. Bartholomew's College and became Jodrell professor of physiology at University College, the position from which he is retiring.

# *Marriages*

Frederick Harrison Grabo, Schenectady, N. Y., to Miss Joan Catherine Coughlin of Pittsfield, Mass., June 18.

Rufus Solomon Gardner Jr., Hillsville, Va., to Miss Dorothy Ann Sutton of Newport News, June 21.

Wood S. Herren III, Birmingham, Ala., to Miss Ladye Ruth Holcomb of Nashville, Tenn., June 23.

Byron Jay Hoffman, Atlanta, to Miss Freda Gwendolyn Copeland of Brunswick, Ga., June 18.

Keith Woodham Gilmore to Miss Dorothy Louise Smith, both of Birmingham, Ala., June 17.

Elbert Neil Johnson Jr., Detroit, to Dr. Thelma Ruth Smith of Fort Mill, S. C., June 18.

Victor Allen Crumbaker, Billings, Mont., to Miss Lucille Jane Flaherty in Denver, June 14.

George R. Hamilton, Hartsburg, Ill., to Miss Ruby Lillian Owens of Highland, Ind., June 18.

Samuel Mickle Fox III Philadelphia, to Dr. Mary Alice Vann in Monroe, N. C., June 25.

Harry James Perlberg Jr., Baltimore, to Miss Toni Evelyn Aronsohn in New York, June 26.

Earl Kenneth Cantwell, Snyder, N. Y., to Miss Rita Roll of Buffalo, June 25.

# Deaths

**John Theron Wright** ⊕ Senior Surgeon, U. S. Public Health Service, Kensington, Md.; born in Reno, Nev., Feb. 14, 1912; McGill University Faculty of Medicine, Montreal, 1938; commissioned in the public health service in 1939 after interning at U. S. Marine hospitals in Norfolk, Va., and Galveston, Texas; formerly medical officer in charge at the Federal Reformatory in El Reno, Okla., and surgeon at the Federal Penitentiary at Leavenworth, Kansas; served on the Coast Guard cutter *Mojave* during World War II from July 1941 to May 1942; at one time assigned to U. S. Marine hospitals in Galveston, San Francisco and Kirkwood, Mo.; member of the American Public Health Association and the Washington section of the Society of Experimental Biology and Medicine; at the time of his death he was associated with the Microbiological Institute of the National Institutes of Health, Bethesda, Md., which he had joined in 1944 and where his work included studies in allergy, rabies virus, rabies vaccine and infectious hepatitis virus; died May 14, aged 37, of coronary occlusion.

**Walter Leon Angle** ⊕ East Stroudsburg, Pa.; Maryland Medical College, Baltimore, 1903; for many years school doctor; on the staff of the General Hospital of Monroe County; died June 10, aged 69, of coronary thrombosis.

**William Henry Beattie,** Utica, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1903; member of the American Academy of Ophthalmology and Otolaryngology; served on the staffs of the Masonic Soldiers and Sailors Memorial and St. Elizabeth hospitals; died April 19, aged 72, of cerebral thrombosis.

**Clarence Ward Bixler,** Longmont, Colo.; University of Colorado School of Medicine, Denver, 1907; member of the American Medical Association; died June 25, aged 70, of leukemia.

**Talma W. Buford,** Minter, Texas; Louisville (Ky.) Medical College, 1898; member of the American Medical Association; served as vice president of the Texas Association for Mental Hygiene; died in Paris June 2, aged 75, of cerebral hemorrhage.

**Court B. Chaffee,** Memphis, Tenn. (licensed in Tennessee in 1924); member of the American Medical Association; on the staff of St. Joseph's Hospital; died June 21, aged 63, of myocardial disease and cirrhosis of liver.

**Herbert Harvey Christensen** ⊕ Wausau, Wis.; Rush Medical College, Chicago, 1919; fellow of the American College of Surgeons; past president of the Marathon County Medical Society; served as secretary treasurer of the Ninth Councilor District Medical Society; on the staff of St. Mary's Hospital; for many years affiliated with Mount View Sanatorium; member of the American College of Chest Physicians and the American Trudeau Society; electrocuted June 20, aged 59, when his car hit a street light.

**Robert Miller Cooke,** Columbus, Ohio; Ohio Medical University, Columbus, 1907; died in the University Hospital April 25, aged 74.

**Percy Heilner Corson,** Plymouth Meeting, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1894; died June 27, aged 87, of acute cardiac failure due to chronic myocarditis.

**Charles Bartles Cortright,** Robles Del Rio, Calif.; Columbia University College of Physicians and Surgeons, New York, 1902; served on the staffs of Alta Bates and Herrick Memorial hospitals in Berkeley; died in Monterey, May 16, aged 71, of ruptured aortic aneurysm.

**Harry Gladstone Coulter,** New Wilmington, Pa., University of Pennsylvania School of Medicine, Philadelphia, 1919; served during World War I; died June 8, aged 60, of a heart attack following a fall.

**Jannes G. DeHond,** Milwaukee; Milwaukee Medical College, 1897; died May 18, aged 85, of heart disease.

**Frank Lowndes Dennis,** San Diego, Calif.; Southern Medical College, Atlanta, 1893; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; formerly practiced in Colorado Springs, Colo., where he was president of the El Paso County Medical Society and on the staffs of the Glockner-Penrose Hospital; served during World War I; died in the Mercy Hospital June 5, aged 77, of carcinoma of the liver.

**John Franklyn Detweiler,** Biloxi, Miss.; Long Island College Hospital, Brooklyn, 1886; Bellevue Hospital Medical College, New York, 1886; affiliated with the Biloxi Hospital; at one time president of the First National Bank of Wadsworth, Ohio; died June 7, aged 88, of coronary thrombosis.

**John Alexander Diamond,** Hammond, Wis.; Wisconsin College of Physicians and Surgeons, Milwaukee, 1906; member of the American Medical Association; died in Fairview Hospital, Minneapolis, June 4, aged 75.

**Alexander Goldman** ⊕ New York; Columbia University College of Physicians and Surgeons, New York, 1906; an associate fellow of the American Medical Association; member of the Association for the Study of Internal Secretions; formerly a pharmacist; founder and first president of Bronx Hospital and active head of its medical board for many years; died June 15, aged 77.

**Mary Linnie Hazlett,** Portland, Ore. (licensed in Tennessee in 1914); died June 8, aged 63.

**Harvey Theodore Herold,** Kearny, N. J.; University and Bellevue Hospital Medical College, New York, 1918; fellow of the American College of Surgeons; member of the American Association of Industrial Physicians and Surgeons; served during World War I; formerly on the staffs of the Hospital of St. Barnabas and for Women and Children and Presbyterian and City hospitals in Newark and the East Orange (N. J.) General Hospital; medical director of the Western Electric Company; died June 24, aged 53.

**Thomas Clark Hinkle,** Onaga, Kansas; Kansas Medical College, Medical Department of Washburn College, Topeka, 1904; member of the American Medical Association; minister of the Congregational Church; died May 13, aged 72, of coronary thrombosis.

**Paul Difrancesca Hippolitus** ⊕ Bridgeport, Conn.; Yale University School of Medicine, New Haven, 1912; on the staff of the Park City Hospital; died June 10, aged 59, of carcinoma of the pancreas.

**Frank C. Huth** ⊕ Cambridge, Ohio; University of Louisville (Ky.) Medical Department, 1893; medical superintendent and owner of St. Francis Hospital, where he died June 20, aged 83.

**Cecil McKee Jack** ⊕ Decatur, Ill.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1902; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; for many years president of the board of the Macon County Tuberculosis Sanatorium; affiliated with the Decatur and Macon County Hospital; served with selective service boards during World Wars I and II; died June 28, aged 72.

**Agnes Martyn Johnston,** Brooklyn; Boston University School of Medicine, 1903; died June 4, aged 71.

**Victor Barcroft Kieffer** ⊕ St. Louis; Barnes Medical College, St. Louis, 1905; at one time on the faculty of his alma mater; chief surgeon for the Missouri-Kansas Texas Railway Employees Hospital Association; on the staffs of St. John's and Missouri Baptist hospitals; died June 23, aged 68, of carcinoma.

**Walter B. King,** Tampa, Fla.; University of Georgia Medical Department, Augusta, 1909; died recently, aged 73, of cerebral hemorrhage.

**George Edmund Knauf,** Sheyboygan, Wis.; Rush Medical College, Chicago, 1904; member of the American Medical Association; at one time county physician; affiliated with St. Nicholas and Sheboygan Memorial hospitals; died April 29, aged 66, of carcinoma of the throat.

**George Francis Knue,** Indianapolis; Indiana University School of Medicine, Indianapolis, 1909; died in St. Vincent's Hospital June 25, aged 64, of general arteriosclerosis.

**Herman Koenig,** Santa Monica, Calif.; College of Physicians and Surgeons, medical department of Columbia College, New York, 1887; died June 22, aged 86, of heart disease.

**Joseph Thomas Kolbe,** Millville, N. J.; Georgetown University School of Medicine, Washington, D. C., 1935; certified by the National Board of Medical Examiners; member of the American Medical Association; served during World War II; died June 30, aged 37, of coronary thrombosis.

**Loren E. Lee,** Bonner Springs, Kansas; Kansas City Medical College, 1897; died in the Bethany Hospital, Kansas City, June 13, aged 75, of injuries received when the automobile in which he was driving was struck by a train.

**Jules Robert London** ⊕ Passaic, N. J.; University of Virginia Department of Medicine, Charlottesville, 1929; died in Seabright June 16, aged 45.

**William S. Loveland,** Joplin, Mo.; Curtis Physio-Medical Institute, Marion, Ind., 1893; member of the American Medical Association; on the staffs of St. John's Hospital and Freeman Hospital, where he died June 8, aged 81, of coronary thrombosis.

**William Linn McBride** ⊕ Corpus Christi, Texas; Rush Medical College, Chicago, 1901; specialist certified by the American Board of Dermatology and Syphilology; member of the American Dermatological Association, Inc.; formerly on the faculty of the University of Kansas School of Medicine in Kansas City, Mo.; served during World War I; died June 1, aged 73, of heart disease.

**Albert Anthony McCauley,** Boston; Harvard Medical School, Boston, 1897; for many years school physician in the Brighton district; served during World War I; died June 13, aged 79, of arteriosclerosis.

**Wylie Ernest McCleese,** Olive Hill, Ky.; University of Louisville School of Medicine, 1932; member of the American Medical Association; died June 16, aged 46.

**Francis Joseph McCormick** ⊕ Ithaca, N. Y.; Cornell University Medical College, New York, 1910; fellow of the American College of Surgeons; died in the Tompkins County Memorial Hospital June 30, aged 61, of emphysema and pulmonary fibrosis.

**John Robert McKenzie** ⊕ Watertown, Mass.; Harvard Medical School, Boston, 1894; for years a member of U. S. Pension Examiners; died in Baker Memorial of the Massachusetts General Hospital, Boston, recently, aged 81, of gastric ulcer with perforation and peritonitis, coronary arteriosclerotic heart disease and generalized arteriosclerosis.

**Joseph Johnston Macgowan,** Ashland, Miss.; Memphis (Tenn.) Hospital Medical College, 1890; member of the American Medical Association; died June 5, aged 80, of heart disease.

**Leonard E. Markin,** Glencoe, Ill.; Loyola University School of Medicine, Chicago, 1922; member of the American Medical Association; served during World War II; died in Wesley Memorial Hospital, Chicago, June 26, aged 51, of acute coronary occlusion.

**Earl Hugh Mayne** ⊕ Brooklyn; Bellevue Hospital Medical College, New York, 1893; fellow of the American College of Surgeons; an Associate Fellow of the American Medical Association; served as president of the Bay Ridge Medical Society; affiliated with Bay Ridge Hospital; died in Broadview General Hospital, Newport, Vt., June 9, aged 82, of coronary thrombosis.

**Charles Messick,** Topeka, Kan.; Kentucky School of Medicine, Louisville, 1888; died May 28, aged 83.

**Herbert Smith Miner,** Marshalltown, Iowa; Chicago Homeopathic Medical College, 1888; died in St. Thomas Mercy Hospital June 22, aged 91.

**Ignatius Joseph Murphy** ⊕ Minneapolis; University of Minnesota College of Medicine and Surgery, Minneapolis, 1909; member of the Radiological Society of North America; affiliated with Fairview Hospital in Minneapolis and St. John's Hospital in St. Paul; died in White Bear Lake, Minn., June 2, aged 65, of coronary thrombosis.

**James William O'Neil** ⊕ Springfield, Mass.; University of Pennsylvania School of Medicine, Philadelphia, 1911; formerly on the staff of Wesson Memorial Hospital, where he died May 22, aged 66.

**Eugene Orr** ⊕ Nashville, Tenn.; Vanderbilt University School of Medicine, Nashville, 1911; assistant professor of clinical otolaryngology at his alma mater; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; past president of the Nashville and Davidson County Academy of Ophthalmology and Otolaryngology; served during World War I; died May 18, aged 60, of chronic lymphatic leukemia.

**Ira Albert Pace,** Guide Rock, Neb.; University of Vermont College of Medicine, Burlington, 1891; past president of the Webster County Medical Society; served as a member of the school and library boards; president of the Guide Rock State Bank; died April 25, aged 80, of cerebral hemorrhage.

**Ernest Frederick Sappington** ⊕ Washington, D. C.; Hahnemann Medical College and Hospital of Philadelphia, 1905; died June 29, aged 68, of myocardial infarction and coronary thrombosis.

**Harold Charles Scheier,** New York; New York University College of Medicine, 1945; certified by the National Board of Medical Examiners; served during World War II; died June 29, aged 27.

**Otto Frederick Schussler,** Minneapolis; Minneapolis College of Physicians and Surgeons, 1905; member of the American Medical Association; died April 19, aged 75, of coronary disease and hypertension.

**Maximilian Jean Seidner** ⊕ Ogden, Utah; Chicago College of Medicine and Surgery, 1917; fellow of the American College of Surgeons and the International College of Surgeons; member of the American Trudeau Society; served during World War II; on the staff of the Thomas D. Dee Memorial Hospital; died in Worrall Hospital, Rochester, Minn., June 15, aged 55, of myocardial infarction and acute coronary occlusion.

**Alfred William Snedeker,** Staten Island, N. Y.; Cornell University Medical College, New York, 1924; member of the American Medical Association and the American Psychiatric Association; specialist certified by the American Board of Psychiatry and Neurology; superintendent of Richmond State Hospital, Richmond, Ind.; during World War II chief of the outpatient section of the neuropsychiatric division of Veterans Administration; died June 27, aged 51, of coronary occlusion.

**William David Stancil Jr.,** San Francisco; University of Colorado School of Medicine, Denver, 1944; member of the American Medical Association and the American Psychiatric Association; instructor in psychiatry at the Langley Porter Clinic, University of California Medical School; died in Palo Alto June 3, aged 29, of pneumonia.

**Milton J. Stern** ⊕ Lexington, Ky.; University and Bellevue Hospital Medical College, New York, 1911; specialist certified by the American Board of Ophthalmology; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; served during World War I; affiliated with St. Joseph and Good Samaritan hospitals; consultant in ophthalmology for the U. S. Public Health Service Hospital; died June 12, aged 59.

**Samuel Tietze,** Hartford, Conn.; Cornell University Medical College, New York, 1906; served during World War I; affiliated with Mount Sinai Hospital; died June 9, aged 65, of heart disease.

**Marshall Coleman Twitchell,** Burlington, Vt.; University of Vermont College of Medicine, Burlington, 1893; member of the American Medical Association; fellow of the American College of Surgeons; formerly on the faculty of his alma mater; on the staff of the Mary Fletcher Hospital, where he died June 15, aged 78, of heart disease.

**Irl Lloyd Waterman** ⊕ Amery, Wis.; University of Wisconsin Medical School, Madison, 1933; died at Nipigon, Ontario, Canada, June 4, aged 46, of coronary thrombosis.

**Ernest Augustus White** ⊕ Columbia Falls, Me.; Jefferson Medical College of Philadelphia, 1891; formerly on the board of examining surgeons for the bureau of pensions at Machias; at various times health officer of Columbia Falls and Addison; died suddenly, April 30, aged 82, of coronary occlusion.

**Jasper Newton White,** Texarkana, Texas; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1893; member of the American Medical Association; past president and secretary of the Bowie County Medical Society; formerly member of the State Eclectic Medical Examining Board; served the Michael Meagher Hospital, Texarkana, Ark., in various capacities; died in St. Michael's Hospital, Texarkana, Ark., May 17, aged 83, of acute myocardial failure.

**Joseph Meade White** ⊕ Major, U. S. Army, retired, Poolesville, Md.; College of Physicians and Surgeons, Baltimore, 1897; veteran of the Spanish-American War and World War I; entered the medical corps of the U. S. Army in 1920; retired Sept. 30, 1935 for disability in line of duty; died May 12, aged 77, of coronary thrombosis.

**Ellis Warner Willhelmy,** Kansas City, Mo.; University of Kansas School of Medicine, Kansas City, 1923; assistant professor of medicine at his alma mater; fellow of the American College of Physicians; past president of the Kansas City Academy of Medicine; served during World Wars I and II; on the staffs of St. Mary's Hospital and St. Luke's Hospital, where he died May 5, aged 50, of carcinoma of the pancreas.

**Cunningham Wilson,** Birmingham, Ala.; University of Pennsylvania Department of Medicine, Philadelphia, 1884; member of the American Medical Association; fellow of the American College of Surgeons; served on the county board of education; for many years chief of staff of St. Vincent's Hospital; died June 15, aged 89.

**George Emanuel Winter,** New York; Long Island College Hospital, Brooklyn, 1911; died in Yonkers June 7, aged 64, of pulmonary tuberculosis.

**John Baker Younger,** Leesville, La.; University of Tennessee College of Medicine, Memphis, 1927; member of the American Medical Association; died May 31, aged 49.

### Nationalized Medicine

It is difficult to define the state that exists at the moment between the doctors and the Minister of Health. It is not open warfare, but certainly it is not peace. With a large part of the profession the mood is one of smoldering discontent. The Minister passed his Amending Bill through the House of Commons by dint of the large majority of party supporters that he can always count on. The scope of the bill was confined to two matters, on both of which promises had been already made early in the dispute: the settlement of terms of partnerships arranged under the new act and an undertaking to the effect that, without further legislation, the present act could not be read to make the doctor a whole time paid servant of the state.

An important amendment from the opposition benches, allowing the prescriptions of private doctors to be dispensed at state expense, as are the prescriptions of doctors serving under the national health scheme, was defeated. Mr. Bevan has always opposed this principle; whether legally, under the clauses of the act, or not, may soon be settled by a test case in a court of law. This penalizing of the patients of doctors practicing outside the act, who, although they pay weekly for health services, do not get their medicines free as do the patients of National Health Service doctors, constitutes a sore point and may yet prove a big factor in the Minister's undoing. At the conclusion of the debate Mr. Bevan disclosed his fear that, if this privilege were recognized, the present 4 per cent of citizens who had not signed on lists of National Health Service doctors would probably increase and so sabotage the act.

In the Conservative Party's statement of policy, just issued, this question of parity of both types of patients is made a plank in the party's platform. The reference to Tory policy in respect of the health scheme is significant. It runs as follows:

"The nation has been warned by the Socialist Chancellor of the Exchequer that unless there is economy in the use of the Health Services some special charge or tax may have to be imposed. Conservatives share this anxiety about the maladministration and lack of foresight displayed by the Minister of Health and any Government may find itself forced to establish priorities based on need and urgency. We shall, therefore, see that the large sums of money spent on these Services yield their full value.

"The Health Services depend in the end upon the efficiency and goodwill of the family doctor. A Conservative Government would strengthen his position by restoring his freedom to practice anywhere and by offering a weighted capitation fee would give further security to doctors, particularly those in rural areas, with small lists. We shall allow an appeal against dismissal to go to the High Court instead of to the Minister.

"The scheme is intended to be comprehensive and any part of it should be available to any member of the public. We shall, therefore, allow private patients to obtain free of charge drugs prescribed by their doctor on a parity with people in the State scheme.

"By lack of forethought and bad administration the scheme has seriously damaged the valuable School Dental Service. Conservatives will restore the priority in staff and treatment for this service, and see that the needs of school-children, infants and expectant mothers are met first and fully.

"Much needs to be done to ensure that the hospital service is fully equipped and extended to meet all needs but this is more than can be accomplished in the lifetime of one Parliament at a time of great economic difficulty. There must, therefore be priorities. A Conservative Government will give first place to the re-opening of beds and the improvement of conditions for the nursing staff.

"As a result of the new legislation there is now no statutory duty on hospitals to admit the acutely sick. A Conservative Government will place on all hospitals within the Health Scheme a statutory duty to admit such patients, subject to proper safeguards.

"There are some hospitals associated with religious bodies and other voluntary organizations who wish to stay out of the scheme in order to preserve their special associations. A Conservative Government would be prepared to reconsider the cases of such hospitals as were not allowed to remain independent. But in general the former voluntary hospitals would be retained in the Scheme."

The position of the dentists under the new Service remains anomalous, the cost of the service to the nation being fantastic by comparison with the health care in general. In the case of the opticians the waste is grotesque, or would be if it were not that the country is so near bankruptcy. The following is an extract from a letter by the matron of a nursing home: "I went to see an old lady who lives in the Drapers Almhouses at M———. At the age of 87 she has just had five new pairs of spectacles. They were pressed upon her by the optician. She has spectacles for indoors, outdoors, reading, a special pair for playing the piano, a pair of bifocals and is to have still another pair to wear if she gets headaches"—which might well happen as the result of an anxiety state.

## ITALY

*(From Our Regular Correspondent)*

FLORENCE, June 30, 1949.

### Incomplete Rotation of Proximal Colon

At the Tuscan-Umbrian Society of Surgery, Professor Ricci discussed the mesenterium commune with incomplete rotation of the proximal colon. Nine patients were operated on at St. John's Hospital (Ospedale di S. Giovanni di Dio) in Florence. The first case was described by Professor Cavina, director and surgeon of the hospital in 1928; the other patients were observed among 9,362 laparotomies carried out in the last twenty years.

Professor Ricci stated that this condition should not be considered a disease entity, but that it may cause functional gastroduodenal disturbances (of pseudoulcerous type) or intestinal disturbances (constipation, tenderness about the right iliac fossa). Occasionally it may be associated with organic lesions (gastroduodenal ulcers, appendicitis). In other instances, as in 4 of the patients observed by the speaker, the abnormality contributed to occlusive phenomena, particularly volvulus of the cecum.

Professor Ricci expressed the belief that appendectomy in some instances may not have been indicated as only the anomaly of the intestine may have been responsible for the disturbance. This may be true also in other situations.

Professor Ricci advised a complete roentgenologic examination of the digestive tract prior to any abdominal intervention whenever possible to enable one to gain knowledge of the exact topography of the viscera.

According to the speaker the number of instances of such anomalies in world medical writings was about 200 at the end of 1947.

## PRURITUS ANI ET VULVAE DUE TO ALLERGY

*To the Editor:*—Skin testing with regard to contactant injury pertinent to pruritus ani et vulvae has received the condemnation of Dr. H. Hailey (Hailey, H.: Pruritus Ani et Vulvae, J. A. M. A. **139:** 837 [March 26] 1949) and the approbation of Dr. A. H. Rowe (Pruritus Ani et Vulvae Due to Allergy, correspondence, J. A. M. A. **140:** 644 [June 18] 1949). When contactant irritation is suspected, as it is in most cases of pruritus ani et vulvae, the effort of the practitioner (in contradistinction, perhaps, to the medical scientist) is to keep possibly irritant substances off the affected regions and to obtain the cure not by doing something to the patient but by inducing the patient not to do something harmful to himself. Soap, toilet articles and medicines are the common causes of contact dermatitis of the anogenital region. Rather than doing skin tests with them, the evidently simple thing to do is to dispense with all of them. Water can be trusted as noninjurious, to be allowed both for cleansing and for applications (cold) to allay itching. Petrolatum can be trusted as almost always noninjurious, to be allowed for its soothing and protective effects. The patient and the practitioner (in contradistinction, again, to the medical scientist) do not care which of the things that did touch the skin irritated it; skin tests are in such instances a waste of time, money and effort. Admitting the usefulness of patch tests in some circumstances and in the pursuit of science, I (Sutton, R. L., Jr.: Contact Dermatitis: Simplification of Therapy and of the Search for Causes, *J. Missouri State M. A.* **44:** 481-484 [July] 1947; Contact Dermatitis: Practical Management and Identification of Cause Without Patch Testing, *Arch. Dermat. & Syph.* **59:** 36-44 [Jan.] 1949; Handbook of Diseases of the Skin, St. Louis, The C. V. Mosby Company, 1949, p. 91) have tried in several essays to convey the facts of their relative inutility and the past, or passing, overestimation of their significance.

Richard L. Sutton Jr., M.D., Kansas City, Mo.

## TWINS WITH PEPTIC ULCERS

*To the Editor:*—The study of twins is of great value in providing information concerning the respective importance of hereditary predisposition and environmental influences in disease in man. The results of the use of this method have shown a hereditary predisposition to tuberculosis, diabetes and tumor formation and a high, medium or low intelligence quotient.

There is some a priori evidence showing a hereditary predisposition for peptic ulcer. Only 6 cases of the occurrence of peptic ulcer in the one or both of monozygous or dizygous twins have been reported in the readily accessible literature. Since twins are born in 1 of 86 births and identical twins in 1 of 344 births and the general incidence of ulcer is 5 to 10 per cent, there should be plenty of material available.

I should like to ask physicians to cooperate in assembling such material by sending me reports of cases in which one or both twins have peptic ulcer, together with the following data: (1) the site of the ulcer, (2) the age of onset of ulcer, (3) the type of twins (monovular or diovular), (4) the sex of the twins, (5) the date of birth of the twins, and (6) the number and age of the brothers and sisters and the absence or presence of ulcer in each.

A. C. Ivy, M.D.
1853 West Polk Street, Chicago 12.

## INCIDENCE OF UNDULANT FEVER

*To the Editor:*—In a letter to the Editor in The Journal, May. 28, 1949, Dr. Frederick Stenn reported the incidence of undulant fever among 100 patients observed in private practice from the stockyards district of Chicago. He observed only 1 person with a positive reaction to an agglutination test and 1 patient with a history of brucellosis.

The agglutination test cannot be relied on as the only means for the detection of brucellosis. Several reports have been published indicating the decided variation in the results of the test obtained in different laboratories (Carpenter, C. M., and Boak, R. A.: The Significance of Brucella Abortus Agglutinins in Human Serum, *J. Immunol.* **17** [July] 1929. Eisele, C. W.; McCullough, N. B., and Beal, G. A.: Discrepancies in the Agglutination Test for Brucellosis as Performed with Various Antigens and as Reported from Different Laboratories, *J. Lab. & Clin. Med.* **32,** 7 [July] 1947).

The intradermal test is a far more dependable procedure for the detection of sensitivity to Brucella. A positive reaction to an intradermal test, however, does not differentiate immunity from active infection, but it is more specific than the result of an agglutination test. Therefore, the reaction to a skin test should be correlated with the results of the agglutination test. In addition, such information should be interpreted only in the light of the patient's illness after exclusion of other factors which might cause a similar syndrome.

Charles M. Carpenter, M.D., Los Angeles.

# Medical Motion Pictures

## FILM REVIEWS

**Endotracheal Anesthesia.** 16 mm., color, sound, 800 feet (1 reel), showing time twenty-five minutes. Prepared under the direction of Charles F. McCuskey, M.D. Produced in 1948-1949 by Billie Burke Productions, Hollywood. Procurable on loan from E. R. Squibb & Sons, 745 Fifth Avenue, New York 22.

Introductory and closing remarks are made by Dr. McCuskey, who stresses that atraumatic laryngoscopy and endotracheal anesthesia are accomplished only by experience and a thorough knowledge of the physiologic and anatomic principles involved. This film attempts only to present a few of the basic requirements for endotracheal anesthesia. The necessity for a deep plane of anesthesia before attempting laryngoscopy is stressed, and the role of various agents and methods in obtaining this plane is briefly discussed and demonstrated.

Specific apparatus for endotracheal intubation is presented, including laryngoscopes, endotracheal tubes and cuffs. A valuable part of this film is the demonstration on the sagittal cross section of a fresh cadaver of the introduction of an endotracheal catheter. The use of a laryngoscope for photography developed by Dr. Glenn Potter of Los Angeles makes an excellent addition to this production; this phase might well have been expanded to include more demonstrations under direct vision.

The advantages of the application of this method in various types of surgery are briefly demonstrated and discussed. The need for the judicious use of endotracheal intubation if intercostal paralysis occurs during the intravenous use of curare is stressed. A statement that paralysis of the intercostal muscles with curare may be necessary to accomplish a difficult ligation of a patent ductus arteriosus might be open to question. Also, the statement that thoracic surgery owes its advances to endotracheal anesthesia might be misleading unless further clarified, since numerous successful intrathoracic operations have been performed without this method. Success depends on one's keeping the lumen of the endotracheal catheter, or air passages, patent and providing sufficient oxygen under satisfactory intermittent pressures to maintain normal physiologic function of the heart and lungs and prevent hypoxia or fatal anoxia. Adequate blood replacement and oxygen therapy are important in advancing thoracic surgery.

Even though the aim of this film is to present only a few of the basic requirements for endotracheal anesthesia, valuable additions might have included discussion of the need for maintaining a patent lumen of the endotracheal tube by the use of catheter suction; view of the thoracic activity that must result when manual pressure is exerted on the breathing bag during resuscitation; demonstration of the protection of the teeth, and a brief presentation of the possible complications and the methods of their avoidance or management. Such brief additions would enhance the value of this outstanding teaching film.

The authors wisely conclude that endotracheal anesthesia is not an innocuous procedure, especially in the hands of the inexperienced, and elaborating on this briefly might prevent the occurrence of complications and disasters in the hands of the insufficiently informed. This film is recommended for showing to anesthesiologists, surgeons, residents, medical students and the general medical profession. The photography is excellent.

---

# Council on Medical Education and Hospitals

## APPROVAL OF THE AMERICAN BOARD OF PROCTOLOGY

At a recent meeting, the Council on Medical Education and Hospitals, on the recommendation of the Advisory Board for Medical Specialties, voted to approve the American Board of Proctology. This board is the eighteenth examining board in the specialties to be approved by the Council. Until Dec. 31, 1954, the board will grant two types of certificates, one in anorectal surgery and one in colon surgery. After Jan. 1, 1955, the board will issue only one certificate, covering both anorectal and colon surgery. Prior to the establishment of the American Board of Proctology, certification in proctology was carried on by the American Board of Surgery acting in conjunction with the Central Certifying Committee in Proctology.

The first meeting of the new board at which candidates may present themselves for examination is being planned for November. Information concerning the examination may be obtained from the secretary-general. The president of the board is Dr. Curtice Rosser, Dallas, Texas, and the secretary-general, Dr. Louis A. Buie, 102-110 Second Avenue S.W., Rochester, Minn.

Donald G. Anderson, M.D., *Secretary*.

# Medical Examinations and Licensure

## COMING EXAMINATIONS AND MEETINGS

### NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: *Parts I and II.* Various Centers. Sept. 12-14. Exec. Sec., Mr. E. S. Elwood, 225 S. 15th St., Philadelphia 2.

### EXAMINING BOARDS IN SPECIALTIES

American Board of Anesthesiology, Inc. *Oral.* Denver, Oct. 16-20. Sec., Dr. Curtiss B. Hickcox, 745 Fifth Ave., New York 27.

American Board of Dermatology and Syphilology, Inc.: *Written.* Various Centers, Sept. 15. *Oral.* Cincinnati, Oct. 21-23. Sec., Dr. George M. Lewis, 66 East 66th St., New York 21.

American Board of Internal Medicine: *Written.* Oct. 17. Asst. Sec.-Treas. Dr. W. A. Werrell, 1 Main St., Madison 3, Wis.

American Board of Neurological Surgery: *Oral.* Chicago, June 3. Final date for filing applications is Jan. 1. Sec., Dr. W. J. German, 789 Howard Ave., New Haven.

American Board of Obstetrics and Gynecology, Inc. *Part I.* Various Centers. Feb. 3. I [illegible] is Nov. 5. Sec., Dr. Paul Titus, 1015 H[illegible]

American Board of [illegible] ct. 15-19; Boston; April. Sec., Dr. Edwin B. Dunphy, 56 Ivie Rd., Cape Cottage, Maine.

American Board of Orthopaedic Surgery. *Part II,* New York City, Feb. 9-10. Address: Sec.-Treas., Dr. Harold A. Sofield, Room 1856, 122 S. Michigan Ave., Chicago.

American Board of Otolaryngology: Chicago, Oct. 4-7. Sec., Dr. D. M. Lierle, University Hospitals, Iowa City.

American Board of Pathology: Chicago, Oct. 7-8. Final date for filing application is Sept. 1. Sec., Dr. Robert A. Moore, 507 Euclid Ave., St. Louis.

American Board of Pediatrics: *Oral.* Cleveland, Sept. 16-18; New York City, Oct. 21-23; Chicago, Dec. 9-11. Sec., Dr. John McK. Mitchell, 6 Cushman Road, Rosemont, Pa.

American Board of Plastic Surgery: Examinations are given in June and November of each year in the home town of applicants. Sec.-Treas., Dr. Louis T. Byars, 400 Metropolitan Bldg., St. Louis, Mo.

American Board of Preventive Medicine and Public Health: *Parts I and II.* New York, Oct. 22-24. Sec., Dr. Ernest L. Stebbins, 615 N. Wolfe St., Baltimore.

American Board of Proctology: November. Sec., Dr. Louis A. Buie, 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Psychiatry and Neurology, Inc. *Special Examination.* Chicago, Oct. 24-25. December, New York City. Final date for filing applications is Sept. 15. Sec., Dr. F. J. Braceland, 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Radiology: *Oral.* Cincinnati, Sept. 28-Oct. 2. Sec., Dr. B. R. Kirklin, 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Surgery: *Written.* Various Centers, October 26. Sec., Dr. J. Stewart Rodman, 225 S. 15th St., Philadelphia.

American Board of Urology: *Written.* December. *Oral and Clinical.* Chicago, Feb. 11-15. Final date for receipt of case histories is Sept. 1, 1949. Sec., Dr. Harry Culver, 7935 Sunnyside Road, Minneapolis 18.

### BOARDS OF MEDICAL EXAMINERS

Alaska: * Juneau, Sept. 6. Sec., Dr. W. M. Whitehead, Box 140, Juneau.

Alabama: *Examination.* Montgomery, June 27-29. Sec., Dr. D. G. Gill, 519 Dexter Avenue, Montgomery.

Arkansas: * *Examination.* Little Rock, Nov. 3-4. Sec., Dr. Joe Verser, Harrisburg. *Eclectic.* Little Rock, Nov. 3. Sec., Dr. Clarence H. Young, 1415 Main St., Little Rock.

District of Columbia: * *Examination.* Washington, Nov. 14-15. Sec., Dr. G. C. Ruhland, 4130 E. Municipal Bldg., Washington.

Florida: *Examination.* Jacksonville, Nov. 27-29. Sec., Dr. Frank D. Gray, 12 N. Rosalind Ave., Orlando.

Georgia: *Examination.* Atlanta, Oct. 11-12. *Reciprocity.* Atlanta, Oct. 13. Sec., Mr. R. C. Coleman, 111 State Capitol, Atlanta 3.

Guam: *Endorsement.* Agana, Last Friday of each month. Sec., Capt. C. K. Youngkin, Dept. of Public Health, Guam, % F.P.O., San Francisco.

Illinois: Chicago, Oct. 4-6. Supt. of Registration, Mr. Fred W. Ruegg, Capitol Bldg., Springfield.

Indiana: *Examination.* Indianapolis, June. Sec., Dr. Paul R. Tindall, 1138 K. of P. Bldg., Indianapolis.

Iowa: *Examination.* Des Moines, Dec. 5-7. *Reciprocity.* Des Moines, Sept. 5, Oct. 3, Nov. 7, Dec. 5. Sec., Dr. M. A. Royal, 506 Fleming Bldg., Des Moines.

Kansas: Topeka, Dec. 8-9. Sec., Dr. J. F. Hassig, 905 N. Seventh St., Kansas City.

Maryland: *Examination.* Baltimore, Dec. 13-16. Sec., Dr. Lewis P. Gundry, 1215 Cathedral St., Baltimore 1. *Homeopathic. Examination.* Baltimore, Dec. 13-14. Sec., Dr. John A. Evans, 612 West 40th St., Baltimore.

Minnesota: * Oct. 18-19. Sec., Dr. Julian F. Du Bois, 230 Lowry Medical Arts Bldg., St. Paul 2.

Mississippi: *Reciprocity.* Jackson, December. Sec., Dr. Felix J. Underwood, State Board of Health, Jackson 113.

Montana: Helena, Oct. 3-5. Sec., Dr. Otto G. Klein, First National Bank Bldg., Helena.

Nevada: Carson City, Nov. 7. Sec., Dr. George H. Ross, 112 N. Curry St., Carson City.

New Hampshire: Concord, Sept. 8-9. Sec., Dr. J. S. Wheeler, 107 State House, Concord.

New Jersey: Oct. 18-21. Sec., Dr. E. S. Hallinger, 28 W. State St., Trenton.

New Mexico: * Santa Fe, Oct. 10-11. Sec., Dr. Charles J. McGoey, Coronado Bldg., Santa Fe.

New York: *Examination.* New York, Albany, Syracuse and Buffalo, Oct. 4-7. Sec., Dr. Jacob L. Lochner Jr., 23 S. Pearl St., Albany 7.

North Carolina: *Endorsement.* Asheville, Oct. 17. Sec., Dr. Ivan Proctor, 226 Hillsboro Street, Raleigh.

Ohio: *Examination.* Columbus, December. *Endorsement.* Oct. 2. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

Puerto Rico: San Juan, Sept. 6-10. Sec., Dr. Luis Cueto Coll, Box 3717, Santurce.

South Carolina: *Examination.* Columbia, Nov. 8-9. *Reciprocity.* First Monday of every month. Sec., Dr. N. B. Heyward, 1329 Blanding St., Columbia.

Tennessee: *Examination.* Memphis, Sept. 28-29. Sec., Dr. H. W. Qualls, 1635 Exchange Bldg., Memphis 3.

Virginia: *Examination.* Richmond, Dec. 2-3. *Reciprocity.* Richmond, Dec. 1. Sec., Dr. K. D. Graves, 631 First St., S.W., Roanoke.

Wisconsin: * *Examination.* Madison, Jan. 10-12. Sec., Dr. C. A. Dawson, River Falls.

Wyoming: Cheyenne, Oct. 3. Sec., Dr. Franklin D. Yoder, Capitol Bldg., Cheyenne.

---

* Basic Science Certificate required.

### BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Alaska: Juneau, Aug. 28. Sec., Dr. C. Earl Albrecht, Box 1931, Juneau.

Arizona: *Examination.* Tucson, Sept. 20. Sec., Mr. Francis A. Roy, Science Hall, University of Arizona, Tucson.

Arkansas: *Examination.* Little Rock, Oct. 4. Sec., Mr. L. E. Gebauer, 1002 Donaghey Bldg., Little Rock.

Colorado: *Examination.* Denver, Sept. 14-15. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver 3.

District of Columbia: Washington, Oct. 24-25. Sec., Dr. G. C. Ruhland, 413C [illegible]

Florida: *E*[illegible] ec., Mr. M. W. Emmel, University of [illegible]

Michigan: [illegible] Arbor, Oct. 14-15. Sec., Miss Eloise Le[illegible] 15.

Minnesota: [illegible] 4-5. Sec., Dr. Raymond N. Bieter, 105 [illegible] nesota, Minneapolis.

Nebraska: [illegible] rector, Bureau of Examining Boards, Mr. Oscar F. Humble, Room 1009, State Capitol Bldg., Lincoln 9.

Oregon: Portland, Sept. 10 and Dec. 3. Sec., Mr. Charles D. Byrne, State Board of Higher Education, Eugene.

South Dakota: Vermillion, Dec. 2-3. Sec., Dr. Gregg M. Evans, 310 E. 15th St., Yankton.

Wisconsin: Milwaukee, Sept. 24 and Dec 3. Sec., Prof. W. H. Barber, Ripon College, Ripon.

# Current Medical Literature

## AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1938 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

### American Heart Journal, St. Louis

**37**:321-480 (March) 1949

Unipolar Electrocardiographic Leads: Effects Produced by Eliminating Resistors Between Limb Electrodes and Central Terminal. J. M. Bryant, F. D. Johnston and F. N. Wilson.—p. 321.
*Neutralization of Anticoagulant Effects of Heparin with Protamine (Salmine). T. W. Parkin and W. F. Kvale.—p. 333.
Comparison of Precordial Electrocardiograms Obtained with CR, CL, CF and V Leads. M. Dolgin, S. Grau and L. N. Katz.—p. 343.
*Neosynephrine in Treatment of Paroxysmal Supraventricular Tachycardia. W. B. Youmans, M. J. Goodman and J. Gould.—p. 359.
VII. Correlation of Electrocardiographic and Pathologic Findings in Lateral Infarction. G. B. Myers, H. A. Klein and B. E. Stofer. —p. 374.
Effect of Potassium on Downward T Waves of Precordial Leads of Normal Children. E. Goldberger, M. J. Pokress and R. Stein. —p. 418.
Auricular Paroxysmal Tachycardia in Association with Myocardial Infarction. J. M. Askey.—p. 425.

**Neutralization of Anticoagulant Effects of Heparin.**—Parkin and Kvale found that 1.5 mg. of salmine sulfate neutralized 1 mg. of heparin in vitro. When salmine sulfate was administered in large doses to guinea pigs, rabbits and dogs, it was found to have toxic effects, but when small doses, such as 1.0 mg. per kilogram of body weight, were administered, toxic effects were not noted. Salmine neutralized the anticoagulant effect of intravenous injections of heparin into dogs. When heparin in Pitkin's menstruum was injected intramuscularly into dogs, the elevated coagulation time returned to normal temporarily after the intravenous injection of salmine. The authors also report studies of 10 persons who consented to undergo tests with salmine sulfate. They found that in human subjects the intravenous injection of 40 to 50 mg. of salmine sulfate neutralized promptly the anticoagulant effect of 50 mg. of heparin; when salmine sulfate was administered slowly in these doses it did not produce any reactions.

**Neosynephrine in Tachycardia.**—According to Youmans and associates, neosynephrine differs from epinephrine in that the molecule has a hydrogen atom instead of the hydroxyl group in the para position on the benzene ring. In spite of their similarity chemically, the cardiovascular effects of the two drugs are different. In a preliminary paper the authors had reported the efficacy of neosynephrine in reverting paroxysmal supraventricular tachycardia to normal rhythm. They now present data on the use of neosynephrine in the treatment of nineteen attacks of paroxysmal supraventricular tachycardia. The drug produced reversion to the normal rhythm in seventeen attacks in 7 patients. It failed in 2 cases in which the attacks developed after major surgical procedures. Neosynephrine restores the normal sinus rhythm within thirty-five to seventy seconds after rapid intravenous injection in most cases of paroxysmal supraventricular tachycardia. The reversion of the supraventricular tachycardia is attributable to reflex cardiac inhibition elicited by the rapid rise in pressure in the carotid sinuses and aortic arch. The rise in pressure occurs as a result of the vasoconstriction produced by neosynephrine. Presumably any vasoconstrictor compound which acts quickly and briefly, and which has little or no direct stimulating action on the cardiac conducting system, would revert paroxysmal supraventricular tachycardia. Neosynephrine reverted paroxysmal supraventricular tachycardia in most cases when the systolic pressure reached a level of 160 mm. of mercury or less. In occasional cases reversion was produced with neosynephrine nly when the systolic pressure was elevated to levels which might be considered too high for safety. In the typical case the rise in systolic blood pressure is proportional to the dose of neosynephrine, and the maximum dose to be used is determined by the maximum rise in pressure which is considered safe for the individual patient. The initial dose should not exceed 0.5 mg., and any subsequent dose is selected on the basis of the pressor response to the initial dose. Most attacks were reverted by 1.0 mg. or less. These studies suggest that intravenous injection of neosynephrine, or some other rapid-acting vasopressor substance, will prove to be the treatment of choice in selected cases of paroxysmal supraventricular tachycardia.

### American Journal of Clinical Pathology, Baltimore

**19**:201-300 (March) 1949

*Actinomycosis: Pathologic and Bacteriologic Study of Twenty-One Fatal Cases. L. A. Weed and A. H. Baggenstoss.—p. 201.
Simple Direct Method for Electron Microscopy of Peripheral Blood Cells. J. W. Rebuck.—p. 217.
*Value of Beryllium Determinations in Diagnosis of Berylliosis. F. R. Dutra, J. Cholak and D. M. Hubbard.—p. 229.
Needle Aspiration in Diagnosis of Lung Carcinoma: Report of Experience with Seventy-Five Aspirations. E. Y. Gledhill, J. B. Spriggs and C. H. Binford.—p. 235.

**Actinomycosis.**—Weed and Baggenstoss report pathologic and bacteriologic features of 35 cases in which diagnosis was actinomycosis at necropsy. The organism Actinomyces bovis could be demonstrated in histologic sections with reasonable certainty in only 21, with considerable doubt in 3 and not at all in 11. Two of the 11 cases had decidedly different gross and microscopic features, and the observations were suggestive of nocardiosis. Nocardia was isolated in pure culture from 1 of these. In at least 13 of the 21 cases showing A. bovis, it was possible to demonstrate microscopic evidence of mixed infection. The probable clinical significance of the organisms associated with A. bovis was reflected in the presence of renal involvement in 12 of 16 cases (pyelonephritis and abscess formation) and nonactinomycotic brain abscesses in 5 cases. Evidence from the study of fixed tissues indicated considerable variation in the detailed structure of colonies presumed to be A. bovis. The variations included presence or absence of clubs, apparent fusion of clubs, staining reaction of clubs by the Brown-Gram technic, number of filaments, length of filaments, some of them being very short and more closely resembling diphtheroids, and compactness of the colonies, some of which showed almost diffuse growth. The sections also showed considerable variations in the amount of fibrosis. The presence of sulfur granules and the microscopic pattern, usually considered characteristic of actinomycosis, may be produced by organisms other than A. bovis. In many cases culture procedures may be necessary to make the differentiation. Much of the confusion concerning the diagnosis and treatment of what has heretofore been called "actinomycosis" may be eradicated if thorough bacteriologic studies are made of each case and if one uses the terms "Nocardia" for the aerobic form of the organism and "nocardiosis" for the resulting disease process, while the term "actinomycosis" should be reserved for the condition associated with the anaerobic organisms designated by Bergey as A. bovis.

**Beryllium Determination, Diagnostic of Berylliosis.**—Dutra and co-workers analyzed twenty-four hour specimens of the urine of 27 persons, 8 with acute beryllium pneumonitis and 19 with chronic pulmonary berylliosis, 14 of them with occupational and 5 with nonoccupational disease. Beryllium was isolated from the urine of most of these persons. The excretion of beryllium in the urine of persons suffering with either acute or chronic berylliosis varies from day to day, so that a few normal analytic results cannot be accepted as excluding berylliosis. It is possible that some patients with berylliosis do not excrete detectable amounts of beryllium at any time. Beryllium has been isolated from the urine of persons working in beryllium plants who had no symptoms of berylliosis, while some of these persons have had acute pulmonary berylliosis previously. The presence of beryllium in the urine of patients who lived in the neighborhood of beryllium plants or had dusted the clothing of husbands working in beryllium plants aided in the diagnosis of their disease. With a single exception, appreciable quantities of beryllium were recovered from the lungs of 7 persons who died of acute pulmonary berylliosis and of

10 persons who died of chronic pulmonary berylliosis. Beryllium was recovered from other tissues of the body in some of these cases. The diagnosis of acute or chronic pulmonary berylliosis may, in some cases, be supported by analysis of urine and by tissue analyses for beryllium.

## American Journal of Diseases of Children, Chicago

Beneficial Effect of Measles on Nephrosis: Report of 3 Cases. E. H. Meizlik and Anna-Mary Carpenter.—p. 83.

**Reticuloendothelial Granulomatosis.** — Blanchard and Boone report 2 cases of Hand-Schüller-Christian disease in a girl aged 6 months and in a boy aged 2½ years. The first infant showed dissemination of reticuloendothelial granulomas which, although presenting an occasional fatty droplet, failed to exhibit the characteristics of foam cells and cholesterol crystals. These so-called nonlipid granulomas were widely scattered, involving particularly the bone marrow, lymph nodes and spleen. The replacement of the blood-forming marrow tissue with the granulomas was responsible for the anemia, which was the most conspicuous clinical feature of the case. In the second case the most pronounced changes were present in the lungs, rib and skull. There were only minor infiltrations in the spleen, and the lymph nodes and the vertebral marrow were entirely free of them. The peculiar cutaneous infiltration is described in cases of so-called Letterer-Siwe disease. In the original biopsy specimen from the rib the histologic features were those of a nonlipid granuloma. At the autopsy several months later, sections from the same area showed extensive necrosis with acicular spaces, representing cholesterol crystals, and there was a massive infiltration of foam cells. A considerable quantity of hemosiderin pigment was also present, emphasizing the tendency for hemorrhages to occur in the lesions. The small miliary lesions in the spleen showed no tendency to hemorrhage. The features of these 2 cases of Hand-Schüller-Christian disease tend to support the hypothesis that the condition is a systemic reticuloendothelial granuloma of unknown origin. The presence of cholesterol in the lesions is a secondary occurrence, resulting from the ingestion of the lipid from the tissue fluids by the macrophages of the preformed granulomas. This theory is in accord with the well recognized fact that the value for serum cholesterol is normal in most cases. With the onset of necrosis in the lesion, this ingested cholesterol is liberated from the cells and is observed lying free in the lesions in crystalline form. From these sites it may be absorbed into the blood stream and give rise to transient hypercholesteremia.

**Toxic Diffuse Goiter.**—Topper reports 12 children, 5 boys and 7 girls between the ages of 3½ and 12 years with toxic diffuse goiter. The classic signs and symptoms of this disease, nervousness, tremor, tachycardia, exophthalmos and enlargement of the thyroid, were present in 11 of the patients. One patient did not show definite exophthalmos or tremor of the hands, but all the other symptoms mentioned were well pronounced. The basal metabolic rate was high in all patients, varying from + 24 per cent to + 52 per cent. Eight of these children were treated conservatively; 4 were subjected to thyroidectomy. These children had been observed for periods varying from three and one half years to twenty-five years. Of the 8 children treated medically, 1 died of an apparently unrelated condition ten years after the toxic diffuse goiter had been arrested. One child was lost track of after being well for three and one-half years. The other 6 were still under observation at the time of reporting. They were all well and leading normal lives. Of the 4 children treated surgically, 3 had occasional hypothyroidism, which responded readily to treatment. The fourth did not have any basal metabolism tests postoperatively. All 4 were well after a period of five to twelve years. One is tempted to speculate as to whether operation might have been avoided in these children. In childhood the thyroid is important for growth and development. During puberty there is a change in the endocrine activity, the gonads assuming greater importance and thyroid activity becoming more subdued. Any medical treatment that may cause even temporary remission of the symptoms of hyperthyroidism until puberty is established would be advantageous.

Mesenteric Cysts. R. L. Blackmun.—p. 371.

**Hidradenitis Suppurativa.** — According to Jackman and McQuarrie hidradenitis suppurativa is a chronic inflammatory disease of the skin and subcutaneous tissue affecting those areas in which the apocrine sweat glands are located, namely, the axillary, mammary, inguinal, genital and perianal regions. This condition is sometimes confused with pilonidal disease and anal fistula, and this may explain some of the so-called recurrent pilonidal cysts as well as recurrent anal fistulas. Although the perianal or the lower midsacrococcygeal region may be involved alone, there is usually also axillary adenitis either past or present. It may be necessary to ask the patient a direct question as to axillary involvement, since the process in that region may have been quiescent for years. The diagnosis of perianal manifestations of hidradenitis suppurativa is usually not difficult if the disease is thought of in case of what appears to be extensive anal fistula or pilonidal disease with many sinuses. An examination with the patient anesthetized may be necessary for a differential diagnosis between pilonidal cyst or anal fistula an hidradenitis suppurativa. Supporting the statement that hidradenitis suppurativa is much commoner than is generally appreciated is the fact that in an eight year period the condition w diagnosed at the Mayo Clinic in 388 patients. The axillas alone or in common with other sites were involved in 278 patients (alone in 187 cases), the mammary area alone or in combination with other sites in 32 patients, the groin in 92 and the perianal region in 125, or nearly one third of all patients. If conservative measures are ineffective, the involved perianal regions are excised en bloc. All sinuses and epithelial skin bridges should be explored and excised. Extensive denuded areas may require skin grafting.

**Addiction to Methadone.**—Isbell and co-workers state that after the invasion of Germany an intelligence team which investigated the German pharmaceutic industry found that chemists had developed a potent synthetic analgesic drug, 6-dimethylamino-4-4-diphenyl-3-heptanone which bore the serial number 10820. Investigation of the pharmacology of the drug in the United States showed that many of its actions resembled those of morphine. The authors present the results of studies on the liability of addiction to methadone. Methadone relieved the symptoms of abstinence from morphine. Methadone prevented the appearance of signs of physical dependence when substituted for morphine at a level of 1 mg. of methadone for each 4 mg. of the stabilization dose of morphine. Once substitution was effected, the dose of methadone could be rapidly reduced without signs of abstinence. After withdrawal of methadone, which had been substituted for morphine, a definite abstinence syndrome appeared which was slower in onset and milder than the syndrome of abstinence from morphine. Fifteen former morphine addicts were given methadone to produce addiction for twenty-eight to one hundred and eighty-six days. The psychologic changes and the general behavior of the subjects resembled those seen during morphine addiction. No serious toxic effects were noted. Fasting blood sugar content and intravenous dextrose tolerance tended to be low during addiction. Inflammation, induration and hypesthesia developed in the skin over the injection sites. Electroencephalographic patterns were slowed. The sedative action appeared to be cumulative. Systolic blood pressure, respiratory rates and pulse rates were depressed throughout addiction. Tolerance to the following effects of the drug developed as addiction progressed: pain-threshold-elevating action, sedative action, effect on the electroencephalogram, miotic action, depression of caloric intake and probably circulatory and respiratory actions. After abrupt withdrawal of methadone, an abstinence syndrome ensued. The average intensity of symptoms of abstinence was mild. The syndrome of abstinence from methadone differed from the morphine abstinence syndrome in that few signs of autonomic dysfunction were observed, the onset of abstinence was slower, the intensity was milder and the course was prolonged. Electroencephalograms did not return to normal for two to five days after withdrawal. The following evidence for habituation to methadone was observed: euphoria after repeated small doses (or single large doses), behavioristic and psychologic changes resembling those in morphine addiction, requests for increases in dosage during addiction, requests for methadone following addiction and preference for methadone over all other drugs. The same precautions should be observed in prescribing methadone as are used in prescribing morphine.

**Cholesterol and Atherosclerosis.**—According to Leary it is now generally accepted that crystalline ester cholesterol is constantly present in the active lesions of atherosclerosis. Illustrations of lesions of the aorta and of the coronary arteries of 5 men between the ages of 25 and 72 are presented. One of them died from obliterative pericarditis; 2 died of hypertensive heart disease and coronary sclerosis, while the remaining 2 were killed in accidents. This visual evidence, added to the data already published, indicates that atherosclerosis is a metabolic disease, that the relation of crystalline ester cholesterol to the lesions is as specific as is that of the tubercle bacillus in tuberculosis, that the focal character of the disease and the localization of its lesions are due to the crystalline esterification of excess cholesterol, in whatever form it is ingested, in the liver and the scavenger action of Kupffer's cells in removing that excess from liver cells, and that the excess cholesterol is transported into the circulation and deposited in the subendothelial layer of the arterial intima in regions where the cholesterophages can make contact with the arterial intima. In rabbits fed cholesterol the daily excess of cholesterol may lead to the production of massive acute lesions in which many layers of cholesterophages occur, with the cells enveloped in a delicate fibroblastic meshwork. These acute lesions are rare in man, but they were observed in 1 of the author's cases.

Congenital Dislocation of Hip. A. B. Gill.—p. 236.

***Effect of Heparin and Penicillin on Thrombophlebitis.***—The study presented by Rabinovitch and Pines was undertaken with the view of determining whether heparin alone or in combination with penicillin could bring about the solution of a clot in the presence of experimentally produced acute thrombophlebitis. The described experiments produced evidence to show that heparin is not effective in preventing the formation or causing the solution of an intravascular clot in the presence of acute thrombophlebitis. The combined administration of heparin and penicillin will prevent or cause the disappearance of a clot in a large number of subjects with experimentally produced acute thrombophlebitis.

**Mortality Rate in Appendectomy.**—McGraw reviewed the records of his clinic for the ten year period 1938 to 1947, inclusive. During the period in question 1,411 patients underwent operation at Henry Ford Hospital, Detroit, for acute appendicitis. The over-all mortality rate for the entire series was 0.64 per cent (9 deaths). Among the 46 patients who had abscesses drained there were 2 deaths, a mortality rate of 4.4 per cent. Among all 1,365 patients who underwent appendectomy there were 7 deaths, a ten year mortality rate of 0.5 per cent. All of the 9 deaths occurred among the 824 patients operated on during the first five year period, whereas during the last five years the mortality rate was zero. On the basis of a careful analysis of their cases the authors conclude that in spite of the indisputable help provided by the sulfonamide and antibiotic drugs, the prime factors in the elimination of death in acute appendicitis are: (1) the alertness with which symptoms and signs of the disease are recognized, (2) the promptness with which the patient is brought to operation after diagnosis and (3) the consistent use of an operative technic which is sound in conception and safe in detail for the difficult as well as for the uncomplicated case.

**Urethane in Multiple Myeloma.**—Loge and Rundles report 4 patients with multiple myeloma whom they treated with urethane for eight to ten weeks, with total doses of 120 to 290 Gm. The patients were observed over periods of seven to thirteen months. Striking benefit relating to all aspects of the disease was observed. Fever, skeletal pain and acute symptoms subsided after two to four weeks of therapy. In patients with severe anemia, immature granulocytes and nucleated red cells disappeared from the circulating blood and the blood values improved greatly over a period of several weeks. Abnormal plasma or "myeloma" cells decreased quantitatively in the bone marrow and underwent morphologic changes indicative of retarded or arrested growth. The serum protein abnormalities characteristic of multiple myeloma became less pronounced or disappeared, as did the albuminuria and Bence-Jones proteinuria. Serial roentgenograms of the skeleton showed no progression in the destructive lesions. There was little evidence of skeletal recalcification for four to six months after treatment. The long term results of urethane therapy in multiple myeloma, the liability to exacerbation, the effectiveness of subsequent courses of urethane therapy, the course of the associated renal disease and the extent of skeletal recalcification and repair are matters for further study.

**Carotid Sinus Syndrome.**—Evans reviews the records of 10 patients with carotid sinus syndrome. All had spontaneous syncope as well as vertigo, lightheadedness or staggering. Similar attacks could be reproduced in each by carotid sinus pressure. All appeared to have some carotid sinus dilatation—the right more than the left. Eight showed some sclerosis of the sinus. Eight had other cardiovascular signs or symptoms, including bradycardia, paroxysmal tachycardia, bothersome ectopic ventricular contractions, arteriosclerosis, atherosclerosis, arteriolar sclerosis, essential hypertension, temporary spontaneous hemiplegia, angina pectoris, acute coronary insufficiency, myocardial infarction and right and left bundle branch block. Four had coronary heart disease. The blood cholesterol was elevated in all the 6 patients in whom it was checked. The carotid sinus syndrome is primarily a disease of men in the upper age brackets. Fatigue and emotional states are important in the vagal as well as the cerebral type and may account, at least in part, for spontaneous variations in carotid sinus sensitivity. Psychotherapy is an important part of management. It is probable that pathologic changes in the wall of the sinus itself play a part in the picture. Associated abnormalities, such as Ménière's disease and the cardiovascular syndrome may make the diagnosis appear more difficult or appear more serious. Quinidine may reduce the number of seizures when ectopic beats are bothersome. More than one type of carotid sinus syncope may not only coexist, but one form may predominate at one time and another at another time.

**Streptomycin for Pertussis.**—Gordon and Almaden investigated the clinical effect of streptomycin against Hemophilus pertussis. It was the policy to admit to the isolation wards of the University Hospital at Little Rock, Ark., only cases of severe disease, usually with complications, or infants. Patients more than 8 months of age were admitted only if the disease was severe. Patients of the same type who had been admitted during the three years prior to the advent of streptomycin therapy were considered suitable for classification as control cases. The use of streptomycin in a dosage of 25 mg. per pound (50 mg. per kilogram) of body weight caused a definite and rapid improvement of 24 patients with severe pertussis. Comparison of the case fatality rate of the group of 28 controls and 27 treated patients revealed a statistically significant reduction in the treated group. The difference in the case fatality in the two groups is slightly more than three times the standard error. No significant improvement in the length of hospitalization was noted in the treated group as compared to the control group. The authors are of the opinion that streptomycin in conjunction with hyperimmune serum should be used on all critically ill hospitalized patients with whooping cough.

**Replacement Transfusion in Hemolytic Disease of the Newborn.**—Arnold treated icterus gravis for the past twenty years with multiple transfusions. Some of the infants were saved, but the infants with severe disease died. In 1942, when it became evident that the Rh factor was clinically important, the author started using Rh-negative blood and multiple transfusions. As the subtypes of Rh were determined and the Hr setup recognized he used homozygous Rh-positive blood in transfusing these rare Hr cases. With this regimen there was a definite improvement in results, but there was still much left to be desired. For the last two years he has been treating patients with severe hemolytic disease of the newborn by means of replacement transfusion. He used the umbilical vein method as described by Diamond the first twelve hours of life. When not using umbilical vein, he withdraws and replaces through the saphena magna vein. During 1948 the author has employed replacement transfusions in 16 patients and lost 3; the 3 losses were in attempts to save the lives of babies who were so severely damaged at birth as to preclude any kind of successful treatment. Care is taken at his hospital in all cases of erythroblastosis to correct existing dehydration, acidosis, hypoglycemia, hypocalcemia, hypoprothrombinemia, hypoproteinemia, anemia and anoxia. The author concludes that in all cases of severe erythroblastosis fetalis treatment should be with replacement transfusion. Only the mild conditions can be temporized with, and some of the apparently mild ones turn out to be severe enough to cause death or result in brain damage. In case of doubt as to the severity of the immunization, the baby should receive replacement transfusion.

**Vagotomy.**—Cameron and co-workers performed vagotomy for chronic peptic ulcer on 53 patients—50 men whose average age was 42.2 years and 3 women between the ages of 26 and 61 years. Vagotomy alone was carried out in 50 cases and was combined with gastroenterostomy in 3 cases. Forty-three patients had duodenal ulcers; 4 had gastric ulcers; 4 had marginal ulcers, and 2 patients proved postoperatively not to have had an ulcer, although both had roentgenographic indications, alleged bleeding episodes and symptoms suggesting peptic ulcer. Preoperative roentgenologic examination was performed in 47 patients, but a definite ulcer niche was demonstrated in only 12. The remainder had secondary indications, local tenderness, spasticity and deformity of the duodenal bulb. Transthoracic vagotomy was performed on 39 patients and abdominal vagotomy on 14. The transthoracic approach is preferred, because complete section of the vagi is essential and it is more easily accomplished by this route. One patient, who was admitted to the hospital with a clinical diagnosis of sublethal gastrointestinal bleeding, died eight hours after vagotomy. Postoperative follow-up of 45 patients, for twelve months in the majority of cases, revealed an average reduction of free hydrochloric acid secretion of 25 to 30 per cent in all specimens. Approximately 50 per cent reduction in average volume of night secretion and approximately 60 per cent reduction in average free acidity was noted. Forty-eight patients were immediately relieved of their unpleasant symptoms. They began almost immediately to follow unrestricted diets and gained weight, the average weight gain being about 13 pounds (6 Kg.). Fifteen patients had varying degrees of difficulty due to gastric retention, and 19 had diarrhea, which was severe only in the rare instances. The authors do not believe gastrointerostomy or pyloroplasty necessary where there is no preoperative gastric retention. In this short follow-up period they did not find it necessary to reoperate for gastric retention. Vagotomy alone can be expected to produce satisfactory results in approximately 90 per cent of cases of peptic ulcer.

**Food Requirements in the Arctic Regions.**—Orth says that precise information is sought on every phase of nutrition in the arctic regions, but the most important problem yet to be solved is that of man's water balance, which is made extremely difficult because of lack of fluids in the ration. Rations containing a considerable quantity of fluid will freeze and break the can or container. This is further enhanced by the fact that repeated freezing and thawing cause deterioration in taste, color and nutritive value, leading to reduced consumption. Canteens, even if filled at a water point, must be carried under the outer clothing to remain in a fluid state. Experiments disclosed that at —50 F. and at an altitude of approximately 600 feet, it took 200 cc. of fuel (gasoline) to melt enough snow to give 600 cc. of water. To melt ice would take less fuel, but it would take more than half a gallon of gasoline to get sufficient water for one man. The lack of sufficient fluids in the diet to maintain a positive water balance causes a change in disposition, sullenness, loss of appetite and chronic thirst, and then discipline begins to suffer. The final step is dehydration exhaustion, which may take as little as two days in the Arctic. Eating of snow and ice can delay this collapse, but the quantity of fluid obtainable in this way will not be great, because of the soreness of the mouth and the freezing of the lips and face incident to the constant cold applications. Required caloric intake under average conditions of physical activity is inversely proportional to temperature. Therefore, when prevailing temperatures in Arctic areas are subzero over periods of more than one week, the ration will be appropriately adjusted to provide a minimum of 4,400 calories per man per day. Experiments with troops in the cold winter months in Northern Canada and Alaska have indicated that an additional 15 to 25 per cent may be added to this figure under very adverse conditions and where heavy work is necessary.

**Chrysotherapy in Rheumatoid Arthritis.**—Friedman and Steinbrocker report the results of intensive and accelerated gold therapy in 18 patients with active rheumatoid arthritis in various stages. Sixteen patients were treated with aurothioglycanilide (lauron®), one with aurothioglucose (solganol-B oleosum®) and another with gold sodium thiomalate (myochrysine®). The dosage ranged from 0.9 to 10 Gm. administered over a period of six to eight weeks. The initial results, immediately after completion of the gold therapy, were as follows: complete remission of signs, 1 case; slight improvement, 2 cases, and no improvement, 15 cases. The patient who had a complete remission subsequently relapsed. Complete remission of symptoms and signs occurred in 2 other patients three and six months, respectively, after intensive chrysotherapy, and each had maintained that status for thirteen months at the time of reporting. These may be regarded as initial, delayed responses but may have been spontaneous. Large and accelerated doses of aurothioglycanilide did not exert impressive palliative or suppressive effects on rheumatoid arthritis. The use of the large doses of gold salts was not attended by an increased number of reactions.

**Results of Gastrectomy and Vagotomy.**—Warren and Meadows made an analysis of 120 operations performed for peptic ulceration. Their aim was to compare the results following subtotal gastrectomy and those following vagotomy. The mortality was 3.3 per cent among 89 subtotal gastrectomies and 0 among 28 vagotomies. Fifty-four patients who had subtotal gastrectomy and 22 patients who had vagotomy were examined four to twenty-four months after operation. There was 1 early recurrence of peptic ulceration in the former group, and there were 3 in the latter. The authors have confirmed the observations of Allen that the incidence of unfavorable side effects was quantitatively comparable in the two groups and have concluded with him that for the time being the use of vagotomy should be restricted to patients with anastomotic ulcer and to young patients without pyloric stenosis and with a presumably strong emotional phase of gastric secretion.

**Aureomycin.**—According to Herrell and Heilman attempts to study the aureomycin content of various body fluids in human beings have not been uniformly satisfactory. They describe the method in use in the laboratories of the Mayo Clinic, which has given adequately consistent results. Samples of serum or other body fluids for assay are taken at once to the laboratory and stored in the frozen state, in a chamber refrigerated with solid carbon dioxide. This is an essential part of the procedure, because aureomycin is unstable in the presence of serum or other body fluids when these samples are held at room temperature. Aureomycin is so labile that a delay of an hour or more in freezing the samples results in a serious fall in titer. Storage overnight in an ordinary electric refrigerator is attended by complete loss of active aureomycin in some samples. The laboratories use a simple tube dilution method employing thioglycollate broth and incubation overnight (sixteen hours) at 30 C. for assay. The test organism was Bacillus no. 5, a strain of Bacillus cereus used by Dornbush and Pelcak for assays of aureomycin. The authors used the described procedure for the study of the absorption, diffusion and excretion of aureomycin in human beings, to whom the antibiotic agent was administered in amounts which were regarded as therapeutically effective. After its absorption aureomycin diffuses readily into the cerebrospinal fluid in amounts which might be considered therapeutically effective. Studies of placental transmission indicate that aureomycin diffuses through the placenta and is available in the fetal circulation. When therapeutically effective amounts are present in the serum, diffusion occurs into the pleural fluid. Aureomycin appears to be concentrated in the normal hepatic system and is excreted in the bile. Large amounts of aureomycin are constantly excreted in the urine of patients receiving this antibiotic. It also has been found in the liver, kidney, spleen and lung.

**Angiocardiography in Congenital Heart Disease.**—Cooley and associates state that, with the advent of surgical therapy for congenital heart disease of the cyanotic type, the necessity for an exact diagnosis has become more important. They emphasize that no single diagnostic test will provide complete understanding of the anatomic and physiologic abnormalities in a patient with congenital cyanotic heart disease. The condition in many cases may be diagnosed on the basis of the history, physical examination and conventional roentgenographic examination, with emphasis on fluoroscopic study. Examination of the blood, including gas analysis, yields additional helpful information, while the more complex physiologic tests, including catheterization of the heart chambers, are often invaluable. Angiocardiography is an additional valuable weapon in this armamentarium, but for full realization of its value one should employ it, whenever possible, in conjunction with other studies. The authors have used angiocardiography in 75 patients. Usually they inject a 70 per cent solution of iodopyracet (diodrast®). A total of 140 injections have been made either into the basilic vein of the left arm or into the external jugular vein, without serious reactions. Histories are given of 9 patients in order to emphasize the advantages and shortcomings of the method in preoperative evaluation. Seven patients had the tetralogy of Fallot and 2 had a truncus arteriosus. All were subjected to operation, and in 1 instance postmortem studies were available. An overriding aorta could be demonstrated in all instances, as well as the position of the descending aorta. An interventricular septal defect may sometimes be directly demonstrated. Direct visualization of the pulmonary conus is so difficult that it is untrustworthy, but presumptive evidence of stenosis may often be obtained. It is not possible by angiocardiography alone to distinguish pulmonary atresia from a high degree of stenosis. The presence and character of the pulmonary arteries may be reliably determined. Failure to demonstrate the proximal portions of the pulmonary artery does not rule out the possibility of a successful anastomosis.

**Hiatal Diaphragmatic Hernia.**—Vinson reports 147 patients with protrusion of a portion of the stomach through the esophageal opening in the diaphragm. Twenty-one of these patients, 15 women and 6 men between the ages of 3 and 78, had herniation of the stomach through the esophageal hiatus beside the esophagus, the so-called paraesophageal type of hernia. One hundred and ten patients, 64 women and 46 men had a congenital shortening of the esophagus with a partially thoracic stomach. Sixteen patients, 9 women and 7 men, had a short esophagus and a portion of the stomach above the diaphragm but with definite cicatricial stricture at the junction of the esophagus and the herniated portion of the stomach. Flatulence, distress after meals, a feeling of fulness in the epigastrium and "acid indigestion," all of which may be intensified on the patient's lying down, may be noted in either type of hernia and may begin at any age. Epigastric pain with radiation substernally and down one or both arms is a frequent complaint. With ulceration that occurs at the junction of the esophagus and hernial sac in the short esophageal type of hernia bleeding often occurs. Dysphagia is the most frequent symptom but is rarely constant or severe enough to interfere with nutrition. The most satisfactory and the most accurate method for detection and differentiation of hiatal esophageal hernia is roentgenoscopic examination. In the absence of significant symptoms the condition rarely requires treatment. In the short esophageal type of hernia, dysphagia can almost always be completely relieved by passing dilating sounds over a guiding thread through the esophagus into the stomach. Spasm, pain and bleeding are also usually abolished by dilatation. Reduction of this kind of hernia by surgical measures is rarely indicated. Operative repair of the hernia is advisable when other symptoms than dysphagia are present in patients who have paraesophageal hernia and are in good physical condition.

**Plantar Warts.**—Pipkin and his co-workers treated 1,000 patients with a total of 1,744 plantar warts with a single dose of superficial roentgen rays. Shaving off the overlying hyperkeratotic epidermis and the surrounding keratotic collar is essential. The surface to be irradiated is meticulously outlined with ink. The window in the protective lead shield should be from 1 to 1.5 mm. in diameter larger than the lesion to be treated. The window is fitted exactly over the lesion, and the shield is pressed in place with glue and further fixed with adhesive tape. Warts of 6 mm. in diameter occurred most frequently in this series. To a wart of this size the average single and total dose of 2,040 r was delivered to a portal 7 mm. in diameter. The number of roentgens to be applied to the wart is solely dependent on its size: warts the diameter of which is 2 mm. or less are better treated by electrofulguration, liquid oxygen or some other destructive process; if the lesion is larger than 12.5 mm. it should not be treated with roentgen rays either. Six hundred and seventy of the patients had single lesions, and 330 had two or more verrucae distributed over the soles of one or both feet. There were twenty-four mother-daughter type warts. All patients were observed after treatment for periods of four months to twenty-one years. Of these, 910 (91 per cent) were cured and there were 90 (9 per cent) failures. The percentage of cures and failures varied from 85.1 to 100 and 14.9 to 0.0, respectively, depending on after-care, type and localization of plantar wart and whether or not the picture was complicated by previous scarring treatment or orthopedic problems. There were no unfortunate sequelae.

**Evaluation of Globin Insulin.**—The Sheppes state that modifications of insulin differ from the unmodified form in delaying, prolonging, reducing or intensifying the effects of the basic substance. The conclusions presented here were arrived at from an analysis of 386 diabetic patients currently under observation. One hundred twenty-five of these patients were being treated with the combination of globin and crystalline insulin. This combination provides the most efficient insulin control for the largest percentage of patients with severe and moderately severe diabetes. Globin insulin is a clear, stable solution with a moderately rapid effect which reaches its peak of intensity in eight to sixteen hours after injection, with progressively waning effect from the sixteenth to the twenty-fourth hour. It is relatively nonallergenic. When used alone, its action is somewhat similar to that of a 2:1 mixture of regular and protamine insulin. Its maximum activity is exerted during the period when insulin is most needed to control postprandial hyperglycemia. The total duration of effect is four to twenty-four hours, depending on the size of the dose. Nocturnal hypoglycemia is avoided, since the period of greatest intensity of action is from 4 p. m. to 8 p. m. If reactions occur at this time, they are easily combated or prevented by shifts in carbohydrate distribution. Extemporaneous insulin *mixtures* have been found to be of great advantage in the treatment of patients with moderately severe and severe diabetes. Globin insulin is well adapted to mix easily with other clear insulins. In such mixtures it retains its individual physical properties. For this reason, its effect is predictable with consequent ease of adjustment of dosage.

t

period of the disease. Spinal symptoms in "typical" cases begin abruptly; these occurred in 95 of the 100 cases. They are of great value in diagnosis but are variable with respect to type and severity. Two or more phases of the preparalytic stage may appear, and paralysis may spread in two or more stages. The spinal symptoms may subside before paralysis develops. In "typical" cases the onset of the preparalytic stage is vague and the symptoms of a prodromal stage may appear to merge into the preparalytic stage. An unusual amount of physical activity immediately preceded the preparalytic stage in 14 of the 100 cases. Complete physical rest in bed from the onset of the preparalytic stage greatly reduces the danger of severe paralysis. Severe physical activity at this stage is almost suicidal, while the continuance of even average physical activity is dangerous. The author feels that it should be possible to prevent many of *the cases of grave disease. Persons who are responsible for the* care of children should learn of the ways in which the disease can present. Sports meetings and special athletic contests should, if possible, be held outside the season for poliomyelitis. During an *epidemic exhausting physical activity should* be avoided, and all physical activity should be avoided during minor illnesses.

**Retropubic Prostatectomy.**—Millin and associates review observations in 757 cases of retropubic prostatectomy carried out by them during the years 1945 to 1948. Since the first report on this method in 1945 a number of modifications have been suggested, but the authors remain unconvinced that any major departure from the established technic has proved its worth. Their overwhelming preference for the retropubic approach is proved by the fact that it was used in 757 of a total of 919 cases of prostatic obstruction. They reserve the endoscopic route for minor subcervial lobes and the medium-sized glands in the very poor surgical risk. In the latter group, they are employing the open technic more and more. For a complete

**Lung Adenomas Induced by Urethane in Mice.**—Selbie and Thackray report studies on 75 male and 75 female CBA mice, 8 to 12 weeks old. They divided these mice into five groups of 30, each group containing an equal number of male and female mice. Urethane (ethyl carbamate) was administered to three groups, and the two other groups were kept under the same conditions so that the normal incidence of tumors could be estimated. Urethane was used in a 5 per cent solution in distilled water and was administered twice weekly by intraperitoneal injection in a dose of 0.2 cc. to the first group of mice, by stomach tube in a dose of 0.4 cc. to the second group and by nasal instillation of about 0.05 cc. to the third group. A considerable number of mice died from intercurrent infection. They were rejected in assessment of the results. Seven months from the beginning of the administration of urethane the surviving mice were killed. Tumors were found only in the lungs. Pulmonary adenomas were found in all of 24 CBA mice receiving the drug by intraperitoneal injection, in all of 9 CBA mice given the drug orally and in 4 of 20 CBA mice given the drug by intranasal instillation, whereas there was only 1 tumor in a comparable group of 51 CBA mice. From histologic examination of the adenomas in these mice and of tumors in early stages, it is concluded that the tumors arise from alveolar epithelium and are not preceded by pneumonic changes. It is suggested that urethane acts by lowering resistance to some tumor-stimulating influence, possibly a virus in the host.

**Thorotrast® Pyograms in Cerebral Abscess.**—Tutton and Shepherd use the term pyogram to describe the radiograms produced after instillation of thorotrast® (a colloidal suspension of thorium dioxide) into cerebral abscesses. Pyograms are valuable at any stage of a brain abscess. The first pictures always indicate the localization of the lesion and its relation to the burr hole through which it was tapped. The size of the shadow can be measured, and subsequent radiographs at frequent intervals will show whether the abscess is increasing in size and requires tapping again. As clinical signs of an enlarging abscess may be dangerously late in appearing, repeated pyograms are of great value in day to day evaluation of the course of the abscess. The authors report on 56 cases of intracranial abscesses in which pyographic studies were made. They describe the technic and the appearance of pyograms, the abscesses at special sites and the value of pyograms. The possibility of the radioactivity of thorotrast® must be considered with respect to its possible disadvantages in cerebral abscesses. Its dangers are negligible if the abscess is excised, but, when a thorotrast®-impregnated cicatrix is left, some reaction may occur. No reactions have been recorded in this series. The authors did not find a significantly high incidence of fits following the use of thorotrast® pyograms. More can be learned about brain abscesses from a systematic study of pyograms than has been possible in the past. The management of these cases is greatly assisted by the visual control which is possible by this method.

**Thymoma.**—Reid and Marcus present a historical survey of thymomas and an appraisal of their pathologic features. The clinical symptoms of a thymic tumor are few at first, and unless mass radiography is carried out their presence is not suspected until lymph node enlargement is seen or symptoms of intrathoracic pressure develop. In about half the cases symptoms of myasthenia gravis are present and lead to radiographic examination. The radiography shows a shadow which in the anteroposterior view occupies the mediastinum to one or other side of the heart shadow and in a lateral view occupies the superior mediastinum above the heart. It has to be differentiated from other mediastinal masses—especially lymphadenomas; cardiac aneurysm and pericardial cysts; mediastinal granulomas and teratomas, and congenital dilatation of the pulmonary artery. Surgical removal is the only sure method of cure. This may be difficult and dangerous, as the tumor does not remain encapsulated and may be adherent to large blood vessels and embedded in a vascular mass of adhesions. To date, 296 thymomas have been reported in the literature, 255 being malignant. Benign thymomas occur more commonly than malignant
thymomas in conjunction with [illegible] gravis. Thirty
thymomas associated with myast[illegible] have been removed

**Hypertension in Rats Following Choline Deficiency.**—Hartroft and Best produced a severe renal lesion in rats fed a diet deficient in choline. All the rats in which a severe degree of residual renal damage was produced by a short period of choline deficiency during early life later showed definite hypertension. The average blood pressure in this test series was 195 mm. of mercury as determined by arterial cannulization, while that of the controls was 118 mm. of mercury. The average weight of the hearts of the hypertensive animals was almost double that of the controls. The histologic picture of the arterioles of these animals was characteristic of advanced hypertension. When only a moderate degree of residual renal damage was produced by choline deficiency, the hypertension, cardiac hypertrophy and other pathologic changes were correspondingly less. There is no apparent immediate clinical application of these observations. The results suggest that further work may provide a simple way of consistently producing hypertension in an experimental animal by dietary means.

**Hypertension with Recovery After Nephrectomy.**—Maitland describes a case of severe hypertension with advanced retinitis and papilledema in a young woman of 20. The presenting symptom of headache, with vomiting and diplopia, suggested an intracranial lesion, but investigation revealed pathologic change in the left kidney as the likely cause. The removal of that organ with the adrenal produced a return of the blood pressure to normal in half an hour and a complete recovery from the retinal changes in a few weeks. This had been maintained at the time of writing. Reference is made to the significance of this result in relation to the experimental work of Goldblatt. It is also suggested that, if these cases can be recognized before the vascular changes elsewhere are permanent, nephrectomy offers the hope of a cure. The rarity of successful treatment in this type of case is mentioned, and stress is laid on the necessity for a most thorough investigation of the renal tract before surgical measures are advised. The author stresses the value of differential renal analysis in the general investigation of hypertensive patients.

**Paralytic Poliomyelitis.**—The paper by Russell is based on careful questioning of 100 patients (59 male and 41 female) who were convalescing from poliomyelitis and who were old enough to give a good account of their early symptoms. The prodromal stage, which consists of a brief and often slight illness lasting one or two days, is seen in less than half the cases, but neurologic symptoms occasionally appear even at this early stage. The preparalytic stage is the most critical period of the disease. Spinal symptoms in "typical" cases begin abruptly; these occurred in 95 of the 100 cases. They are of great value in diagnosis but are variable with respect to type and severity. Two or more phases of the preparalytic stage may appear, and paralysis may spread in two or more stages. The spinal symptoms may subside before paralysis develops. In "typical" cases the onset of the preparalytic stage is vague and the symptoms of a prodromal stage may appear to merge into the preparalytic stage. An unusual amount of physical activity immediately preceded the preparalytic stage in 14 of the 100 cases. Complete physical rest in bed from the onset of the preparalytic stage greatly reduces the danger of severe paralysis. Severe physical activity at this stage is almost suicidal, while the continuance of even average physical activity is dangerous. The author feels that it should be possible to prevent many of the cases of grave disease. Persons who are responsible for the care of children should learn of the ways in which the disease can present. Sports meetings and special athletic contests should, if possible, be held outside the season for poliomyelitis. During an epidemic exhausting physical activity should be avoided, and all physical activity should be avoided during minor illnesses.

**Retropubic Prostatectomy.**—Millin and associates review observations in 757 cases of retropubic prostatectomy carried out by them during the years 1945 to 1948. Since the first report on this method in 1945 a number of modifications have been suggested, but the authors remain unconvinced that any major departure from the established technic has proved its worth. Their overwhelming preference for the retropubic approach is proved by the fact that it was used in 757 of a total of 919 cases of prostatic obstruction. They reserve the endoscopic route for minor subcervial lobes and the medium-sized glands in the very poor surgical risk. In the latter group, they are employing the open technic more and more. For a complete description of the technic they refer to earlier reports, but they emphasize certain points and explain some misconceptions. They also discuss postoperative complications, such as pelvic cellulitis, osteitis pubis, suprapubic fistula, reactionary and secondary hemorrhages, postoperative stricture, incontinence, pulmonary embolus and funiculitis. On the basis of their experiences they conclude that the retropubic approach to the prostate conforms most nearly to the modern surgical ideal. Established prostatic obstruction should be relieved before renal impairment and advancing age add to the risk. Reasonably early intervention by the retropubic route offers a satisfactory functional result, with little risk and easy convalescence. The relief should be permanent, for the whole of the obstructing tissue is removed.

**Streptomycin in Nongonococcic Urethritis.**—According to Willcox treatment with penicillin or the sulfonamide drugs is not strikingly successful against nongonococcic urethritis and Reiter's disease, but many of the organisms—Bacillus coli and members of the pleuropneumonia-like group—which are thought to be possibly responsible for nongonococcic urethritis, though penicillin-resistant, are susceptible to streptomycin. The author employed single intramuscular injections of 0.2 to 1 Gm. of streptomycin in the treatment of 7 patients with nongonococcic urethritis. In 4 patients the signs were severe, with a profuse discharge and/or a grossly hazy urine, and in all of them improvement was immediate and spectacular, though in 2 cases there was a relapse which was successfully treated in the same way. Epididymitis was present in 1 case. In the 3 failures the condition before treatment was mild, with only a minimal discharge and clear urine with a few threads. The success of streptomycin therapy in this series was thus in proportion to the severity of the condition. Simple urethral and prostatic cultures were performed in all the cases, and no attempt was made to isolate pleuropneumonia-like organisms. Coliforms were obtained on culture in all 4 successful cases and in none of the 3 failures. The urethral Staphylococcus albus, which has often been reported in urethral cultures of patients with nongonococcic urethritis and is probably unconnected with the disease, proved resistant to streptomycin.

**March Hemoglobinuria.**—Lubran and Sakula report 3 cases of march hemoglobinuria in 2 private soldiers aged 18 years and in 1 aircraftman aged 20 admitted within about two weeks to one military hospital. The third patient had pronounced anemia; the symptoms of the other 2 patients conformed with the general description of the condition. The quantity of blood lost on each occasion of hemoglobinuria seldom exceeded 30 cc. Repeated losses of this order at short intervals were probably responsible for the anemia of the third patient. No spontaneous attacks of hemoglobinuria occurred during the patients' stay in the hospital, but attacks could be induced by their performing a standard exercise consisting of running and walking about 6 miles in one hour. The upright posture is essential for the development of this type of hemoglobinuria. Experiments showed that during an attack hemoglobinuria was associated with a rise in the plasma-hemoglobin level. Exercise in the upright position is associated with hemolysis, and the resulting rise in the plasma-hemoglobin level leads to the hemoglobinuria. It is suggested that in susceptible persons exercise causes the spleen to contract and expel a small number of highly fragile red cells into the blood stream. Hemoglobinuria disappeared immediately after the administration of large doses of ascorbic acid in 2 cases; in the third patient it disappeared in about three weeks. The ascorbic acid seems to lessen the amount of hemolysis or to diminish the sensitivity of the spleen. The therapeutic effect of ascorbic acid requires further study.

**Cystectomy in the Male.**—Romanus reviews observations on 49 male patients who underwent cystectomies at the Surgical Clinic of "Karolinska sjukhuset" during the years 1940 to 1947. Complications, both immediate and late, were less frequent in the 28 patients in whom the prostate and the seminal vesicles were removed than in those in whom they were left intact. Despite careful preoperative examination with urethrocystography and endoscopy as well as palpation before and during the operation, it is impossible to exclude pathologic changes in the seminal vesicles and the prostate. For this reason the completeness of removal will often be questionable when these organs are left in. The experiences of 21 patients who describe their sexual function after extirpation of the bladder show that, despite the removal of both the prostate and the seminal vesicles, the potentia coeundi may be normal, that is, the erection, the course of the coitus and orgasm are normal, but without ejaculation. As secondary complications may arise from apparently normal seminal vesicles and prostate left behind at operation, these organs should be removed in all cases of malignant vesical tumor. Only in cases of clearly benign changes in patients for whom it is particularly desirable to retain fertility should the prostate and the seminal vesicles be preserved.

**Gelatin and Polythene Film in Skull Defects.**—Busch and his associates point out that several fibrin preparations were produced in the course of the extensive investigations carried out during the recent war on the plasma protein fractions. These included a pliable and elastic substance that was used by some as a substitute for the dura mater. It was preferable to earlier substitutes consisting of fascia lata transplantata, gutta-percha, rubber or metal. There was no adherence between the fibrin film and the surrounding tissues, and while the film was slowly absorbed a new membrane of connective tissue formed, covering the defect and peripherally growing together with the normal dura mater. This fibrin film was difficult to obtain. The authors give an account of experiments with gelatin and polythene films. Gelatin films were found unsuitable as a dural substitute. Animal experiments confirmed that polythene film is nonabsorbable and that after subcutaneous, intraperitoneal, intrathoracic and other applications it causes little or no tissue reaction. When it was used as a dural substitute on animals and a large number of patients, the authors had the same good results as those obtained earlier by American workers. It was demonstrated in animal experiments and in clinical tests that polythene plates are excellent bone substitutes in skull defects, being easy to procure and to mold, causing no tissue changes and not interfering with subsequent roentgen examination.

New Experimental and Clinical Research on Treatment of Dyspnea with Pneumodilator Aerosols. R. Charlier.—p. 506.

**Vaccinal Encephalitis.**—Van Bogaert reports 16 cases of vaccinal encephalitis which occurred since 1931, 3 of them fatal, 64 cases of encephalomyelitis complicating chickenpox, 135 cases of disseminated encephalomyelitis occurring in the course of measles and 19 cases complicating scarlet fever. Of several concepts which have been suggested to explain the pathogenesis of encephalitis associated with eruptive diseases and of that following vaccination against smallpox, the author favors that by Glanzmann and Paul, according to whom the disseminated encephalitis which follows the exanthem is an anaphylactic phenomenon, an antigen-antibody reaction which may be observed in various eruptive diseases during the parallergic phase of the affected organism. The clinical and histopathologic analogy of the different types of encephalomyelitis may be explained easily, because they present only a form of hyperallergic reaction of the cerebral tissue, a common reaction which displays itself in different infections following a single mechanism with individual differences resulting from individual variations in sensitization. Each antigenic virus has its particular characteristics and imposes on the reaction a specific anatomicoclinical difference. The incubation period of the encephalitis varies from one exanthem to the other, but the comparison of vaccinal encephalitis with that associated with scarlet fever is suggestive. Besides individual variations, the rapidity of the formation of antibodies depends on the particularities of the septicemia and on the virulence of the infectious antigen. There is a definite immunologic relationship between the exanthem and the encephalitis. It is indicated by neurocutaneous alternation and dissociation of the hyperallergic reaction, the chronologic coincidence of the cutaneous and central hyperallergy, the specific immunity conferred by the encephalitis as well as by the exanthem, the predisposition of persons with a deficient cutaneous immunity and the histopathologic equivalence of the exanthem and of the encephalitis. The insufficiency of the pexic function of the skin brings the neuraxis, the other ectoderm desensitizer, into compensatory action in a person in whom the hematoencephalic barrier has been weakened by a previous lesion. Recent experimental work on nervous complications of revaccination also favors the concept of a neuronal allergy.

**Erythroblastemia of Fetus and Newborn Infant.**—Hubinont and Nameche report 1 case of hyperstimulation of the extramedullary erythropoiesis resulting in erythroblastemia with 25 per cent erythroblasts and 52 per cent nucleated red blood corpuscles in a premature newborn infant. Sudden death resulted from a meningeal hemorrhage after transfusion with Rh negative blood. Necropsy revealed volvulus of the small intestine. About 150 cc. of blood had extravasated in a pouch formed by the twisted loop of the bowel. This considerable amount of extravasated blood and the presence at birth of petechiae on the face and abdomen suggested a preexisting disturbance of coagulation. In a fetus delivered at term by cesarian section of a mother who for eight days presented continued hemorrhage due to placenta praevia, necropsy revealed the common signs of death resulting from sudden anoxemia, with considerable erythropoietic activity of the liver, which is abnormal in a fetus of this age. Neither in the newborn nor in the fetus was the secondary erythroblastosis due to hemolysis resulting from isoimmunization. In the case of the newborn infant the considerable internal hemorrhage represented an important diminution of the oxygen fixation power of the blood and a cause of anoxemia. Anoxemia should therefore be considered among the pathogenic factors of the erythropoietic reaction. In the case of the fetus the anoxemia played a primary part. The diminution of the placental hematosis by the separation and by the maternal anemia was the only responsible factor. In pathologic conditions of the newborn, erythroblastemia should be considered as a symptomatic factor of secondary importance.

*Hepatic Lesions in Pulmonary Tuberculosis: Anatomic Study of 150 Cases. O. C. Croxatto and F. M. Palermo.—p. 201.

**Hepatic Lesions in Pulmonary Tuberculosis.**—Croxatto and Palermo studied the livers of 150 persons of either sex who died from pulmonary tuberculosis. They found congestion of the liver with or without necrosis of liver cells in 67 cases, moderate fatty changes of liver cells in 32 congested livers and in 18 noncongested livers, fibrosis of the liver in 11 cases, typical cirrhosis in 2 cases and miliary tuberculosis of the liver in 57 cases. Congestion of the liver in pulmonary tuberculosis is caused by dilation of the right heart chambers, whereas *necrosis of liver cells is caused by local anoxemia and nutri*tional deficiencies. Pronounced fatty changes of liver cells are rare in pulmonary tuberculosis. Moderate fatty changes of liver cells in either congested or noncongested livers are more frequent in active forms of pulmonary or extrapulmonary tuberculosis of predominantly caseous type than in the same forms of tuberculosis of predominantly fibrous type. Necrosis of liver cells of a congested liver in the presence of moderate fatty degeneration of the liver cells is rare. Pulmonary tuberculosis may lead to the development of fibrosis of the liver, but it plays no role in the development of hepatic cirrhosis. Miliary tuberculosis *of the liver is a frequent complication of pulmonary* tuberculosis. The vena porta plays no role as a route for dissemination of the infection.

*"Chronic Cor Pulmonale:" Clinical and Roentgen Study of 150 Cases. M. Vaquero.—p. 763.

**"Chronic Cor Pulmonale."**—Vaquero reports a study on 150 patients between 50 and 70 years of age with chronic "cor pulmonale." Pulmonary sclerotic emphysema was present in all of the cases, and was complicated by chronic bronchitis in 69. The author states that it is possible to make an early diagnosis of chronic cor pulmonale before dilatation of the right ventricle and heart insufficiency are clinically established. Chronic cor pulmonale develops in three progressive stages manifested by *clinical symptoms, roentgenologic signs and electrocardiographic* changes. Early chronic pulmonary heart is manifested by dyspnea, cough and frequently cyanosis. The roentgen examination of the chest shows normal cardiovascular silhouette, intense positive cardiac response to the Müller and Valsalva tests for capacity volume of the heart, moderate enlargement of the branches of the pulmonary artery, pulmonary sclerotic emphysema and the causal pulmonary disease. The electrocardiogram shows a diphasic P wave in the V lead, tracings of the type $S_1$-$Q_3$, right axis deviation of QRS and P angles, normal negative values of the White and Bock index and possibly a negative T wave in the right precordial leads. In the advanced stage there are also cyanosis, moderate congestion of the jugular veins, moderate enlargement of the liver, increased venous tension and increased velocity of circulation. The roentgen changes of the heart show dilatation on the right, rotation of *the heart and enlargement of the middle* arch of the left profile of the heart. The electrocardiographic changes consist of auricular T wave in 2, 3 and VF leads, wider P wave, high in the 2, 3 and VF leads, tracings of the $S_1$, $S_2$ and $S_3$ type, right axis deviation of the QRS angle, small R wave in the precordial leads, tracings of either the R or RS type *in* $V_1$ *and in* $V_2$ leads, deep S wave up to $V_5$ and $V_6$, increased intrinsic deflection in $V_1$ and $V_2$ leads left deviation of the T angle, negative T wave in $V_1$ and $V_2$ leads, small QRS area and small gradient. Rapidly progressive cardiac insufficiency, edema and passive congestion of the pulmonary bases constitute the third and final stage of the disease. Several signs, including gallop rhythm, which are encountered during examination of the precordial region in patients in the third stage of the disease are also observable in the second stage.

*Rutin in Treatment of Pemphigus Foliaceus. J. Aleixo.—p. 361.

**Rutin in Treatment of Pemphigus Foliaceus.**—Aleixo administered rutin to 2 patients with pemphigus. The disease was of ten days' duration in 1 patient and of eight months' duration in the other. Rutin was given by mouth in daily doses of 80 mg. up to a total dose which varied between 0.08 Gm. in ten days and 0.16 Gm. in twenty days. The treatment resulted in disappearance of the bullae in the patient with a recent dermatosis. In the other patient, in whom the disease was more generalized and of longer duration, the older lesions regressed and new lesions did not appear.

Electrokymography. J. Schneider and F. G. Gillick.—p. 110.

**Nicotinic Acid (Niacin) Derivatives in Obliterating Endarteritis.**—The treatment described by Prusik consists of injections of compounds of nicotinic acid (niacin) exhibiting decided vasodilating effects. He employs a 3 per cent solution of triethanolamine of nicotinic acid for subcutaneous and intramuscular injections or a 1 per cent solution of the hydrochloride for intravenous injections. Good results were obtained with 20 or more injections in a total of 694 patients, who had disorders of the peripheral arteries, with or without gangrene. The injections greatly reduced the need for surgical treatment, particularly amputations of the lower extremities. Of 76 patients with gangrene resulting from Buerger's disease only 7 had to be operated on. The toxicity of the nicotinic acid preparations was slight.

*"Polyneuritic" Diseases after Treatment with Arsphenamine. F. Laubenthal.—p. 270.

**Clinical Aspects of Hepatogenic Ulcer.**—Jahn reports 10 cases which illustrate a relationship between ulceration in the stomach or the duodenum and disease of the liver. Hepatic disease precedes the development of the gastroduodenal ulceration. The type of hepatic disorder varies. Of the patients whose cases are reported, some had hepatic disorders without jaundice with known or unknown causation; others had infectious hepatitis, incipient cirrhosis, caused either by inflammatory lesions of the hepatic parenchyma or by chronic infection of the bile passages, and still others had impairment of the hepatic metabolism as the result of a growing neoplasm or senile cachexia. The clinical course and the roentgenologic aspects of the hepatogenic ulcers do not differ from those of other types of ulcer. In necropsies of 2 of the aforementioned patients extensive hemorrhagic erosions were discovered in addition to the ulcer. The course of healing of the hepatogenic ulcer is like that of other ulcers, except that there is a greater tendency to relapses when enlargement of the liver continues. Treatment of the liver by administration of large quantities of carbohydrates is an important factor in the control of the ulcer. Treatment with artificial fever makes it possible to interrupt the inhibited protein metabolism. This is usually followed by a rapid increase in weight.

**Variations of Leukocytes.**—Eilers and co-workers counted the leukocytes and made differential counts from blood smears of 11 patients with leukocytosis of various intensity and causes every three hours for twenty-four hours. These eleven day and night counts did not reveal a definite and uniform rhythm like that which had been demonstrated concerning the formation, maturation and release of erythrocytes. Considerable differences were observed in the counts from the pipets as well as from the smears for which the same blood had been used, and that in spite of their keeping the technic as exact and as uniform as possible. To determine the medium deviation of the single variation classes from the medium value, and herewith the extent of possible errors, statistical computations were based on total leukocyte counts and differential counts from the blood obtained from 3 additional patients, 2 men aged 47 and 55, respectively, with myeloid leukemia and 1 man aged 57 with chronic pneumonia and exudative pleuritis. These control series revealed that a standard regular twenty-four hour rhythm which would have been presumed according to the up-to-date knowledge of rhythmic cell segmentation and processes of growth cannot be demonstrated by the common clinical methods of evaluation of the white blood cell picture. The considerable deviation of the variations of the leukocytes from the medium value should be considered in clinical diagnosis and prognosis to judge whether the leukocytosis is increasing or subsiding. Even with 20 cell counts the medium value may have a deviation width of 3,200 cells, or of plus or minus 24 per cent; this indicates that the leukocytosis may be considered as subsiding only when the number of leukocytes are below this limit.

**"Polyneuritic" Diseases after Treatment with Arsphenamine.**—Laubenthal considers two groups of lesions of the peripheral nervous system occurring in syphilitic patients who had been treated with arsphenamine. Patients belonging to the first group may present headache, rise of temperature, pain in the arms and legs associated occasionally with erythema, urticaria and swelling of joints, occurring within a few minutes, several hours or several days after the arsphenamine injection, frequently after the first injection. The acute aspect of the disease suggests an allergy or idiosyncrasy similar to the susceptibility to iodine. As a rule the condition has a favorable course. Five patients, 4 men and 1 woman between the ages of 25 and 50, are reported who belonged to the second group with neurologic disturbances occurring within three to twelve weeks after the last injection of arsphenamine. There was a gradual onset with paresthesias preferentially of the lower extremities and later of the upper extremities; severe motor pareses with distal localization developed. There was a rapidly progressing atrophy of muscles, disturbances of circulation in the extremities, disturbances of sensibility with distal localization and "burning pain" similar to causalgia. The neurologic aspect corresponded with that of chronic arsenic poisoning. All 5 patients presented icterus, which developed during the treatment with arsphenamine, while erythema, urticaria, swelling of the joints and fever were absent. The course of the neurologic disturbances was protracted, but there was a tendency to improvement. The duration of the disease was several months to two years. The pathogenic importance of the disturbance of the metabolism of the liver for these severe myatrophic disturbances after the treatment with arsphenamine is emphasized.

Closing-In Phenomenon in Syndrome of Apraxia Due to Carbon Monoxide Poisoning. J. Ajuriaguerra, R. Zazzo and N. Granjon.—p. 1.

Diencephalic Attacks. C. I. Urechia.—p. 21.

*Phenomenon of Phantom Limb. B. Bornstein.—p. 32.

**Phantom Limb.**—Bornstein reports 22 cases of phantom limb in 19 men and 3 women between the ages of 13 and 72 years, in 16 of whom amputation was performed for trauma and in 6 for vascular disturbances. Six postwar cases of phantom limb in 3 men and 3 women of middle age are reported in whom amputation was performed for injuries caused by bursting shells. The author's observations confirm the opinion of others that 8 to 12 per cent of the amputees will have a sensation as of the amputated limb's still existing, and in the majority of them this sensation may start within a few days after the surgical intervention. The interpretation of the phantom limb is linked with the psychic existence of a corporeal image, which represents a final product not only of an arithmetical sum of the psychosomatic perceptions of the various sensorisensitive organs but also of the optic and kinesthetic perceptions. The existence of the phantom limb is more likely to occur in persons in whom optic perceptions predominate over the kinesthetic perceptions. The important psychic function which constitutes the existence of the corporeal scheme is localized in the nervous centers, probably in the parieto-occipital thalamic bundle. Electroshock treatment was instituted in 3 of the author's cases: in 1 patient, whose leg had been amputated and who had suffered severe phantom pain for seven years, the pain subsided after two treatments. In the second patient, whose forearm was amputated, the phantom pain disappeared after two treatments. The third amputee with a phantom limb was a morphine addict; when the drug was withheld an anxiety state developed for which shock treatment was instituted; the phantom pain disappeared after two treatments. In all 3 patients the phantom limb did not reappear during a follow-up period of one and a half years.

*Millin's Operation for Hypertrophy of Prostate. H. R. Bloch.—p. 62.
*Question of Citrate Toxicity with Citrated Blood; Second Report. M. Allgöwer and W. Reif.—p. 75.

**Millin's Retropubic Prostatectomy.**—Bloch performed Millin's retropubic prostatectomy on 21 patients between the ages of 59 and 82, 13 of whom had incomplete retention of urine and 8 chronic retention of urine. The retropubic drain was left in place for three days and the urethral catheter with continuous suction drainage of the bladder for six days. The majority of the patients were discharged on the fourteenth postoperative day. Seventeen patients made an uneventful recovery, 1 patient died and 4 patients had postoperative complications, such as hemorrhage, urinary fistula and infection of the space of Retzius. The advantage of the retropubic approach from the point of view of the patient consists in the absence of postoperative shock, the almost painless convalescence and the brief hospital period. In the author's experience the incidence of operative and postoperative complications did not exceed that after Freyer's operation. Complications will occur still less frequently with more practice, when the space of Retzius will be known to the last corner, for in general not the method but the surgeon is responsible for such complications. The advantages of Millin's method from the point of view of the surgeon are the anatomic neatness of the technic and the easy and clean after-treatment.

**Citrate Toxicity with Citrated Blood.**—Experiments carried out by Allgöwer and Reif on rabbits and human beings revealed a reduced phagocytosis of the blood neutrophils when tested with Eberthella coli after citrated blood transfusions and injections of isotonic solutions of sodium citrate. The inhibitory effect on the phagocytosis was still manifest eight hours after the infusion, but could not be demonstrated after twenty-four hours. There seems to be a relationship between the inhibitory effect and the administered dose on one side and the body weight of the receptor on the other side. The part played by the general condition of the receptor is still being investigated. The extent of this inhibitory effect and its duration in the receptor of larger doses of citrate suggest that it may be of practical importance with regard to the employment of tribasic sodium citrate as a stabilizer in transfusions. In normal persons experimented on, 1 Gm. of tribasic sodium citrate per 25 Kg. (55 pounds) of body weight was tolerated without any considerable damage to the leukocytes. This should be taken into account in the employment of large amounts of citrated blood.

Spontaneous Emphysema of Mediastinum. E. G. Fongi, O. Fustinoni and E. Marguery.—p. 431.

**Circulatory and Respiratory Functions in Constrictive Pericarditis.**—Taquini and his collaborators studied the circulatory and respiratory functions of 5 patients with constrictive pericarditis. The tests were repeated after surgical intervention in 3 patients. Venous pressure, cardiac output, oxygen consumption, pulmonary ventilation, alveolar air, vital capacity and residual air were determined under basal conditions. Before the operation the results showed an increase in the venous pressure, in the heart rate and in the difference of arteriovenous oxygen and a decrease in the systolic output and in the cardiac output. There was a reduction of the systolic output in 3 patients, due to limitation of diastolic ventricular filling. In the other 2 patients the analysis of the results led the authors to accept the existence of an inflow stasis and myocardial insufficiency. During rest, the increase in the heart rate partially or fully compensates the reduction in the systolic output, keeping the cardiac output within practically normal limits. Respiratory function showed a slight degree of pulmonary hyperventilation and low vital capacity. The tests repeated in 3 of the patients after surgical intervention showed an increase in systolic and cardiac output, with a decrease in the venous pressure, the heart rate and the difference of arteriovenous oxygen. There were no important changes in the respiratory function. Pulmonary ventilation showed no significant alteration in spite of the decided lowering of venous pressure.

*Case of Aspermia: Unusual Cause of Sterility in Man. L. I. Swaab.—p. 420.

**Paratyphoid Transmitted by Smoked Herring.**—Hemmes reports an outbreak of paratyphoid in which 123 cases occurred in seventeen different localities. Four of the cases had a fatal outcome. The outbreak could be traced to the eating of smoked herring, which was traced to a smoking establishment in which a worker had been ill but had continued to work. Examination of the feces and urine of this worker yielded Salmonella schottmülleri.

**Unusual Cause of Aspermia.**—Swaab stresses that aspermia is characterized by the total absence of ejaculate, whereas in azoospermia seminal fluid is produced but spermatozoa are absent or inactive. He presents the case of an otherwise healthy man who had aspermia. On ejaculation no sperm was produced, but after coitus the urine was found to contain spermatozoa. Ejaculation took place into the bladder as a result of a weakening of the vesical sphincter.

Surface-Active Invert Soaps Applied Intraperitoneally. S. S. Krook.—p. 318.

**Effect of Curare in Spastic and Related Conditions.**—Fifteen patients given treatment with curare were observed for ten to thirty weeks. Nearly all with spasticity in the lower extremities reported subjective improvement, and as a rule a change in the degree of spasticity was objectively noticeable. Thygesen and Christensen consider curare applicable especially in cases of spastic pain but also in attempts to improve the function of spastic extremities in cases with light paresis. The treatment should be prolonged. It is not a substitute for physical or orthopedic treatment but only a supplement to it, primarily to increase the availability of the musculature for physical treatment. The beginning dose in adults should be about 1.5 cc. purified chondrodendron tomentosum extract (intocostrin®) or 0.5 cc. tubocuran or tubarine. The optimal dose seems to be the dose that just causes transitory accommodation paresis and possibly light ptosis, given at three or four day intervals. In grave degrees of spasticity stronger doses are necessary and give only moderate relief.

**Treatment of Headache with Diluted Epinephrine Solutions.**—Fagerberg reports that of 18 patients with headache treated with intravenous injections of 1 cc. of epinephrine solution, 1:400,000 and in some instances 1:80,000 or 1:800,000, 11 showed decided improvement, in 2 the effect was doubtful and 5 were unchanged; 1 of the 2 patients with migraine was improved. The best results appeared in cases with more diffuse, indefinite disorder, sometimes a pressure and sometimes pronounced pain, localized in different parts of the head. The solutions were kept in sealed dark bottles under refrigeration. Tests by the fluorescent method for determination of epinephrine and biologic tests in isolated rabbit intestines showed that epinephrine solutions several weeks old were effective.

**Complications in Intraosseous Therapy.**—Hiertonn states that in sternal puncture and infusion there is danger of perforation of the sternum with injury to the heart or intrathoracic deposit of fluid. He cites 4 cases from the literature. In the first of 2 cases he reports, in a boy aged 3, operated on for congenital dislocation of the hip, two unsuccessful attempts at sternal puncture with a view to intraosseous therapy were followed by a new insertion in the manubrium; an aspiration test was performed and blood was infused. The boy died thirty minutes after the operation. Necropsy showed perforating channels through the sternum and the hemothorax; the sternum was only 6 mm. thick. In the second instance, in a boy aged 6, with osteomalacia, shock occurred after osteosynthesis of the hip (according to Küntscher). Treatment with sternal puncture and infusion of dextran and blood gave good results. Some days later there was a dull sound over the right lung and dyspnea was pronounced. After pleural puncture blood was aspirated. The child recovered. Perforation may have occurred during manipulation of the cannula during the blood transfusion, and the fragility of the bone may have contributed, as roentgen examination showed normal thickness of the sternum for the age.

Artificial Vaginal Cycle and Adrenal Secretion in Rats. G. Poumeau-Delille.—p. 247.

**Jennerian Vaccination.**—According to Ramon and coworkers there has occurred a recrudescence of postvaccinal encephalitis in France, Belgium, the United Kingdom and Holland in recent years. It is believed that the recrudescence of this as well as of other complications associated with the Jennerian vaccination is due to a considerable extent to an increased virulence of the Jennerian virus. The infectious power of the Jennerian virus may be increased by adventitious pathogenic microbes which have been observed frequently in the vaccinal pulp. Experiments carried out in horses, rabbits and in vitro demonstrated that by adding 0.02 to 0.05 of the commercial solution of formaldehyde to 100 cc. of the vaccinal pulp, the Jennerian virus can be transformed into an "anavirus," which causes the rapid development of antibodies in the serum of horses at the same titer as the fully virulent and not modified virus, destroying in vitro the infectious properties of the virus and protecting rabbits against the inoculation with the same virus. After treatment with formaldehyde the vaccinal liquid was subjected to temperatures varying from 15 to 20 C. for sixteen hours to six days. By this means all the adventitious microbes were eliminated from the vaccine. Certain samples of the vaccinal liquid proved to be practically sterile. By optional variation of the amount of formaldehyde added to the vaccinal liquid, of the temperature to which the latter may be exposed and of the duration of the effect of these two agents on the virus, a vaccine will be obtained, the employment of which will reduce or even eliminate the complications associated with Jennerian vaccination.

*Serologic Reaction as Aid to Diagnosis of Cancer: Statistical Results. R. Fontaine, M. Aron and P. Buck.—p. 227.

**Serologic Reaction Diagnostic of Cancer.**—Animal experiments previously reported by Aron showed that subcutaneous injections of filtrates of urine of patients with cancer caused characteristic changes in the adrenal cortex of rabbits but this reaction could not be produced in rabbits which had been given previously an injection of the blood of cancer patients. It appeared that the blood of patients with cancer may contain antibodies which in the presence of urinary "antigen" may cause flocculation. Fontaine and his co-workers demonstrated that the addition of a solution of urine extract of patients with various types of cancer to the blood serum which has been heated in the water bath to 55 C. for five days causes a flocculent precipitation much more pronounced than that caused in the blood serum which has not been heated. In the absence of cancer the flocculent precipitation in the heated serum is identical with that in the unheated serum. Aron's flocculation test was performed thirty-nine times in 34 patients with cancer; there were 34 positive reactions, 2 doubtful but rather positive reactions, 1 doubtful but rather negative reaction and 2 negative reactions. Thus in 85 per cent of the cases with cancer the reaction was positive. The test was performed in 66 patients who did not have cancer; there were 61 negative reactions, 2 doubtful reactions, 1 doubtful but rather positive reaction and 2 positive reactions. The reaction, therefore, was negative in 92 per cent of the cases without cancer. Aron's serologic reaction seems to give results which are superior to those obtained by any other method. The few erroneous reactions may have been due to the difficulty of certain readings or to insufficient observance of technical precautions.

**Urethane and Central Nervous System.**—Klima and Wengraf treated 25 patients with various diseases of the blood with urethane during the period August 1947 to May 1948. Therapeutic results were particularly satisfactory in patients with chronic myeloid leukemia, but 8 patients presented disturbances suggesting damage to the central nervous system: they were depressed and ready to cry or listless and finally completely apathetic. In addition to fatigue and exhaustion there was vertigo, headache, anxiety and tremor. These symptoms became manifest after the administration of 27 Gm. to 80 Gm. of urethane in doses of 3 to 4 Gm. per day. Three of the patients, 1 woman aged 43 with myeloid leukemia, 1 woman aged 54 with subacute, subleukemic lymphoblastosis and 1 man aged 48 with aleukemic lymphatic leukemia, died. Necropsy revealed macroscopic focal changes in the central nervous system, and microscopic examination of these areas demonstrated glial increase of cells particularly in the neighborhood of ganglion cells. Urethane exerts a toxic effect on the ganglion cell apparatus. In the authors' cases the considerable damage done to the brain and the spinal cord was manifested by disseminated foci. Clinical experience seems to suggest that the damage is reversible to a certain extent. Results with irradiation therapy were not inferior to those obtained with urethane.

**How Psychiatry Helps.** By Phillip Polatin, M.D., Associate Clinical Psychiatrist, New York State Psychiatric Institute, New York, and Ellen C. Philtine. With a foreword by Dr. Nolan D. C. Lewis. Cloth. Price, $3. Pp. 242. Harper & Brothers, 49 E. 33d St., New York 16, 1949.

This excellent book is written primarily for the public and should be especially helpful for patients and their families. The language is simple with a minimum of technical terminology. The major theme is an easily understandable description of the methods and principles underlying modern psychiatric therapies and the results which may be reasonably anticipated from their proper utilization. Although therapeutic optimism is expressed, a wholesome leavening of conservatism is apparent with recognition of the limitations of various types of treatments.

Only the first chapter deals with psychiatric philosophy and a delineation of the common types of psychiatric disturbances. Further discussions of etiologic and dynamic factors in symptom formation are occasionally used in case examples or woven into the description of various types of treatment, but an explanation of psychiatric therapeutic methods remains the primary objective. Practically all modern psychiatric therapies are discussed as fairly and extensively as a book of this length will permit. These include psychoanalysis, direct interview psychotherapy, psychobiologic distributive analysis and synthesis, narcotherapy and other chemical treatments, shock therapy and psychosurgery. A brief chapter covers the treatment of alcoholism, drug addiction, epilepsy and dementia paralytica. Also included are a short discussion of the principles of mental hygiene and a directory of agencies which supply information concerning psychiatric facilities.

The authors do not advocate a single doctrinal concept but recommend a broad and inclusive approach to the problems of psychiatric therapy. They are to be commended for their basic medical orientation and their acceptance of any type of treatment which benefits the patient and provides him with greater insight and better methods of meeting his personal difficulties. Not only is the book recommended for the layman but it would be profitable and easy reading for the busy practitioner.

**The Surgery of the Colon and Rectum.** By Sir Hugh Devine, M.S., F.R.C.S., F.R.A.C.S., Honorary Surgeon to Out-Patients Alfred Hospital, Melbourne. Cloth. Price, $12.50. Pp. 362, with 277 illustrations. Williams & Wilkins Co., Mt. Royal & Guilford Aves., Baltimore 2, 1948.

In the preface of this first edition of this brief book the authors state, ". . . the book is a general effort—diagnostic and operative—to improve the results of surgery of malignant disease of the colon and rectum." That portion of the book which pertains to this problem deals with the authors' experiences and is well done, although little which has not been written by others is included.

The book consists of 32 chapters on important topics. The first chapter is devoted to "Surgical Anatomy of the Colon and Rectum." It is instructive and comprehensive. Proctoscopic and sigmoidoscopic examination are included in this chapter. The description reveals a decided lack of knowledge of this important subject and is too brief to possess any value.

The second chapter, "Surgical Physiology of the Colon and Rectum," is fairly well done but is incomplete. The same opinion applies to chapter III, which deals with "General Diagnosis and Symptomatology of Diseases of the Colon" and chapters IV and VI, in which "The Diagnosis of Malignant Disease of the Proximal Colon" is discussed.

Chapters V, VII, VIII, IX, X, XII and XIII deal with "Innocent Diseases Involving both the Proximal and Distal Colon." The material is interesting and informative but all too brief.

Chronic ulcerative colitis is discussed in a few paragraphs of chapter XI, and the description of the sigmoidoscopic picture fits many types of inflammatory disease of the terminal portion of the colon. The authors state, ". . . surgical treatment of ulcerative colitis has not been satisfactory," and dismiss the complicated subject of medical treatment with this statement: "Medical treatment of chronic ulcerative colitis includes special forms of diet, the administration of vitamin C, the elimination of infection, the use of sensitized vaccines made from organisms cultured from the affected bowel and the use of special serum in certain cases." They then devote most of the remainder of chapter XI to surgical treatment, including a discussion of appendicostomy and a description of various types of enterostomy and colectomy. Chapter XVI, entitled "Operative Exposure of the Colon: Use of the Devine Operating Frame," is devoted to a description of the authors' retracting apparatus.

Figure 263 is purported to show "a fibroma prolapsed through the anus." The small tumor appears to the reviewer to be a hypertrophied papilla. Material on hemorrhoids, anal fistula and anal fissure is most incomplete and sketchy. The old-fashioned and discarded hard rubber tube with gauze wrapped around it is described, and surgical procedures are performed with the outmoded lithotomy position.

**Neurological Anatomy in Relation to Clinical Medicine.** By A. Brodal, Prosector of Anatomy, University of Oslo, Oslo. (Revision and translation of "Nevro-Anatomie," 1943.) Cloth. Price, $14.75. Pp. 496, with 94 illustrations. Oxford University Press, 114 5th Ave., New York 11; Amen House, Warwick Sq., London, E.C. 4; Johan Grundt Tanum Forlag, Oslo, 1948.

This is a "practical" neuroanatomy in the sense that its purpose is to relate neuroanatomy to clinical medicine rather than to serve as a descriptive text of an anatomic field. This approach also requires the introduction of as much physiologic as strictly anatomic material. Approaches of this sort pose a difficult task for an author. Physiology is a rapidly changing field and it is not surprising that Brodal's text, the original edition of which was prepared during the war years and in an area deprived of much of the new literature, should already be somewhat outdated. In this English edition the author has been able to introduce a certain amount of recent material, but an underlying earlier structure is still apparent. The author's choice of physiologic material was so sound fundamentally that as the text now stands additions rather than basic changes are presently required. Judgment is in fact the salient characteristic of Brodal's book. It is sound and the material is presented in a fresh and orderly manner with great clarity of thought and several rather penetrating presentations.

One is surprised to find that the cerebellum, a structure on which the author has done most of his research, in conjunction with his mentor, Jansen, is given rather cursory treatment, while some other subjects, which Brodal has obviously had to work up for the occasion, are handled more completely but, of course, in a much stiffer fashion.

The book is recommended for the clinician who is looking for something more reliable and well rounded than Fulton's Neurophysiology, more modern than Brock's Basis of Clinical Neurology and more comprehensive than Merritt, Mettler and Putnam's Fundamentals of Clinical Neurology. For a work which is almost devoid of illustrations the price—$14.75—seems fantastic. If the book does not have a wide sale in the United States the publisher and not the author should be blamed.

**The American Academy of Orthopaedic Surgeons Presents Lectures on Regional Orthopaedic Surgery and Fundamental Orthopaedic Problems. Number II. Selected from the Instructional Courses of the Fourteenth Annual Assembly, Chicago, January 25-30, 1947.** Editor, James E. M. Thomson, M.D. Associate Editor, Walter P. Blount, M.D., Chairman of the Instructional Section. Cloth. Price, $7.50. Pp. 255, with illustrations. J. W. Edwards, 300 John St., Ann Arbor, Mich., 1948.

This book, the second volume of Regional Orthopedic Surgery and Fundamental Orthopedic Problems, comprises some of the lectures delivered at the 1947 Annual Instructional Course sponsored by the American Academy of Orthopedic Surgeons. The opening lecture, dealing with the diagnosis, treatment and prognosis of primary malignant tumors of bone, is written in a clear and concise manner. A short article reiterating some of the most salient points in reconstruction of the hand is of special interest. Among the papers dealing with lesions in the cervical region, the controversial scalenus anticus syndrome is discussed from an anatomic point of view. Opinion has since crystallized, and the prolapsed cervical disk and costoclavicular syndrome have their staunch adherents. This section is followed by one dealing with low back pain—some of the surgical concepts will not find favor in every quarter. Three excellent lectures on congenital dislocation of the hip, by orthopedic surgeons eminent in this field, can be commended to all. The differential diagnosis in the treatment of some common lesions of the shoulder should be read with the lectures on this subject in the previous volume. They place this difficult problem on a simple basis, easy to understand and follow out in practice. At the historical dinner of the American Academy of Orthopedic Surgeons four interesting and entertaining papers were given dealing with the early years of orthopedic surgery in this country.

Each year the lectures from the instructional courses appear to be greatly improved over their predecessors. Much credit is due the American Academy of Orthopedic Surgeons for sponsoring these courses and for making them available.

**Tuberculosis in Childhood.** By Dorothy Stopford Price, M.D. With a chapter on Tuberculosis Orthopædic Lesions and Other Contributions by Henry F. MacAuley, M.Ch., F.R.C.S.I., Orthopædic Surgeon, Mater Misericordiæ Hospital, Dublin. Second edition. Cloth. Price, $7. Pp. 219, with 87 illustrations. Williams & Wilkins Co., Mt. Royal & Guilford Aves., Baltimore 2; John Wright & Sons, Ltd., 42-44, Triangle West, Bristol 8, England, 1948.

This second edition contains 219 pages. Its thirteen chapters touch on many phases of tuberculosis in childhood. In diagnosis, the author emphasizes the importance of the tuberculin test and states that it is an essential diagnostic aid in the detection of all forms of tuberculosis among children. It is the only possible method of detecting symptomless primary tuberculosis. She points out that in the adolescent and young adult the tuberculin test is becoming more valuable, as primary infection is more often postponed to these ages. Repeated tuberculin testing of nonreactors is regarded as necessary. The statement that primary tuberculous infection occurs at some time in the life history of every person does not apply to the United States, where in large areas not more than 5 to 8 per cent react to tuberculin at the age of 18 years.

The chapter on roentgen rays contains forty-three illustrations of pathologic specimens and roentgen reproductions. It is emphasized that from the roentgen ray shadow alone the etiology of the lesion cannot be determined. Price finds that in Dublin 50 per cent at least of the children who react to tuberculin have roentgenologic lesions demonstrable by the shadows they cast. This is a much higher figure than has been found in the United States, where many of the calcific deposits are the result of fungus infections and other nontuberculous conditions.

An excellent chapter is devoted to primary tuberculosis of the lungs, tuberculosis of the mediastinal glands and pleurisy. The acute reinfection forms of tuberculosis, such as miliary disease, meningitis and pneumonia, among children are discussed at some length.

Attention is called to the development of primary tuberculosis among adolescent persons. In the area where Dr. Price works, 50 per cent of the children are infected at the age of 14 years. She states that all the others must become infected; therefore half of all primary lesions develop in adults. The highest death incidence occurs in the 20 to 25 year age period. In several states in this country, the height of mortality is not reached until after the age of 60 years. As in this country, Dr. Price has found that the immediate prognosis in primary tuberculosis is good, but the ultimate prognosis in any given case may be unfavorable. Dr. Price believes that total eradication of tuberculosis may be achieved in years to come by the compulsory control of all persons with positive sputum and by the extermination of all tuberculous cattle. Chapters 12 and 13 are devoted to extrathoracic tuberculosis in children.

This is a good book. Several points of view which differ considerably from those held by tuberculosis workers in the United States are due largely to the much greater prevalence of tuberculosis in Dr. Price's field of activity.

**Pediatric Nursing.** By Gladys S. Benz, R.N., B.S., M.A., Associate Director, Union University School of Nursing, Albany, N. Y. Cloth. Price, $4. Pp. 638, with 119 illustrations. C. V. Mosby Co., 3207 Washington Blvd., St. Louis 3, 1948.

As knowledge accumulates regarding more effective therapeutic measures for the diseases of children, technics throughout the field of child care must necessarily undergo changes. So it is in the field of pediatric nursing.

This book covers the entire field of pediatric nursing, is up to date and thorough. Such new concepts in the care of children as self-demand feeding are explained in detail.

Chapters dealing with the history of the pediatric hospital, statistics on infant mortality and activity and safety programs as they affect child care, in addition to the usual chapters found in textbooks concerned with pediatric nursing, make this book a well rounded text.

**Atlas of Neuropathology.** By Wm. Blackwood, M.B., F.R.C.S.E., Assistant Pathologist, the National Hospital, Queen Square, London, T. C. Dodds, F.I.M.L.T., F.I.B.P., F.R.P.S., Laboratory Supervisor, Department of Pathology, University of Edinburgh, and J. C. Sommerville, A.I.M.L.T. Foreword by Professor A. Murray Drennan, M.D., F.R.C.P.E., F.R.S.E., Professor of Pathology, University of Edinburgh. Cloth. Price, $9. Pp. 199, with 262 illustrations. The Williams & Wilkins Co., Mt. Royal & Guilford Aves., Baltimore 2, 1949.

This is an introductory text designed for the beginner in neuropathology. Its purpose is to provide illustrative material to students and others who do not have an adequate variety of specimens readily available. The majority of the illustrations are of gross specimens, although there is a fair number of photomicrographs. The text is limited to a few brief statements regarding each condition dealt with and the figures chosen to illustrate it. The disorders described and illustrated are limited to the common neurologic conditions. Rare diseases, minor variations and controversial subjects are not presented.

In general the illustrations are well chosen and well reproduced. Only a few are open to criticism. In one or two instances the photographs selected depict an atypical example of the condition under discussion. In a book designed for the novice and one so limited in textual matter this is unfortunate. The most outstanding examples of this are figure 127, which shows the spinal cord in a case of subacute combined degeneration (posterolateral sclerosis) with severe degeneration in the posterior columns and almost none in the lateral ones; figure 211, which the authors recognize to be an atypical example of an oligodendroglioma, and figure 205, which is probably an example of a pineoblastoma rather than a medulloblastoma or, if it is an example of the latter, is quite an unusual one. Figure 12 does not show a good impregnation of the oligodendroglia; figure 34 is not clear; figure 70 is not good; figure 108 does not illustrate Schilder's disease as well as a good Weigert-Pal stain of the cerebral cortex and white matter would have done, and figure 220 is at too low a magnification. The statement on page 26 that massive cerebral hemorrhage is always associated with arterial hypertension is not correct and not in accord with the discussion on the following pages of the intracerebral hemorrhage which is often associated with aneurysms.

There is a list of a few well selected references and an adequate index.

**A Textbook of Gynæcological Surgery.** By Victor Bonney, M.S., M.D., B.Sc., *Consulting Gynæcological and Obstetric Surgeon to the Middlesex* Hospital, London. Fifth edition. Cloth. Price, $15. Pp. 928, with 590 original drawings by the author and 17 color plates. Paul B. Hoeber, Inc., 49 E. 33rd St., New York 16, 1948.

This is a good book on gynecologic surgery written by master surgeons who set forth concisely their opinions on subjects pertaining to gynecologic surgery. The illustrations are mostly simple pen and ink drawings which lend themselves well to elucidating the steps of the various operations. The simplicity of the technic emphasizes the points that they are trying to bring out. Anatomically they are not correct in many respects, which is to be expected, since the artistic ability of great surgeons must necessarily be limited.

One can disagree with their choice of operations in some instances, such as the Baldwin operation for artificial vagina, which has largely been given up as a standard procedure in this country. One could also question the abdominal approach for splitting the cervix to relieve dysmenorrhea. This can be much more simply done from below, and perhaps the results obtained would not justify the procedure.

In discussing removal of uterine polyps the important point of curetting the base of attachment of the polyp was ignored and not mentioned even in the after-treatment in such cases. They make a much bigger job of morcellation of a submucous fibroid than necessary. Wedge excisions repeated after putting the cut surfaces together with tenacula and repeating the excision are all that is necessary.

The discussion of vaginal hysterectomy is not convincing. It is much easier to open the cul-de-sac of Douglas posteriorly to the cervix primarily and to detach the uterosacral ligaments, allowing the cervix to descend before exposing and opening the uterovesical pouch. This having been opened with a scissors there is no need for the step of tearing it open further with the fingers as shown in figure 148. Figure 149 shows the fornix being incised, not the cervix, as stated in the inscription. The uterovesical fold should be opened in the midline and not as shown in figure 150.

Figure 153 shows the lower portion of the broad ligament being palpated. There is nothing of importance to palpate except the uterine artery the location of which should be known and which should be exposed by dissection before clamping and tying. There is no reason for tying the broad ligament as shown in figure 157. One tie for tube, round ligament and anastomosing branch of the ovarian artery, one on the uterine artery and one on the cervical branch of the uterine artery are all that are useful.

The description of the LeFort's operation is not as clear as one would desire.

The discussion of cesarean section operation is obviously from the point of view of a surgeon and not of an obstetrician. Indications such as elderly primipara, ovarian cysts, and fibroids threatening to obstruct the birth canal are not considered indications for cesarean section unless there are other factors such as incarceration of the cyst or fibroid or elderly primiparas who have had a trial of labor and failed or who have hypertension or some other medical complication. The authors advocate cesarean section in all cases of decompensated heart. In many of these cases the decompensation can be corrected by proper medical management and the delivery can then be from below.

Cesarean section for locked twins or for breech with extended legs is not justified. Most oblique and brow presentations will deliver spontaneously.

One should not administer ergot before opening the abdomen in cesarean section. In a patient unusually sensitive to this drug, tetanic traction which could be dangerous to the fetus may occur.

There is no evidence to support the view that low cervical cesarean section is more difficult than the classic type when performed by competent surgeons thoroughly familiar with both technics.

The discussions of total, subtotal and Wertheim's hysterectomies are very good. More emphasis is placed on myomectomy than is usually given in American textbooks; this is a form of conservatism to be commended in many cases. However, the coincidence of cancer and fibroids must be kept in mind and this conservatism should not be carried too far when extensive myomatous degeneration is present.

Urinary incontinence operations are well handled, as are ovarian tumors and ovarian cysts.

The addition of the chapters on operations on the intestinal tract, including abdominovaginal excision of the rectum are valuable, although not ordinarily included in textbooks on gynecology. The authors' discussion of preoperative and postoperative management is very good.

In general, this is to be considered an excellent work for men doing gynecologic surgery. Its lack of consideration of medical-gynecologic problems would make it undesirable as a textbook for undergraduate teaching in gynecology.

**Juvenile Rheumatism: A Clinical Survey.** By G. E. M. Scott, M.B., L.R.C.P., L.R.F.P.S., Honorary Medical Clinical Assistant, Royal Melbourne Hospital, Melbourne, Australia. Cloth. Price, 25s. Pp. 163. W. Ramsay (Surgical) Pty., Ltd., 340 Swanston St., Melbourne, C. 1, 1948.

The object of this monograph, as stated in the preface, is to present a condensed review of the author's experience in juvenile rheumatism. Dr. Scott has given much thought and trouble to make this monograph a survey of the most important and recent clinical and laboratory investigations, rather than a medium to express his own personal opinions. Although the author's views are evident to the reader they are not emphasized, and there are few critical remarks.

This book deals entirely with problems of rheumatic fever; juvenile rheumatoid arthritis and other less common forms of childhood rheumatic disease receive no attention. The opening and closing chapters are devoted to the social aspects of rheumatic fever: the comparative incidence in Australia, England and the United States, the mortality rate and the social care of children with rheumatic fever, rheumatic heart disease and chorea. The other chapters deal with the modern trend of thought regarding the etiology, pathology and epidemiology, outline the recent investigational studies and offer an excellent bibliography.

Pictorial illustrations are absent from this monograph, but there are many illustrative case protocols. The cardiologists, pediatricians and obstetricians are given a good many examples of insidious and unusual cases in which the diagnosis is seldom made or suggested when the heart is already damaged. The symptom complex is not sufficiently described to serve the purposes of the undergraduate student and the general practitioner; the chapters dealing with therapy and prophylaxis serve them better.

This monograph will aid those who seek to be up to date particularly in regard to the considerations of etiology, pathogenesis and prophylaxis of rheumatic fever.

**The Uses of Penicillin and Streptomycin.** By Chester Scott Keefer, M.D., Wade Professor of Medicine, Boston University School of Medicine, Boston, Mass. Porter Lectures, Seriec 15. Cloth. Price, $2. Pp. 72. University of Kansas Press, Journalism Building, Lawrence, Kan., 1949.

This small volume contains the text of the three Porter Lectures delivered by Dr. Keefer under the auspices of the University of Kansas School of Medicine. The first lecture presents a detailed discussion of the practical aspects of the use of penicillin and its various dosage forms in clinical practice. The second lecture presents a similar discussion for streptomycin. The third, and much shorter lecture, is historical and traces the development of the concept of antibiosis from the observations of Wollstein in 1876 on anthrax to the discovery of streptomycin. These lectures present a readable and useful summary of the practical and rational use of penicillin and streptomycin in everyday clinical practice.

**Diseases of the Skin.** By Oliver S. Ormsby, M.D., Attending Dermatologist to the Presbyterian Hospital of Chicago, Chicago, and Hamilton Montgomery, M.D., M.S., Associate Professor of Dermatology and Syphilology, Mayo Foundation for Medical Education and Research, Graduate School, University of Minnesota, Rochester, Minnesota. Seventh edition. Fabrikoid. Price, $18. Pp. 1462, with 782 illustrations. Lea & Febiger, 600 S. Washington Square, Philadelphia 6, 1948.

The new revision of this standard work has eliminated obsolete material and permitted the addition of new information on tropical diseases and the treatment of syphilis and the application of antibiotics in dermatologic therapy. An attempt has been made to utilize the standard nomenclature of diseases but not completely. The history of this textbook of diseases of the skin is a record of continuing leadership from the first Montgomery and Hyde edition to the present volume, which carries again the Montgomery name.

**Handbook of Diseases of the Skin.** By Richard L. Sutton, M.D., and Richard L. Sutton, Jr., M.D., Associate Professor of Dermatology and Syphilology, University of Kansas Medical School, Kansas City. Cloth. Price, $12.50. Pp. 749, with 1057 illustrations. C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3, 1949.

Here is a new textbook, rather than a revision. The book is based on what the authors have learned by a critical analysis of their own extensive experience in writing and their equally extensive clinical experience, both of which furnish a solid basis for a well balanced and practical treatise.

This edition is characterized by the concise and forceful manner of the junior author. Everything in dermatology is covered, and extensive use is made of small type for less common or less important conditions and for elaborations on or digressions from the main subject matter of individual chapters. The diseases are grouped for discussion on a basis of etiology as far as that is possible, and a special effort appears to have been made throughout the text to attain conciseness and yet thoroughness. The junior author presents tersely his own interpretations of disease processes and his own preferences for treatment, with which not all dermatologists agree, but he resorts freely to current dermatologic and nondermatologic literature. Numerous references are embodied in the text directly in conjunction with the statements made, so that the reader may readily amplify the information furnished by reference to original articles.

This may make the text less easy for the student to read but increases its interest and value for the general practitioner and particularly for the dermatologist. It is recommended to all three. The 719 pages of text contain over a thousand small but excellently reproduced clinical photographs and microphotographs that add materially to the descriptive text. The paper, printing and binding are good and the small as well as the large type is easy to read.

This handbook is endorsed without reservations.

**Die Tuberkulosebekämpfung Grundlagen und Wege zu einer einheitlichen und erfolgreichen Durchführung.** Von Obermedizinalrat Dr. Rolf Griesbach. Second edition. Boards. Price, 27 marks. Pp. 460, with 38 illustrations. Georg Thieme, Diemershaldenstrasse 47, Stuttgart O, 1948.

This book of 460 pages contains a large store of information concerning the tuberculosis control program in Germany. The graphs of mortality rates are especially enlightening. In 1890 the rates were 24 per 10,000 population. There was a gradual and almost constant decrease until 1914, when the rate was only about 12 per 10,000. By 1921 the rate was again down to 12, and it decreased regularly to 7 per 10,000 in 1934. Thus, except for the period during and shortly after World War I, there was a definite and constant decrease in mortality between 1890 and 1934. The effects of war did not continue as long as might have been expected. Special graphs on mortality by sexes show a higher rate among men at all periods of life except from 5 to 30 years. The highest mortality rate was reached (1934) by men between the ages of 60 and 70 years. This was over 12 per 10,000; while among women of the same age it was slightly more than 8 per 10,000. The various fundamental procedures employed in the control of tuberculosis are described in considerable detail, including the diagnostic armamentarium, with special emphasis on roentgen ray, inspection of the chest, and hospital and sanatorium facilities. All forms of tuberculosis are discussed, together with therapeutic procedures and methods of prevention.

A high mortality was reached again during World War II. However, with fundamental work in progress there is good reason to expect that tuberculosis will soon reach its prewar level and continue to decrease as it did after World War I.

**Vitamin A Requirement of Human Adults: An Experimental Study of Vitamin A Deprivation in Man. A Report of the Vitamin A Sub-Committee of the Accessory Food Factors Committee.** Compiled by E. M. Hume and H. A. Krebs. Medical Research Council Special Report Series No. 264. Paper. Price, 3s. Pp. 145, with 17 illustrations. His Majesty's Stationery Office, York House, Kingsway, London, W.C. 2, 1949.

Prompted by the critical food needs and the accompanying problems of rationing during the war, the British Medical Research Council in 1942 undertook to determine the vitamin A and carotene requirements of human adults.

Twenty-three healthy young adults (20 men and 3 women) between the ages of 19 and 34 years received a diet deficient in vitamin A (containing less than 70 international units of beta carotene daily) for six and one-half to twenty-five months. Sixteen subjects received the diet unsupplemented until they showed unmistakable signs of deficiency or left the experiment for reasons unrelated to the study. They were then given graded doses of vitamin A or carotene. Seven subjects served as positive controls, 2 of them receiving 2,500 international units of vitamin A daily as a natural concentrate and 5 receiving about 5,000 international units daily of carotene as beta carotene in oil or margarine or as carrots, spinach or cabbage.

The length of time required for signs of deficiency to appear was much longer and the number of subjects showing marked deficiency was much smaller than expected; no changes occurred until after eight months on the deficient diet, and 1 subject showed no signs of depletion even after twenty-four and one-half months on the deficient diet. A variety of tests, including clinical examination, skin biopsies, slit lamp examination of eyes and psychologic tests, were made regularly, but the only ones which gave positive results and proved useful as criteria of deficiency were the plasma level of vitamin A and the capacity for dark adaptation. A direct correlation between these two measurements was observed. Subjects with pronounced deterioration of dark adaptation had plasma vitamin A values below 40 international units per hundred cubic centimeters, whereas deprived subjects whose dark adaptation remained normal had plasma levels of vitamin A above 40 international units per hundred cubic centimeters.

On the basis of studies of graded doses of vitamin A in the 3 subjects who were adequately depleted, the minimum protective dose was found to be 1,300 international units daily, with 2,500 international units daily recommended as the amount required to cover individual variations.

The requirement of carotene is based on "maximum effective dose" (intake minus fecal excretion) rather than on intake and varies with the source of carotene. The minimum protective dose was 1,500 international units daily, with 3,000 international units daily necessary to cover individual variations, assuming carotene is 100 per cent available. The single value suggested for daily intake of carotene from natural foods is 7,500 international units, or three times the daily requirement for vitamin A.

The study was comprehensive and well planned. Many of the determinations were carried out by several different laboratories. Valuable details of chemical methods and comparisons of methods for measuring dark adaptation are included. The report is a valuable addition to the literature on vitamin A requirement and on the role of vitamin A in human metabolic and nutritional economy.

**Histopathology of Irradiation from External and Internal Sources.** Edited by William Bloom, M.D., Professor of Anatomy, Department of Anatomy and Institute of Radiobiology and Biophysics, University of Chicago, Chicago. National Nuclear Energy Series, Manhattan Project Technical Section, Division IV, Plutonium Project Record, Volume 22 I. Cloth. Price, $8. Pp. 808, with illustrations. McGraw-Hill Book Company, Inc., 330 W. 42d St., New York 18, 1948.

This volume deals with the histologic effects of various types of irradiation on several different animal species. The lesions of total body irradiation, obtained from externally applied roentgen, gamma and beta rays, also fast and slow neutrons, are compared with those produced by a variety of alpha, beta and gamma ray emitters given internally.

Each major organ or tissue forms the subject of a separate chapter. There are a large number of contributors and each concentrated on a particular organ. The plan of the book is to give in detail the effects on a given organ of one type of total body irradiation from an external or internal source and with this as a base line to compare the changes produced by external and internal radiations from other sources.

The authors have assembled a large mass of material on the histologic lesions of irradiation. The data is presented well and is illustrated by many good photomicrographs.

Items of merit include use of a variety of animals, numerous radioactive elements and varied, accurately measured dosages. There are several limitations of omission. In places the data, especially those pertaining to recovery, are too brief or incomplete. Long term effects of radiation are omitted. References to the literature are relatively scant. As the authors state, the work throws no light on such important problems as cause of radiation death and variation in tissue susceptibility to radiation.

Nevertheless, the book is a commendable effort. It should prove a valuable reference source, particularly to pathologists and histologists.

**Anson Jones: The Last President of Texas.** By Herbert Gambrell. Cloth. Price, $5. Pp. 462, with one portrait. Doubleday & Co., Inc., 14 W. 49th St., New York 20, 1948.

History is replete with the names of physicians who led double lives in the sense that the practice of medicine was only one of two major interests, the other being art, literature, politics, statesmanship, exploration or similar activities. Dr. Anson Jones was the last president of Texas before it joined the United States. He was an amazing, dramatic and romantic figure, a leader with all of the attributes that leaders require. He could talk, he could write and he had courage. Occasionally he may have been misguided, but his motivations were sincere. Professor Gambrell has humor, and his portrayal of Anson Jones is highlighted by the warmth of his interest in his hero.

# Queries and Minor Notes

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

## EATING HABITS OF CHILDREN

**To the Editor:—A 6 month old female baby refuses milk and, in fact, refuses to eat anything—so the mother says! Yet, this child weighs 16 pounds (7,257 Gm.) and weighed 5½ pounds (2,495 Gm.) at birth—one month prematurely. The child received plasma for diarrhea as a newborn infant. The liver is not abnormally enlarged nor is there icterus (no evidence of homologous serum hepatitis) or anemia. The mother is definitely an anxious and emotional person. What practical measures can I now take?**

**M.D., Massachusetts.**

Answer.—This premature infant weighed 5½ pounds at birth and weighs 16 pounds at 6 months of age. The average 6 month female infant, 26 inches (66 cm.) in length, will weigh 15.5 pounds (7,031 Gm.).

The mother of this baby claims that her daughter refuses milk and refuses to eat. However, the mother is described as being anxious and emotional. The fact that the infant's weight is adequate would belie the mother's claim that the infant neither eats nor drinks its milk.

The increment of growth in the first few months of life is much steeper than in the latter part of the first year, and most infants eat avidly in the first few months. As the rate of growth slows, the appetite gradually drops off and the anxious or emotional type of mother is likely to force her infant beyond its appetite and actual food requirements. The mother at once is convinced that her infant not only is refusing all milk but all food offered. Hence many mothers honestly make this claim and feel that their baby is starving; it is usually most difficult to convince them that the baby is of average, or above average, nutrition.

The first practical measure is to convince the mother that the infant is in good nutrition. Second, convince her that the amount of food the infant needs will depend on how fast the baby has grown. Third, convince such a mother that the amount of food the baby actually wants will probably be the amount that the infant needs, rather than the amount which she has decided the baby should have.

The following items from "Children Like To Eat," published by the Children's Bureau, Washington, D. C., are practical points which will aid an emotional mother in feeding her baby: 1. Children will eat if you "let" them. 2. Do not force food. 3. Let the child's needs determine how much he wants. 4. Help him to help himself. 5. Watch when he is ready to take the next step. 6. Have pleasant surroundings. 7. Be casual, friendly, patient. 8. Don't scold, nag, fuss: 9. Respect your child's likes and dislikes.

## EXPOSURE TO CUTTING OILS

**To the Editor:—Please furnish information concerning prolonged contact and inhalation of "solvent oil," which, as I understand it, is a commercial "emulsion" oil of petroleum derivative used in connection with grinding wheels for cooling the metal and carrying away results of grinding. What are the outstanding possibilities from prolonged use? Are there other injurious materials used in making these products?**

**R. A. Blossom, M.D., Long Beach, Calif.**

Answer.—Scores of different oily cutting compounds are regarded as "solvent oils." Usually the quantity of oil entering the emulsion is so low as to be negligible except as a source of skin diseases. Cutting oils are common causes of dermatitis, while the more concentrated heavy oils may induce "oil furunculosis." Lighter fractions of petroleum oils (e. g., naphtha, kerosene and mineral spirits) are ready causes of dermatitis. Many cutting oils of the water-soluble type are further treated with sulfur or chlorine. As a result, respiratory irritation may arise. In some European countries, the quality of oil available long has been associated with cancerogenic properties, leading notably to skin cancer. Pulmonary carcinoma from the inhalation of oil mists has been suspected but possibly never demonstrated. In the United States oil cancers of any type are little known to industry. Inhalation of high concentrations of the vapors of such petroleum fractions as gasoline or naphtha may promptly be followed by an acute intoxication, "naphtha jags," closely resembling acute alcoholism. Prolonged exposure occasionally leads to chronic naphtha poisoning, a state resembling multiple sclerosis.

## HYALURONIDASE IN RHEUMATIC FEVER

**To the Editor:—Please give a brief account of the significance of hyaluronic acid and hyaluronidase in rheumatic fever.**

**E. T. Drake, M.D., Williamson, W. Va.**

[This inquiry was referred to two authorities, whose respective replies follow.—*Editor.*]

Answer.—Hyaluronic acid occurs in the interstitial spaces in animal tissues. It is a mucopolysaccharide acid and seems to hold water, holds the cells together in a jelly-like matrix and serves as a lubricant and shock absorber. Hyaluronidase is an enzyme which depolymerizes and disaggregates hyaluronic acid.

Hyaluronic acid may occur in groups A and C hemolytic streptococci; hyaluronidase also occurs in strains of hemolytic streptococci of groups A and C. The concentrations of these substances, however, do not appear to bear relationship with the ability to produce rheumatic fever by certain strains of the streptococci.

Studies in the viscera and in striated muscle fascia and tendons reveal that hyaluronate and chondroitin sulfate are present in concentrations roughly equal. It has been demonstrated that hyaluronic acid in common with other asymmetric molecules may increase the sedimentation rate in vitro, or after intravenous injections. Purified testicular hyaluronidase decreases in vitro the sedimentation rate of patients, especially in rheumatic fever.

Hyaluronidase increases the spreading of india ink injected into rabbits. In human subjects, with active or inactive rheumatic fever, injection of the enzyme with the dye T-1824 is said to cause unusual reactions with large diffusion of the dye and local edema. Salicylates inhibited the spreading reaction in these cases. The explanation of this effect, as well as the beneficial action of salicylate on some rheumatic manifestations, may be found in an inhibition of hyaluronic production of mesenchymal cells.

The practical importance of hyaluronic acid and hyaluronidase in rheumatic fever must be left to the accumulation of further experimental studies. It is conceivable that the precipitating agent, the rheumatic fever-producing strains of beta hemolytic streptococci, may invade tissues with the aid of their own production of hyaluronidase and hyaluronic acid.

Answer.—Hyaluronic acid is a mucopolysaccharide substance found in all mesenchymal tissue (present in the interstitial substance of connective tissue). In mammals, the highest concentrations are found in synovial fluid and skin, and the next highest in the vitreous humor. The exact source of hyaluronic acid remains unknown, but it has been suggested that young fibroblasts in undifferentiated connective tissue may produce it in large quantity. Hyaluronic acid is thought to be influential in the protection offered by the skin against bacterial invasion. The only micro-organisms known to produce hyaluronic acid are groups A and C of hemolytic types of streptococci (in the mucoid phase).

Hyaluronidase is an enzyme which acts (hydrolysis) specifically on hyaluronic acid. The enzyme is rather ubiquitous, being encountered wherever there is destruction of normal tissue and being present in many pathogenic bacteria, snake venoms and spermatozoa. Hyaluronidase has the ability to initiate and spread infections, although this is a feature of other enzymes as well. When injected into connective tissue, hyaluronidase increases capillary permeability, whereas the intravenous injection of hyaluronidase has no such effect.

A possible relationship between hyaluronic acid, hyaluronidase and rheumatic diseases is suggested by: (1) the proposal of Klinge that rheumatic diseases are primarily diseases of the cement substance; (2) the fact that sulfonamide compounds, admittedly inactive in rheumatic diseases, have no influence on hyaluronidase (Guerra); (3) the relatively low quantities (one sixth to half of normal) of plasma enzymes with anti-invasive reactivity in patients with rheumatic fever as compared with healthy persons (Haas), and (4) the inhibitory action of small amounts of sodium salicylate on the spreading of india ink or dye injected together with hyaluronidase (Guerra and others).

Guerra is of the opinion that rapid extension of the involvement of mesenchymal tissue in rheumatic fever suggests a partial removal of the protective barrier (hyaluronic acid?) offered by the tissue ground substance. Hyaluronidase is one of the substances capable of overcoming this barrier, although other enzyme systems may also be involved.

Lack of specificity of the relationship between hyaluronidase and rheumatic diseases is suggested by evidence that: (1) the inactivation of hyaluronidase by human serum is a complex reaction, the details of which are not yet completely understood; (2) the presence of inorganic ions such as chloride and phosphate may be as important as the relative concentrations of hyaluronidase and serum in patients with rheumatic disease (Meyer and Ragan); (3) changes in chondroitin sulfates and their protein complexes may be of greater importance for the rheumatic processes than the changes associated with hyaluronic acid (Meyer and Ragan), and (4) oral administration of salicylates affects the hyaluronic acid in synovial fluid, but it is unlikely that inhibition of hyaluronidase is the only (or even the most significant) modus operandi for the known antirheumatic effects of salicylates.

The evidence of a relationship between inactivation of hyaluronidase by human serum and the rheumatic diseases furnishes an interesting theory to explain the action of salicylates in rheumatic fever. However, at the present time the evidence must be considered more tentative than conclusive.

## INTRAVENOUS ADMINISTRATION OF CHOLINE CHLORIDE

*To the Editor:*—In severe liver damage methionine has been used intravenously in dose of 5 to 10 Gm. in 3 per cent solution in 5 per cent dextrose. I believe that choline chloride has also been so used, as, for example, in carbon tetrachloride poisoning. What are the intravenous dose and method of administration of the latter? M.D., Pennsylvania.

Answer.—Choline chloride has been administered intravenously to laboratory animals and to man. Cats tolerate 15 mg. per kilogram of body weight without toxic effects, while 30 mg. per kilogram produces a reversible arrest of respiration. The material is rapidly destroyed in the body, presumably by cholinesterase in the liver. For this reason little appears in the urine after intravenous injection; 0.8 to 0.9 mg. per kilogram per minute in 0.2 or 0.4 per cent solution, in fact, may be injected practically indefinitely.

A survey of recent literature revealed no record of the intravenous use of choline in cases of hepatic injury; most investigators are content to give the material by the oral route. There is some evidence to show that it exerts its lipotropic effect on the fatty liver of human beings when given in this way (Beams, A. J.: J. A. M. A. **130**:190 [Jan. 26] 1946). However, proof of its activity in human beings is not conclusive. The same statement also may be made with regard to methionine, as the recent report of the Council on Pharmacy states (J. A. M. A. **133**:107 [Jan. 11] 1947).

In view of the fact that most studies on the effects of parenteral choline therapy are by no means recent, and since the indications for its use for human beings are not clearly defined, it does not seem advisable to employ it by the intravenous route in patients with hepatic injury or disease.

## ALLERGIC REACTION TO IMMUNIZATION

*To the Editor:*—I gave 1 cc. of diphtheria-pertussis-tetanus antigen combined to a boy 6 months old. After a few seconds the baby stopped breathing, his eyes closed, his body relaxed—apparently he was dead. External stimulation and a finger in his throat made the baby breath again.. There was no need of injecting epinephrine hydrochloride. The baby is normal and weighs 20 pounds (9,072 Gm.). Was this an allergic phenomenon? Should I give him the second and third injection? What precautions should I take? Frank Grimaldi, M.D., Brooklyn.

Answer.—The occurrence that you describe appears to have been an allergic reaction. However, if the antigen was injected intramuscularly, it is possible that some of the material entered a small blood vessel. For a while one of the biologic houses did not place a triple antigen on the market because of the difficulty in refining pertussis vaccine. At present, there is a triple antigen available which is administered in three doses of 0.5 cc. each, and it is claimed that unpleasant reactions are almost unknown. It might be well to perform a Maloney test for toxoid sensitivity. If the result is positive and further injections are to be given, it would be advisable to use a highly refined product (regular dose 0.5 cc.) and administer the second regular dose in divided quantities of 0.1, 0.2, and 0.2 cc. about five days apart. If there are no unpleasant reactions, the regular third dose of 0.5 cc. could be given in one injection about six weeks later. Should it be decided to continue the immunizations, it would be best to have the baby in a hospital when the procedures are performed.

## TREATMENT OF GASTRIC CRISIS

*To the Editor:*—Gastric crises of tabes dorsalis developed in a 58 year old man twelve years ago. He received treatment with tryparsamide and bismuth compound for three to four years without effect on attacks of vomiting. He then had six treatments with fever which stopped the gastric crises for five years. Vomiting attacks then recurred, and he has had three of them in the past fifteen months which incapacitated him for work for three to four weeks at a time. He presents the following positive physical findings: perforated nasal septum, Argyll-Robertson pupils, partial deafness, absent knee jerks and positive Wassermann and Kahn reactions (4 units). The spinal fluid shows: globulin normal, colloidal gold curve normal and Kahn reaction negative. What can be done to prevent recurrences of the gastric crises? Would penicillin be of value? If so, what is the recommended dose? M.D., Ohio.

Answer.—It is assumed that intrinsic gastrointestinal disorders have been excluded as possible causes for the vomiting attacks. Once true gastric crisis in the syphilitic has occurred, there is not at present any specific treatment that will insure prevention of recurrence. During attacks, the liberal use of atropine, sedatives and maintenance of water and electrolyte balance may shorten and reduce the severity of the episode. Morphine is to be avoided, particularly when attacks are frequent, because of the danger of addiction. Between attacks, vitamin B, in doses of 100 to 200 mg. daily, adequate diet and mild sedation are recommended. Autohemic injections at intervals of one to two weeks have been used with questionable success. Total body ultraviolet radiation, suberythemal doses at one to two week intervals, may be of some value. The possibility of the psychotherapeutic role of these treatments is obvious. Since emotional factors may play a part in the precipitation of crises, psychotherapy should not be overlooked.

If pain is severe and all other measures have failed, chordotomy may be tried. Interruption of the spinothalamic tract fibers at about the third dorsal segment has proved successful in relieving the pain of gastric crises in the majority of patients so treated. The vomiting attacks, being chiefly vagal in origin, cannot be expected to be affected by chordotomy. Section of the vagus nerves to the stomach has met with some success in the control of vomiting. From the experiences gained from the extensive employment of vagotomy in the treatment of peptic ulcer, one can reasonably expect a reduction of motility and tonicity of the stomach after complete vagus section.

If heavy metal therapy has not been adequate, penicillin may be given for that reason alone. Penicillin, however, has not been shown to prevent the recurrence of gastric crises, regardless of the status of antisyphilitic therapy.

## HISTAMINE REACTION

*To the Editor:*—A man, aged 30, began having spontaneous flushing of the skin four years ago. These attacks come on without warning, but are usually initiated by stress or strain as in a golf game, or in hot weather when he becomes overheated, or on physical exertion, such as lifting. His first sensation is tingling and burning around his face, then on the inner surface of the arms and in the axillas. The flushing of the skin and itching then spreads over his entire body. At the height of the attack his face is fiery red and has a mottled, splotchy appearance. This phenomenon usually clears up in thirty minutes; it occasionally lasts as long as an hour. He may have two attacks in the same game of golf. He averages two or three attacks a day. Antihistaminic drugs and other types of treatment have not helped. Please suggest diagnosis and treatment. M.D., North Carolina.

Answer.—The condition described most closely resembles the vasodilatation produced by excessive histamine release. While the stimulus in other cases may be allergy, cold or heat or may be emotional or perhaps of another type, the particular stimulus appears to be heat engendered internally. If there is a fall in blood pressure on these occasions it would be additional evidence of extensive histamine release. Antihistaminic drugs would be expected to be helpful. However, in this case the amount of histamine released may be too great to be combated by the average dose of antihistaminic drug. It is suggested that larger doses (such as a 100 to 150 mg. of tripelennamine hydrochloride) be tried. The medication should be given about one hour prior to the anticipated attack. A tolerance to heat may possibly be attained by systematic exposure to heat stimuli. One method would be to place the arms in hot water for about five minutes twice daily, to be followed each time by an immersion in cold water. In some cases injections of histamine have produced results. One procedure is to give 0.5 to 1 mg. of histamine in 500 cc. isotonic sodium chloride solution intravenously, taking two hours to complete the injection. Several such daily injections may create a more stabilized state. Another method is to give subcutaneous injections of histamine, preferably twice daily, over a period of several weeks, beginning with doses of about 0.10 cc. of 1:100,000 strength and gradually increasing until 0.20 or 0.30 cc. of 1:1,000 is reached.

## TREATMENT OF AMENORRHEA

*To the Editor:*—A high school girl aged 17 started menstruation at age 13. She had some pain but was regular. She went on a trip in 1947 and has not menstruated since. Her health is good. Indefinite abdominal pain which she complained of in childhood has completely stopped. A gynecologist reports no abnormality in uterus or ovaries. Basal metabolism tests on three occasions showed minus 31, minus 11 and minus 20 per cent. Physical examination did not elicit any abnormality. Treatment with thyroid extract for nine months, 2 to 3 grains (0.12 to 0.2 Gm.) daily with occasional interruptions and injection of estrogen and progesterone combined monthly (four months) thus far has produced no results (Zonder's method). Please suggest treatment and prognosis. M.D., New York.

ANSWER.—Amenorrhea is only a symptom; hence a cause must be sought. In some cases this is simple, but in many instances it is difficult or impossible. In the latter cases, treatment is usually unsatisfactory. Fortunately menstruation is restored spontaneously in some cases, with or without treatment.

In most instances of amenorrhea hormone therapy is used, but, whereas it is fairly easy to induce bleeding, this does not necessarily mean that the patient is having normal menstruation. In all cases a complete physical examination must be made to rule out not only pelvic but also general disturbances. Also the patient's nutrition should be investigated. In this case further studies should be made of thyroid function because of the three low basal metabolic rates. Thyroid therapy should be continued as long as it is necessary.

Bleeding may be induced by means of estrogens alone, estrogens plus progesterone, gonadotropins and radiation therapy. If estrogens alone are used 1 mg. of diethylstilbestrol should be prescribed every night for twenty-one nights, or 50,000 I. U. of estradiol dipropionate or benzoate given intramuscularly three times a week may induce bleeding. However, to produce cyclic bleeding this therapy must nearly always be repeated. The simplest way to use the combined estrogen-progesterone treatment is that recommended by Zondek, which consists of the administration of 25 mg. of progesterone plus 5 mg. estradiol benzoate during two days. This therapy also must usually be repeated to produce cyclic bleeding. If gonadotropins are used one may employ chorionic gonadotropins or equine gonadotropins or both. The results of gonadotropin therapy thus far are not satisfactory even when large doses are used. When this form of therapy is carried out the patient should receive five injections of 2,000 to 3,000 I. U. of equine gonadotropin at three day intervals followed by five injections of 6,000 I. U. of human chorionic gonadotropin at three day intervals. When all hormone therapy fails the last resort is radiation treatment, either to the pituitary or to the ovaries or to both. The results of this treatment are good, but there is considerable controversy considering the possible harm which may result from this type of treatment, the harm being to the third and fourth generation of offspring. This treatment should only be a last resort and should be carried out by an experienced roentgenologist who will use the proper technic and doses.

## CONVALESCENCE IN RHEUMATIC FEVER

*To the Editor:*—A boy, 7 years of age, became ill with rheumatic fever on Dec. 1, 1948. Onset was sudden and not preceded by an infection or other illness. His complaints were pain in wrist, shoulder and knee joints, migratory in type; fever, and transient macules of skin. The sedimentation rate (Wintrobe) was rapid, 93 mm. at sixty minutes. There were 27,000 leukocytes. For one day rheumatic peritonitis occurred. Heart rate was 120, with regular rhythm and without heart murmur. Temperature was 101 F. Five grains (0.3 Gm.) acetylsalicylic acid was given every two hours; multicebrin® (a multivitamin preparation) and 100 mg. ascorbic acid were given daily. A heart murmur, apex systolic, appeared within a few days and persists. Polyarthritis comes and goes. At the end of January the boy's temperature remained at 98 to 99 F., joint pain was gone and he felt "good"; Wintrobe sedimentation rate showed 14 mm. at fifteen minutes, 85 mm. at forty-five and 106 at one hour. Salicylates have been taken every two hours since onset of illness. An extrasystole every fifth beat with a dropped pulse beat occurs. On January 19, 1949, his temperature was 98 F.., joint pain was absent and he was still on the medication described. Sedimentation rate at this time is rapid—82 at sixty minutes. Please suggest treatment. When may the child be allowed out of bed? Loren G. Burt, M.D., Alma, Mich.

ANSWER.—The clinical course is characteristic of rheumatic fever. The acute phase has passed, but active disease persists, as indicated by the abnormal sedimentation rate. Factors other than the sedimentation rate are useful in appraising continued rheumatic activity during the convalescent period. It is reassuring to have freedom from symptoms and a normal temperature after cessation of salicylate therapy. It is now safe and essential to omit the acetylsalicylic acid unless there is a return of joint symptoms. An improvement in appetite and a steady gain in weight would be reassuring. A normal conduction time (P-R interval) in the electrocardiogram would also be helpful information.

In summary, when the child is off salicylates, is afebrile, symptom free and gaining weight, and when the white blood cell count and the sedimentation rate have returned to normal, it is safe to allow slowly increasing activities over the ensuing months.

## CHRONIC INFECTIOUS MONONUCLEOSIS

*To the Editor:*—In The Journal, January 22, page 258, an article on chronic infectious mononucleosis by R. Isaacs is abstracted from the journal *Blood*. This article discusses use of adrenal cortical extract in the treatment of this condition. I have a 4 year old white female patient in whom the symptoms leukocytosis and relative monocytosis have persisted since the acute stage of the disease last August and would appreciate an opinion on the efficacy of this treatment. My patient does not have leukemia, at least at present. Her 6 year old sister had acute infectious mononucleosis fourteen days after this patient, and has completely recovered. Kenneth D. Rose, M.D., Lincoln, Neb.

ANSWER.—Scientific evidence is not available that adrenal cortical extract has any specific effect on the wide range of symptoms and pathologic lesions in infectious mononucleosis. Virtually all of the clinical symptoms in infectious mononucleosis have been explained on the basis of perivascular aggregates of normal and abnormal lymphocytes that may involve most of the organs and tissues of the body with the exception of the bone marrow. The occurrence of lymphocytes in the adrenal glands is difficult to evaluate in relation to this disease since this finding is so common in the average series of autopsies. Absolute lymphocytosis may persist for several months after infectious mononucleosis, but if it persists for six months as in the 4 year old child, the diagnosis must be considered in doubt unless it has been fully established by the finding of the characteristic atypical lymphocytes in the blood and by a positive reaction to a heterophil antibody test. The presence of leukocytosis and monocytosis in this child is not clear, since, characteristically, absolute lymphocytosis is found in infectious mononucleosis. Further clinical and laboratory data are necessary in this child to make sure that the disease is not a leukemic process or an infectious disease other than infectious mononucleosis. Sternal aspiration would be indicated in this case. For infectious mononucleosis there is no specific therapy; treatment is symptomatic as in other acute infections.

## OPTIC NEURITIS IN MULTIPLE SCLEROSIS

*To the Editor:*—Is optic neuritis an early and important diagnostic manifestation of multiple sclerosis? Recently, in a young woman, optic neuritis developed on one side followed not long after by involvement on the other. Her abdominal reflexes are suggestive of beginning multiple sclerosis. Other signs are absent at this time. M.D., Illinois.

ANSWER.—Optic neuritis is frequently an early and important sign of multiple sclerosis. The primary lesion is a retrobulbar neuritis, with a selective involvement of the papillomacular bundle at any level in the optic pathway. If the focus in the nerve is close to the nerve head, associated edema and other signs of optic neuritis by ophthalmoscopic examination are to be expected. Lesions distant from the disk may not cause intraocular changes in the acute stage. Rarely the retinal changes are so marked, with papilledema, hyperemia of the disk, overfilling of veins, blurred margins, an obscured physiologic cup, hemorrhages and exudates, and star-shaped figures at the macula, as to be confusing with the papilledema due to increased intracranial pressure. A central scotoma in the visual field, however, is essential to the diagnosis. Loss of vision varies within wide limits.

Without other signs of multiple sclerosis, optic neuritis is only a presumptive diagnostic sign of the disease. Watkins (Watkins, A. L.: The Cerebrospinal Fluid in Optic Neuritis, "Toxic Amblyopia" and Tumors Producing Central Scotomas, *New England J. Med.* 220:227-231 [Feb. 9] 1939) found many causes, other than multiple sclerosis, for retrobulbar neuritis, but when changes were found at the same time in the colloidal gold reaction of the cerebrospinal fluid, particularly if the abnormality was in the first zone, multiple sclerosis was almost certain to be present or to follow in later years. In 40 cases of acute retrobulbar neuritis, Watkins found evidence of multiple sclerosis, before, coincident with or after their visual disturbances in 27 per cent. The incidence rose to 50 per cent when 18 of the cases were followed for more than three years. In 39 patients with chronic retrobulbar neuritis, with slow onset, 15 per cent proved to have multiple sclerosis. This also was the experience of Adie (Adie, W. J.: Observations on Aetiology and Symptomatology of Disseminated Sclerosis, *Brit. M. J.* 2:997-1000 [Dec. 3] 1932), who observed retrobulbar neuritis in 41 of 148 cases of multiple sclerosis. Retrobulbar neuritis, if observed in the subacute stages, is characterized by pallor of the optic disk only, usually limited to the inferotemporal third, with the other two thirds normal in color, indicating an involvement of the papillomacular bundle alone. The subject is thoroughly reviewed by Walsh (Walsh, F. B.: Clinical Neuro-Ophthalmology, Baltimore, Williams & Wilkins Company, 1947).

Loss of abdominal reflexes is also an early sign of multiple sclerosis.

## ESTIMATION OF AGE OF FETUS

**To the Editor:**—Where can I obtain information relevant to roentgen diagnosis of month or week of intrauterine pregnancy?

H. A. Weisse, M.D., Plymouth, Wis.

Answer.—As emphasized by William Snow (Clinical Roentgenology of Pregnancy, Springfield, Ill., Charles C Thomas, Publisher, 1942), various criteria have been proposed for obtaining the age of the fetus in utero from roentgen examinations. Some look for the degree of bony development and the appearance of bony epiphyses. Others use the length of one bone, while still others consider the length of the occipital frontal diameter of the skull or perimeter. Others try to gage the total length of the fetus from heel to crown. The multiplicity of methods indicates that none is entirely satisfactory. The estimates are approximate. Whenever possible, the clinical examination should be coordinated with the roentgen observations.

For greater accuracy in deriving the fetal age Snow calculates the perimeter of the skull. Paul C. Hodges determined the age of the fetus in weeks by roentgen examination from the formulas of Scammon and Calkins. He used the net perimeter of the skull from two roentgenograms taken at right angle to each other and corrected for distortion according to Ball. Snow compared his figures with a series in which he had undertaken roentgen pelvic cephalometry shortly before delivery where the pregnancy had ended prematurely and found general agreement but with sufficient variation to indicate that caution must be exercised in the use of the figures. Experience with cephalic measurements near term proves that this is much more reliable. There is no great difficulty in recognizing from such roentgen examinations the approximate age of the fetus. In Snow's book are charts showing general relationships between fetal size and fetal age and also general relationships between skull perimeter including scalp thickness, fetal age, weight and height.

## USE OF INSULIN WITH DEXTROSE INTRAVENOUSLY

**To the Editor:**—What is the rationale, if any, for one's covering the dextrose *in fluids administered intravenously with insulin in nondiabetic patients?* Does it prevent the overflow of sugar in the urine and if so is it utilized as carbohydrate by the patient? Is it stored as glycogen in the liver or does it become muscle glycogen? Please explain the physiology involved.

M.D., New York.

[This inquiry was referred to two authorities, whose respective replies follow.—Editor.]

Answer.—There is not any good reason for "covering the dextrose in fluids administered intravenously with insulin in nondiabetic patients." In fact, the addition of insulin may defeat one of the important purposes for which dextrose is given; namely, to insure a good store of liver glycogen. The nondiabetic person has an optimal amount of insulin present as far as the deposition of liver glycogen is concerned. Any exogenous insulin represents an excess, which tends to drive glycogen out of the liver and into the peripheral tissues, chiefly the skeletal muscles. Hence, while more of the administered sugar is retained, it is not held where it will do the most good. An explanation of the physiology involved may be found in the section entitled "Physiologic Basis of Intravenous Dextrose Therapy for Diseases of the Liver" on page 277 of the monograph "Carbohydrate Metabolism," by Soskin and Levine, University of Chicago Press, 1946.

Answer.—A number of writers in the past advocated the use of insulin combined with intravenous administration of dextrose in the treatment of nondiabetic patients suffering toxemias of pregnancy, ketonemic cyclic vomiting in children, toxic diphtheria, acute hepatic disease and other conditions. But in the nondiabetic subject without a deficiency of endogenous supplies of insulin and without a deficiency of insulin there is little reason to believe that extra insulin would aid or favor in any way the utilization of intravenously administered dextrose. There is, in fact, reason to fear that excessive amounts of exogenous insulin might have a deleterious effect in patients suffering toxicosis if hypoglycemia were induced. Under certain conditions overdosage of insulin has been shown to promote formation of muscle glycogen at the expense of liver glycogen.

## PREVENTION OF RHEUMATIC FEVER

**To the Editor:**—What is the present status of prevention of rheumatic fever with sulfonamide drugs or penicillin? R. S. Srigley, M.D., Hollis, Okla.

Answer.—The most frequent precipitating factor antedating the appearance of rheumatic fever is streptococcic infection of the upper respiratory tract. Numerous observers have shown that the incidence of respiratory infections in susceptible children is significantly reduced by small daily doses of sulfonamide drugs, and hence the chance of subsequent rheumatic fever is likewise lessened. It is also well known that in a certain number (perhaps 10 to 15 per cent) of children leukopenia develops and others show renal irritation during this type of therapy. For this reason a close watch on the blood and urine must be kept, especially during the first month or so of therapy, as well as at intervals thereafter. In rare instances a peculiar hypersensitivity to sulfonamide compounds may result in periarteritis nodosa, or even in an obscure form of myocarditis.

The usefulness of penicillin in combating streptococcic infection of the upper respiratory tract has been established. The daily use of this antibiotic over long periods as a protective measure is still in the exploratory stage.

## THIOCYANATE POISONING

**To the Editor:**—Is there any indication that prolonged use of potassium thiocyanate for hypertension produces anemia?

Alfred H. Weitkamp, M.D., Los Angeles.

Answer.—Potassium or other thiocyanates may give rise to a variety of acute and chronic symptoms due to the toxicity of the thiocyanate radical. In large doses it may be acutely fatal, and the prolonged administration of as little as 0.5 Gm. daily may lead to a fatal outcome. The symptoms of thiocyanate poisoning are variable and include a number resembling iodism (fever, skin reactions, goiter), weakness and fatigue, aching and cramping of the muscles, abdominal distress, nausea, diarrhea, mental confusion, aphasia, convulsions, toxic psychosis and, in cases of chronic poisoning, marked anorexia, emaciation and anemia. In animal experiments, the repeated administration of sublethal doses of the thiocyanates causes also a diminution in hemoglobin content with the development of anemia. Inasmuch as this anemia is accompanied by evidence of renal damage as well as by gastrointestinal symptoms, it is unknown whether the observed effect on the hemopoietic activity is secondary to these changes or due to direct toxic effect on the bone marrow.

## FRIGHT AND FETAL DEATH

**To the Editor:**—Is there any evidence that fright may cause fetal death at the eighth month of pregnancy, and, if there is, what is the mechanism of such death? Leon Melkonian, M.D., Gilroy, Calif.

Answer.—Evidence apparently is not available to support the belief that fright can cause death of the fetus in utero. In a toxic patient with blood pressure markedly elevated, sudden release of epinephrine theoretically might be considered to raise the blood pressure enough to cause abruptio placentae. Another theoretical consideration might be that if the fright were great enough the patient might possibly contract the abdominal muscles and diaphragm with enough force to separate the placenta. In either of these considerations prodromal signs or sequelae should demonstrate the trouble.

## ETHER IN THROMBOANGIITIS OBLITERANS

**To the Editor:**—What information have you regarding treatment of Buerger's disease (thromboangiitis obliterans) by means of ether injection in dextrose *solution? Is this practice safe?* M.D., Illinois.

Answer.—Intravenous injections of ether have been proposed for the treatment of gangrenous or pregangrenous extremities. The injection may cause a temporary vasodilatation and evanescent euphoria. Evidence that it exerts a favorable influence on the course of Buerger's disease is lacking. Its use is not devoid of side reactions.

# DEFICIENCY DISEASES IN THE CINCINNATI GENERAL HOSPITAL

## A Ten Year Study

### Chairman's Address

M. A. BLANKENHORN, M.D.
Cincinnati

From time to time within the past decade medical publications have appeared describing patients in the Cincinnati General Hospital who were ill because of vitamin deficiency. In 1942 a statistical study revealed an incidence of pellagra in that hospital similar to that reported from New Orleans; Augusta, Ga.; Birmingham, Ala.; Durham, N. C., and from other southern cities where pellagra had been regarded as a common endemic disease. Our report in 1942[1] described an incidence which began in 1935 at 0.3 per cent of all medical admissions and rose each year to 1.5 per cent in 1938. Now it has been determined that since 1939 the incidence has gradually declined so that in 1947 and 1948 there were no cases of pellagra. A personal communication from Dr. Norman Jolliffe has described a similar situation at Bellevue Hospital, New York. It was believed that there had been only an apparent increase in the disease in the community incident to increased interest in the hospital. Now with the same circumstances which determine the admission of patients and with the same methods and zeal for diagnosis—and, in fact, the same individual physicians—there has been a notable decrease.

### SCOPE OF THE STUDY

In a recent study which brought these facts about pellagra to print,[2] it was observed by the authors that the decline started before there was enriched flour or other concerted effort at dietary reform in Cincinnati. There was as elsewhere a change in business, employment and wages, the effects of which are profound but not directly measurable on the type of person furnishing most of the hospital admissions. Beriberi and also scurvy have been closely studied in the same period, but a similar decline has not been observed. Without attempting to explain why the incidence of deficiency diseases fluctuates in this manner, I propose herein to describe all of them that have been diagnosed in the past ten years, together with some of the medical, social and economic factors which, as I see them, may be concerned in nutrition and the public health. From 1939 to 1948, on a service which admits about 200 patients a month, pellagra has been diagnosed in 106 persons, beriberi in 48, scurvy in 33, riboflavin deficiency as cheilosis in 14, sprue in 4, vitamin A deficiency in 1 and vitamin D deficiency in 1. It cannot be stated how many of these patients were admitted solely for the deficiency disease which was eventually diagnosed. Many were admitted for a variety of other conditions, acute and chronic, and the deficiency disease was found to be a sequel or incidental to the other illness. During the entire period no special medical service such as a nutritional ward was maintained, and the continuous demand for hospital beds has made the admission of patients with minor though interesting forms of disease almost impossible. There has never been a routine laboratory test or screening method for case finding. The usual bedside clinical examination has been the method in continuous use for diagnosis, with laboratory devices used secondarily and for confirmation. Only cases observed on the medical wards are here described, although a few were discovered on other services in the routine of consultations. When treatment required it, the patients were transferred.

In vitamin B deficiency syndromes, house officers have considerable difficulty with the decision as to which of several diagnoses should be considered primary, or the leading cause for disability. In such dilemmas in which the two diseases, pellagra and beriberi, are present no patient has been counted twice in this study of incidence. However, some patients may on readmission have been found with a different disease—for example, scurvy.

The diagnosis of pellagra was established by observation of characteristic symmetric dermatitis, usually of the hands or feet, or both, and glossitis.

### PELLAGRA

There were 106 patients whose disease was diagnosed as pellagra; 68 were white, 38 were Negro; 58 were men, 48 were women; the oldest was 84, the youngest was 20; the mean average age was 53.6 years; in 33 pellagra was caused by alcoholism; in 66, by some other disease, acute or chronic. These diseases were in the main of the same nature as those indicated in an article on secondary pellagra, published in 1944 in *Medicine*.[3] It should be restated now that there are no distinguishing features in various stages of the disease. Pellagra is pellagra, and at this hospital the term secondary pellagra is no longer used. Study

[2] Bean, W. B.; Vilter, R. W., and Blankenhorn, M. A.: The Incidence of Pellagra in the Cincinnati General Hospital, 1935-1947, J. A. M. A. **140**:872 (July 9) 1949.

[3] Bean, W. B.; Spies, T. D., and Blankenhorn, M. A.: Secondary Pellagra, Medicine **23**:1, 1944.

of these patients now throws no light on the pathogenesis of pellagra other than that observed in 1942. In only 16 patients could no cause for the disease be determined; hence it must be assumed that poverty and ignorance in matters of diet were the cause. Ignorance has proved a difficult etiologic factor to assess, qualitatively or quantitatively, but in the matter of dietary habits it has been determined that many patients prefer cornbread, fat meat and well boiled greens, as in so-called southern cooking. Of 106 patients, exactly 53 were born south of the Mason and Dixon line and were presumed to be accustomed to southern cooking. In this ten year period one half of all medical patients were born in the South. I believe the dietary habits prevalent in Cincinnati among those of southern origin have much to do with the high incidence of pellagra, but it is difficult to put the matter to a test.

Poverty is perhaps equally difficult to study. Cincinnati has it, but it is no worse than in comparable cities. During the ten year period employment and wages have steadily risen; so has the cost of food in almost parallel manner. Since many of our patients were unemployable, their poverty became greater as living costs became higher. The cost of all food rose from a price index of 95.2 in 1939 to 209.7 in 1948—120 per cent. The cost of greens, which may be considered essential to diet and may be chosen as a characteristic protective food, rose from an index of 0.045 to 0.135, or 200 per cent. Lean meat is equally important in the prevention of pellagra, and the cost of it certainly is a factor in its distribution and consumption. In Cincinnati the cost of lean meat (hamburger steak) has risen nearly 300 per cent in the same time that the incidence of pellagra has diminished. It is impossible to learn the actual consumption of these food items by the persons who are admitted to the Cincinnati General Hospital. A dietary history is taken in all instances, but this is unreliable except when done by an expert, who is not always available. It can be shown that in recent years it has become more difficult to buy pellagra-preventing foods than food in general. Enriched flour began to be used in this city in 1941, and, by 1943, 90 per cent of all the flour consumed was enriched.

Forty-four of the 106 pellagrins also had other specific deficiency diseases; for example, neuritis, cheilosis, vitamin A deficiency and scurvy. Many were found also with Wernicke's syndrome (presbyophrenia), hypertrophic or atrophic gastritis, hyperchromic anemia and hypoproteinemia—but these manifestations are considered essential to pellagra and therefore are not listed among the forty-four associated deficiency diseases. I do not include either delirium tremens or cirrhosis of the liver as an associated deficiency. There were only 8 patients with cirrhosis as an associated disease, which seems remarkable, because 33 of 106 pellagrins were chronic alcoholic addicts and had been on poor diets for a long time. In our 1942 report of collected literature cirrhosis was found to be a common cause of so-called secondary pellagra. Twenty-nine of the 106 patients died in the hospital, and 19 necropsies were performed. Altogether, complete study failed to disclose an obvious cause for death in 9 cases. It should be noted that none of the lesions of pellagra are, anatomically speaking, regarded as lethal. These 9 deaths were ascribed, then, to the prolonged and severe effects of malnutrition and to nothing else. In several cases the heart was enlarged rather than smaller, as is usual in cases of starvation. In none of this group had the diagnosis of beriberi heart been made, but it could not be excluded. Of especial interest are the 16 patients in whom chronic associated disease and/or alcoholism were not discovered; i. e., those who fell into poor dietary habits because of ignorance and poverty. Ten were born in the South. They had been long resident in Cincinnati and were comparable in age to the entire group. Four died and 3 were examined post mortem; all 3 exhibited no cause for death other than pellagra. The fatality rate, 27 per cent for this group of 106 patients, is necessarily high because of their associated diseases and chronic alcoholism. In cases of uncomplicated pellagra there were 4 deaths; i. e., a fatality rate of 25 per cent. This apparent failure of treatment was due to the severity and advanced stage of the disease, because nicotinic acid or nicotinamide were freely used in conjunction with good diet.

### BERIBERI

The diagnosis of beriberi (neuritis due to thiamine deficiency) was made in 48 subjects exclusive of the patients with pellagra as the chief disease and berberi as an associated disorder. Of the 48, 45 were white, 3 were Negro; 34 were men, 14 were women; the youngest was 27, the oldest was 76; the mean average age was 53 years. Of the diagnostic criteria described by Aring and Spies,[4] absent or decreased tendon reflexes with tenderness of the nerve trunks and sensory changes were always observed. Few patients were paralyzed, and none remained paralyzed for long after treatment was started. Sixteen were found to have beriberi heart according to the criteria published by me in 1945 and again in 1947 in association with C. Vilter[5]: (1) enlarged heart with sinus rhythm; (2) dependent edema; (3) elevated venous pressure; (4) minimal electrocardiographic changes; (5) absence of all other causes of heart disease; (6) history of three or more months of a diet deficient in thiamine; (7) signs of neuritis or pellagra, and (8) recovery with decrease in heart size or observations at autopsy consistent with beriberi heart. Of the 48, 24 were classed as chronic alcoholic addicts and 19 as ill with other disease of a wasting nature, leaving 6 in whom no cause for the pellagra was discovered. Fifteen patients displayed other deficiency disease, and 4 had only cirrhosis. Nine had forms of cardiac disease other than beriberi heart. Eighteen died, a fatality rate of 37 per cent. Eleven necropsies were performed. In this as in the pellagra group, fatality rates were high because of severe associated disease, prolonged alcoholism and severe beriberi. Deaths from delirium tremens are not recorded in this group. In a number of instances no obvious cause for death was apparent; i. e., as morbid anatomy of gross nature. In some patients death was sudden and unforeseen. Vilter and I described patients in this group as subject to syncopal attacks and unexpected death.

### SCURVY

Adult scurvy was diagnosed 33 times, with the criteria described by R. Vilter[6]: large cutaneous hemorrhages; hemorrhagic follicular keratosis and hemorrhagic gingivitis, and anemia, all of a type which are the classic signs of severe adult scurvy. Of the 33 patients, 31 were white and 2 were Negro; 29 were men, 4 were women; the youngest was 16, the oldest was 79; the mean average age was 61.5. Only 5 of the 33 were born in the South. There was chronic alcoholism in 5, associated disease in 13 and no known cause in 15. The associated diseases were similar to those described in association with pellagra. There were associated deficiency states, also principally due to lack of thiamine. There was but 1 patient with cirrhosis. Six died—a fatality rate of 18 per cent. It is notable that in 3 instances the cause of death could not be designated at necropsy. In each, beriberi heart could have been present but was not diagnosed because the usual criteria were wanting, but scorbutic hemorrhage was not the cause of death. A search of the social history in this group reveals that almost all of the patients were white men over 60 years of age who lived alone as recluses or on scanty income in a cheap lodging, where they did their own cooking. They were not especially addicted to alcohol, but they did not eat fruit or uncooked vegetables. There was no particular seasonal incidence (months). They were not habituated to southern diet. Many had not lost weight but had gradually become weak, mentally depressed and, eventually, confused; their neighbors or the police brought them to the hospital. The incidence of adult scurvy has risen from zero in 1939, 1940 and 1941 to an index of 0.38 in 1945. It has declined only slightly in 1946, 1947 and 1948, but not to the extent to which pellagra has. Meanwhile, the cost of citrus fruits has dropped 20 per cent from 1939 to 1948. It is obvious that the relative cost of avoiding scurvy has not increased but has indeed decreased. Meanwhile, the incidence has not declined as has that of pellagra. Associates and I are of the opinion that living habits are mainly responsible for the ill health of these persons.

### OTHER DEFICIENCY DISEASES

Riboflavin deficiency is such a poorly defined disease that I shall give it but brief mention. The diagnosis was made on this service when a patient displayed angular cheilosis, conjunctivitis and a magenta-colored glossitis. This disease was diagnosed in 14 persons who were probably mildly ill with pellagra but were without symmetric dermatitis. Now with greater criticism or perhaps clinical skepticism, the disease either has become rare in Cincinnati or is ignored. The decision about magenta coloration is difficult; the conjunctivitis and cheilosis are not specific, nor do they respond specifically to treatment.

Sprue, vitamin A deficiency and vitamin D deficiency are so uncommon that they need only be listed as rare.

### SUMMARY

Pellagra in the Cincinnati General Hospital has declined from an incidence in late 1930 and early 1940 of 1.2 per cent to a low of few or no cases in 1947 and 1948. The cause of this decline is obscure. It started before use of enriched flour became general and has continued despite the rising cost of food and especially the greater rise in the cost of greens and lean meat. The probable cause of the decline is dietary reform initiated by public health education and continued by the use of enriched flour. Pellagra occurred mainly in white persons, about equally in men and women. Assuming that poor diet is the cause, debilitating disease was contributory in more than half the cases, chronic alcoholism in a third. In 15 per cent of patients no cause for the disease other than a poor diet was discovered. One half of all pellagrins were born in the South and probably were accustomed to a diet low in thiamine and nicotinic acid. The fatality rate of the group was 27 per cent.

Beriberi occurred mainly in white men in the middle fifties and occasionally in women. Assuming that thiamine deficiency is the cause, chronic alcoholism was a contributary cause in 50 per cent and other disease in 37.5 per cent; the beriberi was without apparent cause in 12.5 per cent of patients. In 33.33 per cent there was beriberi heart. The fatality rate of the entire group was 37 per cent.

Scurvy occurred almost entirely in old men over 60 who lived alone or in lodgings. Chronic alcoholism and other disease were additional causes in less than one half. Dietary habit and poverty were the most frequent causes of the disease. The fatality rate was 18 per cent.

One half of the deficiency disease observed in the Cincinnati General Hospital was caused by other acute and chronic disease, and one third by chronic alcoholism. There has been decided reduction in the incidence of pellagra. This reduction is probably the result of dietary reform and the enrichment of flour. Beriberi has been reduced little and scurvy less.

---

# ARTANE® THERAPY FOR PARKINSONISM

## A Preliminary Study of Results in One Hundred and Seventeen Cases

LEWIS J. DOSHAY, M.D.
and
KATE CONSTABLE, M.D.
New York

Trihexyphenidyl (artane,® 3-[1-piperidyl]-1-phenyl-1-cyclohexyl-1-propanol hydrochloride) is a member of a new series of antispasmodic compounds.[1] After intensive pharmacologic investigation [2] of its effects and of reactions to the drug in animals, the product was turned over to us for clinical evaluation. Its effects were carefully studied in a series of 117 cases of Parkinson's disease. (Since the preparation of the paper, the drug has been employed by us in some 150 additional cases with favorable results, but the observations were not available in time to be incorporated with the earlier cases.) Embodied in this report are the method of administration and use of trihexyphenidyl, correlated with the results of the therapy and the reactions of the patients.

The drug has been under study at several other clinics, and, although a detailed comparison of such data with our own has not yet been made, verbal reports are to the effect that other results fairly closely coincide with our own.

In an article published by one of us two years ago,[3] special attention was drawn to the need that exists for new preparations to be added to those regularly employed in the treatment of parkinsonism. The

[2] Artane® was developed by Lederle Laboratories, Division of the American Cyanamid Company.

[3] Doshay, L. J.: Recent Trends in the Treatment of Parkinsonism, M. Rec. **160:** 339, 1947.

standard drugs to which reference was made include: scopolamine, stramonium, atropine, Bulgarian belladonna, rabellon® (a tablet containing belladonna alkaloids) and vinobel® (a tablet containing the alkaloids of belladonna root obtained by extraction with wine). In the light of this manifest need, the success which has attended the use of artane® is highly gratifying.

Parkinsonism has been an important and challenging problem to the neurologist for the past thirty years. Prior to 1918, parkinsonism was chiefly of the arteriosclerotic variety and as such did not pose too great a problem in terms of treatment, which essentially embraced hyoscine, stramonium and potassium iodide. However, the span of life has been materially lengthened in recent decades by the marvelous advances of medical science, so that we are becoming confronted with ever-increasing numbers of such cases.

In particular, however, the epidemics of encephalitis of 1918-1921 contributed a new and grave situation.[4] All efforts during the twenties were confined to the discovery of a vaccine that would successfully prevent encephalitis or check its course and symptoms. The effort failed.[5] Attention thereupon shifted toward the maximum exploration of various plant extracts to combat the symptoms of rigidity, oculogyria and tremor. It thus happened that Bulgarian belladonna was heralded with great promise in the thirties.[6] Although this drug failed to fulfil original expectations, it has nevertheless continued in use as a good adjunct in the treatment of Parkinson's disease, along with such other products as atropine and various alkaloids of belladonna.

During the past decade surgery made a strong bid for the relief of parkinsonism, but results thus far have proved sadly disappointing, because the determining site of the pathologic basis of tremor and rigidity remains unknown, rendering it difficult to know where and what to cut. Under the circumstances, it is not surprising that some surgeons operate on the subcortex, others on the lenticular nucleus or the pallidofugal tracts and still others on the spinal cord.[7] This ceaseless search to find relief for those who suffer with Parkinson's disease leads to the present era of synthetic drugs.

### PHARMACOLOGIC PROPERTIES OF TRIHEXYPHENIDYL

Artane® is the trade name given to the synthetic product 275 C, which bears the structural formula of 3-(1-piperidyl)-1-phenyl-1-cyclohexyl-1-propanol hydrochloride and the generic name trihexyphenidyl. It was carefully tested, along with five other closely related synthetic products, for comparative determinations of their antispasmodic activities, pharmacologic effects and toxic reactions in relation to known drugs such as atropine and trasentin® (diphenylacetyldiethylaminoethanol hydrochloride). Six months of such experimentation with large numbers of various laboratory animals proved that trihexyphenidyl has greater antispasmodic qualities than any of the other five synthetic products and in this regard is twenty times as effective as trasentin® and half as effective as atropine. Similar to all antispasmodic drugs, the compound leads to cerebral excitation, but unlike the other five piperidyl derivatives it does not lead to convulsions, even under massive dosage. It has about half of the mydriatic and an eighth of the antisialogogue potency of atropine, and the inhibition of the cardiac vagus is only one-hundredth that of atropine. Lastly, it has no ill effects on blood pressure, respirations, blood cell count, kidneys, liver, metabolism of sugar, growth or reproduction in dogs, cats, rabbits, guinea pigs and rats. On the basis of the observations, it is evident that the compound possesses large elements of the favorable effects of atropine, without its dangerous components.

Use of trihexyphenidyl in the treatment of parkinsonism was suggested by an analysis of its pharmacologic properties in animals.[8] At this point we commenced trial of the product with our patients. By January 1948 its effects and reactions had been closely checked in some 20 patients with Parkinson's disease. Since then the series has rapidly expanded to include at present almost 270 cases, although for reasons previously stated we are reporting on only 117 cases, which have been followed most thoroughly and for the longest period.

### METHOD OF ADMINISTRATION

Trihexyphenidyl was supplied in scored tablets of two sizes, 2 mg. and 5 mg., thus facilitating the administration in doses of 1, 2, 2.5 and 5 mg.

It was found that in postencephalitic parkinsonism larger doses are necessary than in arteriosclerotic or idiopathic forms of the disease. This observation was not unexpected, because the drug has properties similar to those of atropine, to which, according to common experience, postencephalitic patients present high tolerance.[9]

In mild and only moderately advanced cases one should start with a dosage of 1 or 2 mg. twice a day, increasing it to three or four times a day, as the condition and response of the patient warrants.

Since nearly all postencephalitic patients suffer from varying degrees of sialorrhea, it was found that antecibum administration was more effective among them. In cases in which tremor was the most disturbing symptom it was necessary to add a small dose of scopolamine to the trihexyphenidyl. In advanced cases, in which patients have become accustomed to large doses of other drug, we have at times found it desirable to start with half of a 5 mg. tablet of the compound two or three times a day, while reducing the high dosage of the drug which the patient has been taking and thus gradually changing over to trihexyphenidyl alone. Thus a patient has been changed not suddenly but gradually from Bulgarian belladonna or a proprietary alkaloid of belladonna to trihexyphenidyl. In postencephalitic patients with excessive sialorrhea and rigidity, small amounts of atropine solution may need to be added.[10]

Trihexyphenidyl has been used in the idiopathic group in approximately the same manner and dosage as with postencephalitic patients. Since many of the former group have also some degree of sialorrhea, antecibum administration of the drug is likewise favored. By suitable adjustment of the dose to tolerance, these patients do well on the compound. Even so, the following rule should be adhered to in the treatment of all patients with parkinsonism: Since we have no cure for them, and there is none in the offing, the purpose of all available therapy should be to render the patient as happy, active and useful as possible. Hence, it is never wise to force a new remedy on a patient who is content with his present regimen of treatment.

The drug is effective in the arteriosclerotic group in smaller doses than in the postencephalitic. Many patients are comfortable on a dosage of 1 mg. two or three times a day. The dosage can then be raised gradually to the optimum level for the particular patient. Since sialorrhea is not so often a factor in the arteriosclerotic type, the drug is better administered post cibum. If the patient is especially sensitive to the drug, one 2 mg. tablet may be broken into pieces and administered over a period of several hours in the day If tremor is pronounced, it may be necessary to supplement the compound with small amounts of scopolamine, but seldom is it necessary to add belladonna for this age group. Use of atropine is contraindicated among these older patients. In some arteriosclerotic patients as much as 10 to 15 mg. of trihexyphenidyl may be necessary to provide the desired results; even this amount is well tolerated.

Physical therapy is a most valuable adjunct to the use of the compound. With his general sense of well-being improved by the drug, the patient becomes more amenable to the suggestion that he make the most of his improvement by accepting the additional help which can be derived from consistent and regular passive and active muscular reeducation. In fact, those patients who have profited most from the drug and who have maintained their level of improvement and continued to improve have as a general rule been those who were able and willing to supplement the medical regimen with various forms of physical therapy and exercises.

No special precautions are necessary in the administration of trihexyphenidyl. Our experience has been that it is an unusually mild drug, overdosage of which is almost impossible. It works its benefit without noxious side effects. It will be shown that the side reactions from the use of the compound are minimal, as compared with those of other drugs employed in the treatment of parkinsonism. The reactions seldom become disturbing to the patient, and they tend to wear off with continued use.

Though the usual dosage is between 6 to 10 mg. a day, 15 to 20 mg. is easily tolerated and doses of 30 to 50 mg. have not had deleterious effects. Complete blood cell counts in over 50 per cent of the 117 patients who were studied failed to reveal abnormal changes.

The presence of hypertension, cyanotic induration of the liver or renal disorders does not contraindicate the use of the drug, as the following case will illustrate:

CASE 1.—A. K., a man aged 59, had a tremor in his left arm when he was 50 years of age. The syndrome progressed rapidly; the left side became rigid, followed by involvement of the right extremities, neck and trunk. There was some drowsiness and sialorrhea. He spoke in a monotone. There was no diplopia, strabismus, weakness of convergence, nuclear palsy or oculogyria. The clinical picture was typical of idiopathic parkinsonism. Over a period of years he was maintained at first on small amounts of atropine and later on Bulgarian belladonna, rabellon,® scopolamine and vinobel.® He would remain stationary for long periods, with minor fluctuations in his condition. He was able to get about slowly, although he required help with dressing. On rare occasions he would smile, but for the most part he remained disgruntled, irritable and depressed.

At the age of 55 years there developed otosclerosis and gradual evidence of cerebral and generalized arteriosclerosis. Albumin and casts appeared in the urine, and his blood pressure rose to 200 mm. systolic. He began to complain of headache, vertigo and tinnitus. Edema of the ankles and legs developed, necessitating the recurrent administration of intravenous mercurial compounds. For the past four years he spent the winters in Florida.

In December 1947 belladonna and scopolamine were discontinued by a local physician, with the result that the patient became, as his family described it, "stone rigid" and was unable to chew, swallow or speak. He was then placed in a mental institution, where he was fed fluids intravenously, lost considerable weight and was considered moribund.

At this point he was placed on trihexyphenidyl therapy, 2 mg. three times a day. There was almost immediate improvement. He began to eat, talk and smile. He soon progressed to dressing and shaving himself. He gained weight and seemed a changed man. He was admitted to the Neurological Institute in April 1948 for a short period of observation and was found to be much improved over his condition of a year before. On examination, no pyramidal signs were found but there was a slight increase in the Achilles tendon reflex on the left. There was no drowsiness. His expression was good and his eyes alert; the bilateral tremor of the year previous, as well as rigidity with cogwheel movements, were all definitely diminished. In May 1948 Bulgarian belladonna was added to the medical regimen, and to date this dosage has not needed to be increased.

The most profound change in the man has been his mental improvement. Previously, because of tenseness and restlessness, he could not maintain any position for long and continually demanded that his legs and arms be stretched and his position changed. He berated his family for lack of sympathy and complained of constant pain and suffering throughout his body. He moaned, cried and was full of self pity.

Under trihexyphenidyl therapy his mental attitude became entirely different. He was able to sit quietly, calmly and fairly relaxed for hours at a time. He was again able to eat at table with his family and complained no longer of pains in muscles and joints. There has been no more groaning or crying.

The effect of the drug in this case was obviously not due to a reversal of the original pathologic conditions, but to a symptomatic change in the bodily and mental expression of the basic disease. Nevertheless, temporary and supportive as this treatment may be, it brings great relief to a patient suffering from a chronic progressive disease.

The distinguishing clinical features of the three essential types of parkinsonism, postencephalitic, idiopathic (formerly and erroneously called paralysis agitans) and arteriosclerotic, are so well differentiated and simple to recognize that they should be familiar to every one, especially since patients belonging to these groups differ in their response and reaction to drugs. A summary of the distribution of the salient symptoms characteristic of the three types of parkinsonism enables one to visualize the diagnostic criteria that characterize each group.

### THERAPEUTIC EFFECTS OF THE DRUG

There were 75 men and 42 women in the series under study, with the youngest among them 25 years of age and the oldest 78. Although it is a common observation that patients with parkinsonism tend to tire of any remedy and to engage in an endless search for something better, it was encouraging to find that 80 per cent of the patients who have been placed on trihexyphenidyl therapy have continued it month after month, without desire to change to another drug and without expressions of dissatisfaction.

In order to abstain from rough estimations of precise degrees of improvement, it was considered advisable to employ only the two categories of "improved" and "unimproved" to express our results. Patients were classed as improved if the symptoms were lessened to any appreciable degree or if the patient's comfort and well-being were bettered. If the patient derived no relief or expressed a desire to change to another medicament he was classified as unimproved. Since there were no patients actually retarded by the treatment, there was no basis for employing the designation "made worse."

Parkinsonism is a chronic progressive disease, and experience teaches that one is not justified in utilizing minute shades of change to record the results of treatment, such as near cure, remarkably improved, much improved, moderately improved and slightly improved. Besides, in many of the so-called "near cures," in which initial effects of the drug appear remarkable, improvement tends to lessen with time. Moreover, on discontinuation of the treatment all benefits cease. It is desirable, therefore, in reporting the value of any treatment in such chronic and long-continued illness, to refrain from overenthusiastic conclusions based on one small cross section of time. Therefore, although almost unbelievable improvement was obtained with the compound in many instances, it was considered desirable to classify even these patients under the unmodified designation of "improved."

It will be noted that 76.1 per cent of the patients treated with the drug were improved and 23.9 per cent unimproved.

Although the figures alone are most gratifying, they hardly serve to convey the full measure of benefits which patients derived from use of the drug. For this, we shall briefly cite some case histories that were not specially selected but taken from a small alphabetic list of patients receiving the compound.

Case 2.—B. G., a woman aged 55, had acute encephalitis in 1928. This was followed by slowly progressive rigidity, slight tremor and lethargy. In 1945 curare was tried at Duke University with little effect on the rigidity. She tolerated scopolamine and stramonium poorly and in August 1947 was started on trihexyphenidyl therapy. She moves more freely, drives her car, looks brighter, is less depressed, swallows more easily and has gained weight. Her improvement continues satisfactory ot date.

Case 3.—C. G., a man aged 34, noted the development of progressive stiffness and some tremor in the course of the last four years. There was no available history of a preceding acute illness. Examination revealed slight strabismus, weakness of ocular convergence and lethargy. He had been treated with various belladonna preparations. On trihexyphenidyl he has obtained improvement. He is more cheerful; the rigidity is less; his speech is clearer, and he is generally more alert and active.

Case 4.—L. G. is a man aged 47 whose postencephalitic parkinsonism symptoms started in 1932 and progressed to an advanced state of rigidity and tremor, torticollis, lethargy, sialorrhea and oculogyria. In 1943 he underwent cerebral surgery without improvement in his rigidity or tremor. In fact, the latter had become worse so rapidly that massive doses of scopolamine were necessary to afford the patient some temporary relief. In January 1948 trihexyphenidyl therapy was begun, and he gradually discontinued the use of all scopolamine. The tremor has lessened, and the oculogyric crises have ceased.

Case 5.—M. G., a man aged 62, had tremor and rigidity of three years' standing. He had been receiving the usual medicaments for this age group. In March 1948 he was placed on trihexyphenidyl therapy, and it has made him happier than all previous treatment measures. He eats and sleeps well; he walks easier, and the tremor is less.

Case 6.—R. G., a man aged 44, had encephalitis in 1918, followed by increasing rigidity, tremor and oculogyric crises. He had been under the care of the Matheson Commission for the study of encephalitis in 1929 and had received encephalitis vaccine and most of the other known forms of treatment. He was placed on trihexyphenidyl therapy in January 1948, with the result that he is more cheerful than he has been in years and has few oculogyric crises. The tremor is slightly less, and he moves easier.

Case 7.—R. G., a woman aged 63, had progressive tremor and rigidity of four years' standing. Scopolamine and belladonna produced dizziness, drowsiness and general weakness, so that she had discontinued all medicaments the previous year. In June 1948 she was given the new drug. She walks easier, feels better mentally and has little tremor.

Case 8.—S. G., a man aged 40, in 1939 noted the development of stiffness in the right arm. This was followed by tremor, increasing rigidity, sialorrhea, impaired speech, depression and thoughts of suicide. He has been receiving the compound for seven months, with little change in the physical symptoms, but his nervousness and tremor have subsided. He is calmer and more relaxed and partakes of a busy program of activities.

Although parkinsonism is a chronic progressive disease, it must not be assumed that the course is of necessity always rapidly or steadily downhill. There are patients who under suitable treatment remain stationary for as long as ten or fifteen years, as the following case illustrates:

Case 9.—G. K., a man aged 40, had an acute attack of encephalitis in 1929 at the age of 19, and shortly afterward there developed rigidity of the muscles of the neck and arms and periodic attacks of oculogyria. These became so frequent that he feared the loss of civil service employment. Early in the course of his illness scopolamine and stramonium had been tried and failed to bring any relief. On atropine, however, which he had been taking for the past twelve years, there was complete control of the oculogyric crises and a regain of freedom of bodily movement, with a lessening of spasticity. His improvement continued until 1947 when, despite increases in atropine dosage, the oculogyria and body rigidity returned in severe form, so that he was forced to give up employment. Trihexyphenidyl was prescribed in the Spring of 1948 and brought him some measure of relief. However, it did not materially alter the recent rapid progress of the symptoms. Parpanit® (diethylaminoethyl-1-phenylcyclopentane-1-carboxylate hydrochloride), diethazine hydrochloride (diparcol,® diethylaminoethyl-thiodiphenylamine) and other nerve preparations proved equally ineffectual.

The explanation for the period of twelve years in which the patient's disease remained in status quo is not attempted. Obviously, atropine could not be responsible for a reversal of pathologic processes in the interstitial nucleus and substantia nigra. It could, however, have modified the effects of the pathologic condition on the peripheral structures and exercised a stimulating action on the prefrontal cortex, so that the progress of the disease seemed to be stopped for a long time.

The reappearance of symptoms after an interval of twelve years may have been a sudden advance in pathologic changes or the result of increased tolerance of the body tissues to the drug, with loss of its long beneficial effect. Because it is the general experience that the effects of drugs do tend to decrease with use, the need for ever new and more effective medicaments is granted. In the long drawn out course of parkinsonism, patients regularly tire of one drug after another, so that it becomes necessary for the physician to have his armamentarium continually renewed. Also, one finds that some patients tolerate better one drug, others another. Atropine, for example, while a valuable medicament in many cases of postencephalitic parkinsonism, is unsafe in the older arteriosclerotic group, because of the hazard of precipitating glaucoma and other disturbing circulatory and visceral phenomena.

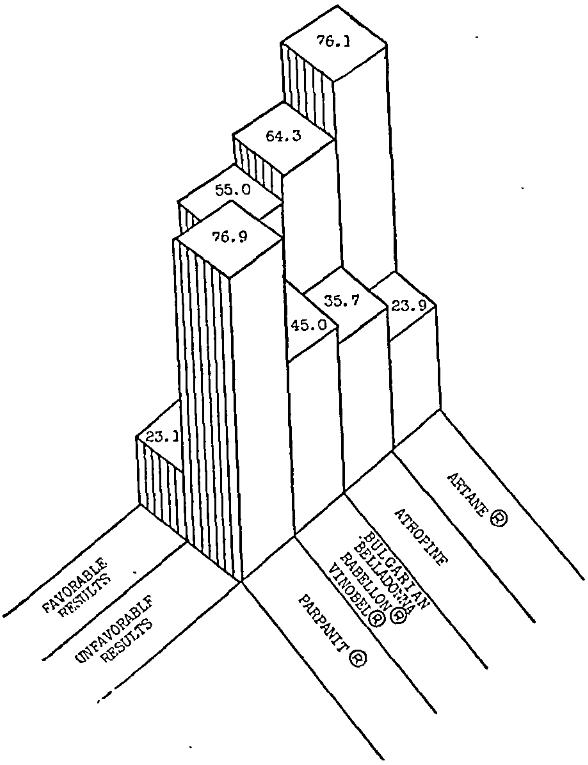

Chart 1.—Percentages of favorable and unfavorable results among different preparations employed in the treatment of parkinsonism.

Trihexyphenidyl, with its similarity to atropine but without the toxic side reactions of the latter, has proved a valuable adjunct in the treatment of arteriosclerotic parkinsonism and of the idiopathic variety. A favorable response to treatment has been observed more frequently among members of these two groups than among the postencephalitic patients. Chart 1 shows that the drug afforded as much symptomatic relief to sufferers with parkinsonism as did any other available drug.

In addition to the physical improvement, the mental stimulation which the compound affords has served to successfully counteract impatience, discouragement and depression, which are common byproducts of any chronic illness. Many patients receiving trihexyphenidyl were able to carry on with their work better and with more feeling of satisfaction, whether laborer, housewife or shopkeeper. The women found their household chores easier. Rigidity was improved, and tremor and oculogyria were either controlled or lessened. Even patients with advanced symptoms of twenty years' duration were helped greatly by being made more comfortable and able to assume some care of their persons, which previously had become the responsibility wholly of their families or caretakers. In this respect the drug is of more extensive value than atropine, which is of benefit to persons with early postencephalitic manifestations but far less helpful to those whose disease is of long standing.[11] Trihexyphenidyl, in contrast, proved almost as beneficial to postencephalitic patients with over ten years' duration of illness as to those with more recent symptoms (72 per cent; 75 per cent).

### UNTOWARD SIDE REACTIONS OF THE DRUG

Experience with the use of various drugs in the treatment of parkinsonism proves that patients react differently to any given drug, depending on the type, duration and degree of illness and the age, temperament, mental attitude and constitutional makeup of the patient. Thus, it is common observation that some patients disregard dryness of the mouth or try on their own to relieve it by simple means, while others complain so bitterly that it becomes an obstacle in the treatment.

Atropine, for example, which produces pronounced dryness as well as complete cycloplegia, is tolerated well by postencephalitic subjects, who generally suffer from appreciable sialorrhea. In fact, many of these patients measure the merits of any drug by its drying effect. The compound being studied produces minimal dryness (actually 12 per cent that of atropine), and only 14 of the 117 patients brought complaint on this account. Our experience has been that 90 per cent of all patients will manage to counteract or disregard a moderate amount of dryness and blurring of vision, if these are not accompanied with more disturbing types of reaction. For a summary of the mild as well as the disturbing types of reaction from this and other drugs, see chart 2.

Nausea and vomiting may be danger signals of idiosyncrasy or approaching toxicity, but they may be caused by psychic factors, food dyscrasias or gastrointestinal infection. Moreover, some patients will experiment on their own with larger quantities than prescribed or with additional drugs. Nevertheless,

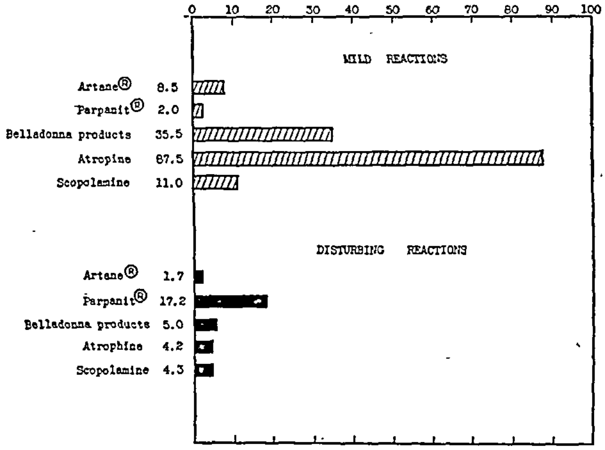

Chart 2.—Percentage of mild reactions (dryness of mouth and blurred vision) and disturbing reactions (dizziness, tachycardia, prostration, nausea and depression) among different drugs employed in the treatment of parkinsonism.

---

[11] Doshay, L. J.: Graphic Rigidity Index, J. Mt. Sinai Hosp. 5: 451, 1938.

until another cause for the symptoms has been determined, nausea and vomiting should regularly be considered serious and administration of the drug should be discontinued, or the dosage reduced, until better tolerance is effected.

Atropine is the only one among the standard drugs which causes disturbing gastrointestinal symptoms. One case of vomiting was encountered among the 117 patients on trihexyphenidyl therapy, and this was of only moderate degree and occurred in a patient with psychiatric symptoms.

Giddiness or dizziness is usually the result of sudden circulatory disturbance or fall in blood pressure, in reaction to a drug. It is most apt to occur among arteriosclerotic persons. Although the patient often becomes greatly alarmed by the symptom, there is actually no danger. Nevertheless it is an indication for reduction of medication. By the same token, tachycardia is a distressing symptom to some patients. Since it is usually disregarded and unreported by the younger persons with postencephalitic disease, it appears with comparatively greater frequency among the older patients. Tachycardia did not appear among any of the subjects receiving artane.®

Adynamia, or prostration, is a reaction, caused by the curare-like effects of a drug, which is of disturbing proportion to older patients. It is often accompanied with a large psychic component, with the patient complaining that he felt "paralyzed" and powerless to move for days at a time. Mental depression is listed as a reaction among patients, when they become unduly agitated and depressed by one or more of the foregoing unpleasant side effects of the drug, or when they become discouraged by the failure of results from a given therapy.

Aside from these, it can be safely stated that all other reactions deriving from the use of the standard drugs are sufficiently mild to constitute no hazard to the health and welfare of the patient. However, since the aim of treatment in parkinsonism is not only to achieve physical improvement but to bring greater contentment and peace of mind to the patients, it will be obvious that the less unpleasant the reactions produced by the drug the better the cooperation and results. In this respect the compound stands out, because it is so mild and so slightly disturbing to the patients that they gladly turn to it, in order to escape the side reactions experienced after use of some of the other drugs.

Because it is well tolerated by young and old and is almost entirely devoid of toxic reactions, trihexyphenidyl has earned for itself an undisputed place in the armamentarium for the treatment of parkinsonian conditions.

Finally, it remains to be noted that, with due allowance for the disappointments in results with vaccines, plant extracts and surgical measures, synthetic drugs have at long last come to the fore to bring hope and promise to those who have parkinsonism. Trihexyphenidyl, a synthetic drug, has been proved in this study to be able to do as much and more for these patients, than all existing forms of treatment. On this basis rises the prospect that in the near future still more and better synthetic preparations will become available, which may ultimately spell complete relief from tremor, rigidity and oculogyria.

## SUMMARY

1. Trihexyphenidyl (artane,® 3-[1-piperidyl]-1-phenyl-1-cyclohexyl-1-propanol hydrochloride) is a new synthetic, antispasmodic drug for the treatment of parkinsonism.

2. Extensive pharmacologic tests with laboratory animals proved that action of the drug mildly resembles that of atropine in the control of sialorrhea, in cycloplegic effects and cerebral stimulation. However, it is entirely free of the toxic effects of atropine on the cardiac vagus, blood pressure and circulation.

3. The results of clinical studies in a series of 117 patients treated with this agent, establish its great usefulness against parkinsonian disorders and its remarkable freedom from disturbing side reactions. The investigation was conducted with 47 postencephalitic, 33 idiopathic and 37 arteriosclerotic cases of parkinsonism, for periods ranging from six months to two years.

4. The drug was found on all scores to be a valuable addition to the drugs already in use for the treatment of parkinsonism. Besides the peripheral effects, common to other drugs, it has an unusual cerebral-stimulating action, which is particularly effective in combating the depression and inertia prevalent among these patients. It is, moreover, so remarkably devoid of toxic reactions that it is safe for use by the young and the old, the ambulatory and the infirm, the hypertensive, the cardiac and the nephritic. It recommends itself as the drug of choice in arteriosclerotic and idiopathic cases, and should be regularly tried in postencephalitic cases in which atropine or other forms of medication prove disturbing or ineffectual. As with other drugs, this compound is more effective when its use is combined with physical therapy and exercises.

700 West 168th Street (32).

# PAROXYSMAL COLD HEMOGLOBINURIA ASSOCIATED WITH DEMENTIA PARALYTICA

## Report of Treatment with Penicillin

FENWICK T. NICHOLS Jr., M.D.
and
CAROLINE J. WILLIAMS, M.D.
Atlanta, Ga.

Paroxysmal cold hemoglobinuria is a syndrome characterized by the intravascular hemolysis of red blood cells and the excretion of hemoglobin in the urine following exposure to cold. It is one of the rarer complications of late syphilis. Less than 300 cases were found in the literature[1] up to 1932, and since that time only 40 additional cases have been reported.[2] In most instances this condition occurs in patients with latent syphilis, either congenital or acquired.

In this syndrome the intravascular hemolytic reaction is dependent on the presence in the serum or plasma of a hemolysin, which is absorbed by the red blood cells only at low temperatures. Complement is not necessary for this phase but is essential for hemo-

lysis to occur when the body is rewarmed (the Donath-Landsteiner reaction). The serum of patients with paroxysmal cold hemoglobinuria will hemolyze the red blood cells of other persons in the same blood group, but the erythrocytes of patients with this condition are not lysed by the serum of normal persons. This hemolysin is distinct from the Wassermann reacting substance (that is, reagin), and there is no correlation between the titer of the complement fixation or flocculation tests for syphilis and that of the hemolysin, except that both usually decrease following antisyphilitic therapy.

Evidence that this disease is caused by syphilis seems well established, but the mechanism remains obscure. The coexistence of active clinical syphilis and paroxysmal cold hemoglobinuria are uncommon. The finding of the Donath-Landsteiner hemolysin in patients with late syphilis has varied from less than 0.2 per cent to 20 per cent.[3] In a study by Donath and Landsteiner of 93 patients with dementia paralytica, only 1 patient was found to have paroxysmal cold hemoglobinuria but 6 others had a positive Donath-Landsteiner reaction without clinical manifestations of hemoglobinuria.[4]

The following case seems worthy of reporting because of the rather unusual association of dementia paralytica and paroxysmal cold hemoglobinuria. This is the third reported case of paroxysmal cold hemoglobinuria treated with penicillin.

## REPORT OF CASE

*History.*—J. T. E., a white mechanic aged 48, was admitted to Grady Memorial Hospital Oct. 22, 1948 for treatment of early dementia paralytica. At the age of 32 the patient had a penile lesion which was diagnosed as syphilis by his family physician, who treated him with seven or eight injections of an arsenical preparation. There was no subsequent treatment or serologic test for syphilis until the present admission. Approximately seven years before admission the patient noted the onset of severe shaking chills after exposure to cold. This was followed by fever, sweats, nausea, dizziness and the passage of dark urine. The patient attributed these symptoms to an old back injury. He also experienced blanching and numbness of his fingertips and ears but noted no evidence of urticaria. These attacks occurred every winter and were so severe that the patient was often too weak to work. Following these episodes, jaundice of several days' duration was frequently noted. The patient soon learned that he could not go outside in cold weather, sit in a draft, bathe in cool water or otherwise be exposed to cold without precipitating these symptoms. His last attack was in the winter of 1947-1948. He had had no attacks during the cold months preceding this hospitalization, because he feared to venture outside and had remained in the house during cold weather.

Approximately five months prior to admission the family of the patient noted that he had become nervous, weak and forgetful. These symptoms progressively increased before admission, and he was observed to have extreme emotional lability and an undue concern over trivialities. He experienced episodes of confusion and on several occasions awoke at night and was disoriented for a short period of time. The patient himself demonstrated signs of anxiety and felt that something was wrong, but he was unable to describe the cause of this fear. There was no history of headaches, paralyses or convulsions. The remainder of his past history was unremarkable. The wife of the patient denied having had syphilis, and her serologic test for the disease was negative.

*Physical Examination.*—On physical examination the blood pressure was 150 mm. of mercury systolic and 80 mm. diastolic; the temperature was 99 F., the pulse rate 110 and the respiratory rate 24. The patient was a well developed and moderately obese white man. He appeared to be neatly dressed but was extremely anxious, grunting and moving his hands and feet restlessly. The pupils were small but equal and reacted sluggishly to both light and accommodation. The ocular fundi appeared normal. Ears, nose and throat were normal. There was no enlargement of the superficial lymph nodes. The size of the heart appeared to be within normal limits, and there were no murmurs. The lungs were clear to percussion and auscultation. The abdomen was obese, and no organs or masses were palpable. The genitalia were normal. The reflexes were hypoactive but equal bilaterally. Pain, touch, position and vibratory sensations were normal. There were slight, continuous tremors of the hands, lips and tongue.

A mental status examination showed the patient to be slightly depressed, and quite concerned about his illness, without delusions or hallucinations. The patient was oriented as to place but confused as to the day of the week, the month and the year. There was some impairment of his objective memory for both recent and past events. His fund of knowledge was somewhat limited. He was able to repeat four digits, though slowly. Only the simplest type of calculation was possible. There was some slurring of the test phrases and his handwriting was tremulous.

*Laboratory Data.*—Laboratory examination on admission revealed 3,900,000 red blood cells per cubic millimeter, a hemoglobin level of 11 Gm. per hundred cubic centimeters, and a white blood cell count of 5,800 per cubic millimeter with a normal differential. His blood was type A, Rh positive. The sedimentation rate (Westergren) was 30 mm. in sixty minutes; the nonprotein nitrogen 47 mg., total serum protein 6.7 Gm., cholesterol 188 mg. and the serum bilirubin 0.2 mg., per hundred cubic centimeters. Urinalysis was normal. The urinary urobilinogen was within normal limits. Reaction to the serologic test for syphilis was positive with 10 Kahn units. Tests for cold agglutinins were negative. Examination of the spinal fluid revealed normal pressure and dynamics, 62 lymphocytes per cubic millimeter, 1 plus Pandy reaction, protein 56 mg. per hundred cubic centimeters, a 4 plus reaction to the Wassermann test with 0.0312 cc. of spinal fluid, and a mastic reaction of 443211. The red blood cells did not exhibit increased fragility. Ehrlich's test and a Mackenzie "rough" test (which is described later) were both positive. Since the patient showed hemoglobinemia with Ehrlich's test, a Rosenbach test was not considered advisable. Tests were not made for the presence of dermolysins. The Donath-Landsteiner test was positive with a 1:2.5 dilution of serum. An electrocardiogram and teleoroentgenogram of the chest were interpreted as normal.

*Treatment and Course.*—The patient was treated with 60,000 units of penicillin G in aqueous solution every three hours, intramuscularly, for a total of 4.8 million units. He exhibited a mild Herxheimer reaction in the first twenty-four hours after the onset of treatment, with a rise of temperature to 101.2 F. but without aggravation of clinical symptoms. The patient's hospital course was otherwise uneventful, and some clinical improvement was noted at the time of discharge from the hospital on Nov. 9, 1948.

Following hospitalization, the patient has been observed at monthly intervals up to the present. One month after discharge from the hospital he was cheerful and better oriented; he showed some return in memory and in his ability to perform simple arithmetical calculations. The patient had not had chills or episodes of hemoglobinuria, though he had been out in freezing weather on several occasions. Six months after treatment, the patient's mental status appeared to be entirely normal. His wife believed that he had become completely well. A spinal fluid examination revealed 3 lymphocytes per cubic millimeter, 32 mg. protein per hundred cubic centimeters, a positive Kolmer reaction with 0.1 cc. of fluid and a normal mastic test.

There had been no further manifestations of hemoglobinuria. Ehrlich's test was still positive six months following discharge from the hospital, but there was no clinical reaction following a Rosenbach test. The Donath-Landsteiner test had not significantly changed since his admission, being positive in a 1:1 dilution of serum. Definite hemolysis was still present with this concentration of serum, but the reaction required lower temperatures (4 to 10 C.). On admission of the patient the Donath-Landsteiner test had been positive at temperatures of 18 to 20 C.

### COMMENT

This patient showed almost complete recovery from symptoms of paroxysmal cold hemoglobinuria and dementia paralytica within a short time following treatment with penicillin. The symptoms of hemoglobinuria had been present for seven years and were rather incapacitating, while mental changes had been noted for only about five months before treatment.

The clinical manifestations of paroxysmal cold hemoglobinuria vary in intensity but follow the same general pattern. Following exposure to cold, the patient soon experiences prodromal symptoms of malaise, muscular aches and pains, abdominal cramps, headaches, nausea and vomiting. Certain patients manifest vasomotor disturbances such as urticaria, fluctuating blood pressure or Raynaud's phenomenon. Shortly after exposure to cold, the patient experiences a shaking chill, the severity of which is dependent on the degree of hemolysis. The patient's temperature may rise to 102 or 104 F. If large numbers of red cells are hemolyzed the patient may be definitely jaundiced for several days. Attacks may leave the patient with weakness, lassitude and mild nausea. The liver and spleen are occasionally palpable during the attack.

One to four hours after chilling, the urine becomes dark red, wine or mahogany in color. It frequently contains albumin, casts and even a few red blood cells. Spectroscopic examination reveals the color to be due to oxyhemoglobin, methemoglobin and sometimes hematin. The red blood cell count and hemoglobin content may drop decidedly following an attack. An initial neutropenia occurs during the exposure to cold, followed by a leukocytosis in the chill phase. The blood serum is colored pink or red, and in severe cases the serum bilirubin level may be elevated. The serologic test for syphilis is almost always positive. If the patient has persistently negative tests for syphilis the diagnosis of paroxysmal cold hemoglobinuria should be questioned.

The majority of patients with paroxysmal cold hemoglobinuria usually manifest a positive response to Ehrlich's test. This test consists of binding the finger with a ligature and immersing it in ice water for a few minutes. After the finger is warmed, local hemoglobinemia can be demonstrated. This reaction is less hazardous than the Rosenbach test and is preferable in the investigation of patients with hemoglobinuria. The Rosenbach test consists of immersing the hands or feet in ice water for ten to twenty minutes. The resulting hemolysis may produce severe constitutional symptoms and has occasionally resulted in anuria. Repetition of the cold water test may cause sufficient depletion of the patient's complement that negative reactions are obtained.

The Mackenzie "rough" test consists of chilling a sample of the patient's blood in ice water. A positive test is denoted by hemolysis after the blood is rewarmed. In the Donath-Landsteiner test a mixture of the patient's red cells, varying dilutions of his serum and guinea pig complement is immersed in ice water and then rewarmed. Hemolysis of the patient's cells is noted in a positive test. Appropriate controls are necessary for the interpretation of both these tests.

Differentiation from other common types of hemoglobinuria is usually relatively simple. In the Marchiafava-Micheli syndrome the hemoglobinuria occurs only at night. March hemoglobinuria occurs only after considerable physical exertion, such as after forced marches by soldiers. The Donath-Landsteiner reaction is negative in both these conditions. Paroxysmal cold hemoglobinuria must also be differentiated from that caused by cold hemagglutinins. In this condition hemolysis occurs while the blood is immersed in the ice water, and rewarming is not necessary for hemolysis to occur. Stat's work indicates that a very high cold agglutinin titer of approximately 1:3,000 is necessary for this reaction.[5]

It has been noted that only a few patients with paroxysmal cold hemoglobinuria have clinical manifestations of syphilis. Of the 40 patients reported since 1932, only 1 had a manifest lesion (interstitial keratitis) at the same time as the hemoglobinuria. Following inadequate antisyphilitic therapy, several patients have shown improvement in their symptoms of hemoglobinuria but have later exhibited signs of neurosyphilis.[6]

Routine antisyphilitic treatment of patients with paroxysmal cold hemoglobinuria is usually efficacious in producing a clinical cure or in ameliorating the severity of the reaction. Only 2 cases have been reported treated with penicillin. One patient had a decrease in symptoms and a persistently positive Rosenbach test two months following treatment with 3.6 million units of penicillin.[7] The other patient had a clinical cure after receiving 5 million units of penicillin but continued to have moderate reactions to the cold water test six months after treatment.[2a]

Penicillin has also been administered to a patient with Raynaud's syndrome and syphilis who had a positive Donath-Landsteiner test but did not exhibit hemoglobinuria.[8] There was no clinical improvement two months after treatment.

Our patient has shown complete clinical recovery following administration of 4.8 million units of penicillin.

### SUMMARY

A patient with early dementia paralytica associated with paroxysmal cold hemoglobinuria is reported. Treatment with penicillin has produced good clinical results.

# MASS PENICILLIN PROPHYLAXIS

## An Experiment with Negative Results

CLIFFORD KUH, M.D., Dr. P.H.
and
MORRIS F. COLLEN, M.D.
Oakland, Calif.

The great incidence of respiratory disease and the resultant loss of time from work or regular activities have led many investigators to seek a means to prevent this type of morbidity. We were first struck by the favorable reports of the prophylactic use of the sulfonamide drugs in both the army and the navy during

The penicillin used in this study was supplied by Lederle Laboratories Division of American Cyanamid Company.

Abraham Gans, Ph.B., helped to code and tabulate data on International Business Machine cards; Martha Eaton, A.B., Sc.M., assisted in the interpretation of statistical data.

the war,[1] even though later articles rather coolly emphasized the development of sulfonamide resistance by bacterial organisms.[2]

Through serving medically the members of a voluntary health insurance plan, we would have had the opportunity to try these drugs on a large civilian population and would have yielded to the temptation to do so, were it not for the reports of toxicity,[1a] and even of agranulocytosis and death,[1b] despite the administration of small daily doses. With the advent of penicillin there came the universal recognition of its relative harmlessness, and accordingly an important barrier was removed from initiation of a large scale prophylactic experiment on a civilian population.

Reports of the preventive value of penicillin, notably against rheumatic fever in children, have been favorable, though the groups of subjects were small. Lapin[3] reported on the oral administration of 50,000 units of penicillin twice a day to children aged 8 months to 10 years. He noted a 75 per cent decrease in febrile days in the group of 148 children receiving penicillin compared to their experience in the preceding year, and a 70 per cent decrease in febrile days compared to the results among 110 other children who served as controls. The control group received nothing, not even a placebo.

Maliner and Amsterdam[4] reported no recrudescences of rheumatic fever among 22 children with a rheumatic history on administration of penicillin troches three times a day during those months when upper respiratory infections were most prevalent, whereas there were 4 definite recurrences of rheumatic fever in the same number of controls. Burke[6] observed favorable results from penicillin prophylaxis in a study that included both children and adults.

As with the sulfonamide compounds, the question of bacterial resistance to penicillin has been raised. The subject has been discussed by Lapin[3] as well as Milzer and others.[7] Milzer believed that such resistance could be overcome by increasing the size of the prophylactic dose. Lapin found no evidence that resistance developed. Florey[8] has said, "Fortunately it appears to be much more difficult to acquire resistance to penicillin in vivo than in vitro . . ." It was hoped to investigate this aspect of the subject.

## METHOD OF STUDY

It was proposed to place a minimum of 1,000 persons on a regimen of orally administered penicillin and another control group of 1,000 on a placebo, daily for a period of a year. The intended dose of a 50,000 unit tablet of penicillin twice a day throughout that period of time for 1,000 persons implied the use of 730,000 tablets and an equal number of placebos. At prevailing minimum rates the penicillin alone would cost over $100,000. Nevertheless, the proposal was presented to Dr. Benjamin Carey of the Lederle Laboratory Division of the American Cyanamid Company, who promptly responded favorably.

Accordingly, a letter asking for volunteers was sent in August, September and October, 1947, to over fifteen thousand heads of families and individual subscribers representing upward of sixty thousand members of the Permanente Health Plan. The letter emphasized the importance of the proposed research and stated frankly that some who accepted the invitation would receive penicillin and others would receive something else "for comparative purposes." The study was limited to family members above 7 years of age.

The letter explained that a month's supply, or sixty tablets, would be given at one time and that those participating in the study would be expected to report to the hospital pharmacy once a month for a new supply. In addition, the participants would be asked to fill out a form at the start of the study and each month thereafter, answering a number of questions about their health. To increase the validity of reports the forms were printed questionnaires containing squares either to be checked for yes or no replies or to have numerical answers inserted. All information thus obtained was to be coded and punched on statistical cards. The research was to be essentially a large scale statistical study.

No attempt was to be made to distinguish between virus and bacterial infections. While the penicillin was not expected to prevent virus infections or the common cold, it seemed that the drug might prevent bacterial complications or sequelae. The letter to subscribers covered this point.

Exactly 2,937 persons accepted the invitation, and all were started on the study; 1,486 in the experimental group and 1,451 controls. Although the response was larger than anticipated, it was expected that a number would drop out, how many no one could predict. As a matter of fact, when the last tablets were dispensed on July 26, 1948, eleven months after the first tablets left the pharmacy window, there were only 631 persons still actively participating in the study; 295 in the experimental group and 336 controls. The falling off of subjects became fairly gradual and uniform until the last few months, when a more rapid decline set in. As the study progressed the smaller number of participants enabled us to increase the size of the dose of penicillin without necessitating the acquisition of more material.

The study produced 9,264 monthly reports. In other words, the records represented 9,264 patient months. The dispensing of penicillin versus placebo was determined at random; those health plan members whose record file number was an odd number received penicillin; those with an even number, the placebo. However, all the members of a family received the same tablets as the head of the family. This resulted in almost perfect penicillin-placebo distribution, 4,582 being in the experimental group and 4,682 being controls.

For best utilization of the penicillin, the subject was requested to take the first dose one-half hour before breakfast and the second dose one-half hour before the evening meal.[3] These and other instructions were carefully printed on the bottle label.

The original form filled out by the volunteer requested such pertinent information as sex, age, race, occupation, previous history in respect to respiratory disease, experience in the past year in regard to number of respiratory infections or time lost from daily routine and past use of tobacco, vitamins, medicine and penicillin.

The monthly report form, which was completed when the month's supply of tablets was replenished, ascertained the subject's respiratory experience in the preceding month in respect to the incidence of infection in himself or members of his family, time lost from work or from regular activities, necessity of visiting a physician and number of days spent in a hospital, if any. Although we were primarily interested in respiratory disease, we also included a number of inquiries on nonrespiratory illness, which followed the general tenor of the foregoing questions.

One inquiry on the monthly report asked the number of tablets which the subject had neglected to take because of memory failure, inconvenience or other reason. If this number were large in the experimental group it might explain a negative result. However, the data thus obtained revealed that not over 4.4 per cent of the penicillin tablets were missed during the course of the study. It is unlikely that this small amount would have affected the outcome of the experiment.

RESULTS

The major results of the study were essentially negative in respect to both respiratory and nonrespiratory illness. In fact, it is striking how similar are the statistics for the penicillin and placebo groups. This has seemed so evident that as far as many of the data are concerned elaborate statistical analysis hardly appeared indicated. Yet, despite the negative results, the work revealed a number of interesting sidelights.

The first trial run of the punch cards was made after the study was in effect approximately four months. Since it was noted that there was no appreciable difference between experimental and control groups, it was decided to double the dose; each volunteer was therefore asked to take two of the 50,000 unit tablets twice a day. After the double dose had been maintained for three months the results again proved to be negative. The dose was then quadrupled, giving each subject 400,000 units of penicillin daily. Again after four months the results were still negative. The number of patient months on single, double and quadrupled doses was fairly well distributed; namely, 3,582, 3,685 and 1,997 (or 38.7 per cent, 39.8 per cent and 21.5 per cent of the total), respectively. The results are shown in table 1.

The data in this table will be reviewed briefly. In a comparison of experimental and control groups, actual figures would have little meaning unless related to the number of persons in each group. This relationship is expressed as a ratio and calculated in percentage. In the table the percentages which favor, however slightly, the users of penicillin are in bold face type, as are the corresponding figures from which the percentages are derived.

In the left half of the table there is an isolated instance of a statistically significant difference favoring the experimental group. This occurs in respect to the time lost from work or activity due to respiratory illness when the subjects were on the double dose. The number of days lost and corresponding percentages are 969, or 53.6 per cent, for the penicillin group and 1,184, or 63.2 per cent, for the control group. However, the preceding columns reveal that the number of persons involved was 229 for the penicillin group and 243 for the placebo group; the respective percentages being 12.7 and 12.9, or essentially the same figure. So the difference in days lost cannot be explained on the basis of the number of persons. As a matter of fact, it can be shown that the difference in lost time was actually due to more serious and protracted illness among a few persons in the control group, a possibly fortuitous circumstance.

To the right of the table the users of penicillin on single and quadruple doses are favored in respect to the number of days lost from work or activity and in respect to the number of days hospitalized (nonrespiratory cause), but those on double dose are not so favored. Since there is no logical reason why single and quadruple doses should have an effect which could not be obtained by a double or intermediate dose, the results must be considered fortuitous.

Repeated analyses have been made of the statistical cards, separating out those who reported for the preceding twelve months a varying incidence of respiratory infection or varying days of time lost from respiratory cause. Again results were negative. The statistical cards have been studied in respect to use of tobacco, to mention another breakdown, and nothing significant was found.

* The percentage expresses the ratio that the preceding figure bears to the total number of reporting subjects in the corresponding group (column at extreme left). Percentages favoring the penicillin group are in bold face type; percentages favoring the control group, in light face. The percentage figure and the figure preceding it are set in the same type.

In view of previous reports of successful prophylaxis in children, the records were studied by sex and age in decades. The observations are reported in table 2. Only a few scattered figures favoring the penicillin group are statistically significant, but there is no consistent, statistically significant advantage for the penicillin users of either sex in any age group.

## TOXICITY

We were impressed by the relatively large number of mildly or moderately severe toxic reactions to oral penicillin. There were no disastrous effects, however. Only 1 patient required brief hospitalization for a dermatitis.

The large number of reactions is in contrast to the experience of Lapin, who reported mild toxicity in only 3 of 148 children. According to most writers, the percentage of toxic reactions to oral penicillin is small and the reactions are mild. In this study the single dose screened out almost all the sensitive subjects, so that doubling or quadrupling the dose produced practically no additional toxic reactions other than mild digestive upset in which the quantity of tablets probably played a part. But the strange thing is that those receiving the placebo, a tablet of calcium carbonate of equal size, reported almost as much discomfort as did those receiving the penicillin.

Of course, in a study of this sort where subjects could drop out at will, there was no way of knowing the exact percentage of toxic reactions. In order to approximate the figure, self-addressed, prepaid postcards were sent to 1,500 of those who discontinued (750 on penicillin and an equal number on placebos). From these, 627 replies were received; 322 from experimental subjects and 305 from controls. The replies are analyzed in table 3.

It will be noted that 90 of those who received penicillin reported that "the tablets did not agree with them," most of the subjects indicating digestive or cutaneous disorders, or headaches. Sixty-four persons who received the calcium carbonate placebo signified similar subjective or objective complaints.

As to the percentage of reactions among the experimental subjects, it can be said that there was considerably upward of 6.1 per cent (90 of 1,486 persons receiving penicillin). The postcards reached only about

* The percentage expresses the ratio that the preceding figure bears to the total number of reporting subjects in the corresponding group (column at extreme left). Percentages favoring the penicillin group are in bold face type; percentages favoring the control group, in light face. The percentage figure and the figure preceding it are set in the same type.

† Including nonidentified

five-eighths of the penicillin-taking subjects who dropped out; assuming that there was the same proportion of reactions in those who were not polled, the figure would be increased to 9.7 per cent, yet this figure takes no account of additional persons with untoward reactions who did not reply to the postal inquiry.

There were reasons other than unpleasant reactions which caused persons to drop out, such as the inconvenience of getting to the hospital (142 on penicillin, 123 on placebo). Sixty on penicillin and 83 on the placebo said they ceased to cooperate in the study because they experienced no benefit. Only 6 on the placebo admitted frankly that they discontinued because they suspected that they were getting the placebo.

Eight discontinued the penicillin and 4 the placebo because they had read that they might acquire resistance to penicillin. Other reasons included pregnancy and difficulty in swallowing the tablets. One man quit because he was gaining weight, the calcium carbonate of the placebo evidently helping his peptic ulcer.

## COMMENTS

While many mildly disagreeable reactions to the tablets were thus recorded, it is interesting to note that many glowing reports of subjective benefits were reported, despite the negative results of the study. And there were almost as many enthusiasts in the control group as in the experimental group. This seems to substantiate the well known fact that persons may at times react favorably to a situation in which they are merely shown attention; for example, the kind of special attention that made them a part of a seemingly important mass penicillin experiment.

Subjects still come to the hospital requesting an opportunity to purchase penicillin for prophylactic use, but the effort is made to discourage them on the basis of actual results of the study and the cost of the antibiotic. Likewise, some of these demands for continued medication come from those who received the placebo. Thus, this study emphasizes the value of having a large number of subjects on a controlled program before arriving at favorable conclusions, and this is particularly true where reliance would have to be made on subjective improvement alone.

While it was not the intention of the study to make chemical or bacterial analyses, blood levels of penicillin were taken in 6 subjects who ingested two tablets about a half hour before breakfast. These levels, taken an hour after the meal, varied from 0.15 to 0.31 units, which are considered to be effective doses.[3]

It would have been interesting to determine whether the taking of penicillin tablets possibly prevented a gonococcic infection. No one taking either penicillin tablets or placebos reported to the hospital or clinic with such an infection. A patient on penicillin was hospitalized with a tubo-ovarian abscess, but the organism was Escherichia coli. This fact is interesting because, as far as is known, the organism is not affected by penicillin. In this case smears and cultures revealed no gonococci. During the course of the study 22 cases of gonorrhea were observed among health plan members not on the study, but obviously no conclusion can be drawn from this limited observation.

Finally, because of the references in the literature to acquired resistance to penicillin, already commented on, a review was made of the hospital records of all persons on the study who required hospitalization at the Permanente Hospitals and who received therapeutic doses of penicillin for their primary illness or for associated infection such as a complicating pneumonia. There were 8 patients in this group. Two of them, 1 with bronchogenic carcinoma and the other with phosphorus poisoning, died from the primary illness. Of the remaining 6 patients, 2 subjects had been on the study eight months (1 had asthmatic bronchitis and the other, the tubo-ovarian abscess previously mentioned); 1 subject had taken the penicillin tablets for seven months (another case of asthmatic bronchitis); 1 for six months (a case of secondarily infected second and third degree burns); 1 for five months (an incomplete abortion) and 1 for one month (a nonspecific prostatitis). Except for the E. coli in the case of tubo-ovarian abscess, the infecting organism was not identified. In no case, however, was there any evidence that the penicillin was less effective because of its previous prophylactic administration.

## SUMMARY

In conclusion, this study of mass penicillin prophylaxis, which involved 4,582 patient months in the experimental group and 4,682 patient months in the control group, discloses practically no difference for respiratory and nonrespiratory illness in respect to incidence of sickness, days lost from work or regular activities, days of hospitalization or number of persons who sought medical consultations. Respiratory infection in other members of the family was not affected.

There were many relatively mild reactions both to penicillin and to the placebo, besides many reports of subjective improvement experienced by both experimental and control subjects despite the negative results.

There was no evidence that subsequent therapeutic administration of penicillin was hampered by the previous taking of prophylactic doses.

# VALIDITY OF PNEUMOENCEPHALOGRAPHIC DIAGNOSIS

## A Study of Five Hundred Pneumoencephalograms in Children

LOUIS CASAMAJOR, M.D.
ROBERT W. LAIDLAW, M.D.
and
PHILIP J. KOZINN, M.D.
New York

When Dandy[1] thirty years ago introduced the procedure of pneumoencephalography he offered neurologists a simple nonoperative method of visualizing certain of the structures of the brain during life. Gradually enthusiasm increased for the new method. Pancoast and Fay[2] believed that encephalography is indicated in any condition of the brain which might impair the cerebrospinal pathways. Davidoff and Dyke[3] stated: "Excluding individuals with increased intracranial pressure we believe that all patients with organic disease of the brain upon whom a diagnosis cannot definitely be made, whether it be with regard to the nature or location of the disease, should be subjected to encephalography." Pendergrass[4] expressed a similar opinion.

Just as slowly the enthusiasm waned, and neurologists began to doubt that the procedure was necessary in most cases. Thus Adson[5] questioned the value of frequent and promiscuous use of pneumoencephalography and doubted whether sufficient additional information was obtained in many cases to compensate the patient for the suffering he must endure.

In searching for an answer to the question we have reviewed 500 pneumoencephalographs of patients on our service and offer the following material.

### THE MATERIAL

*The Epilepsies.*—There were approximately 250 encephalographic studies performed on children with the clinical diagnosis of the convulsive state. In 55 per cent of these cases the encephalogram was interpreted as pathologic by the roentgenologist. However, in the great majority of these cases (49 per cent) the pathologic entity reported was bilateral or unilateral "cerebral atrophy or hypoplasia." (This diagnosis will be discussed later.) In only 6 per cent of the convulsive cases (in which suspicion of no other clinical entity such as neoplasm was seriously entertained) were more specific pathologic conditions found, such as porencephaly, agenesis of the corpus callosum, tuberous sclerosis, neoplasm, and internal hydrocephaly secondary to subdural hematoma.

In 8 per cent of the jacksonian type of convulsions pathologic lesions were reported on the encephalogram —and these pathologic entities were all "cerebral hypoplasia."

The clinical diagnosis and the treatment was unchanged by the encephalographic observations in 88 per cent of the patients with epilepsy. In 6 per cent of these persons with convulsive states, in whom the possibility of a brain tumor or subdural . had was entertained, the diagnosis was clarified ker, elimination of these possibilities. In another 6 pre the diagnoses were changed from the convulsive t to some of the diagnoses previously listed.

*Brain Tumors.*—A ventriculogram rather than encephalogram was made in the majority of childre who were suspected of cerebral tumor. Therefore the analysis of the following 29 cases does not represent the total material on the child neurology wards.

In 10 cases a tumor was visualized in the encephalogram in the area predetermined clinically. In 3 cases the localization of the tumor was changed from intraventricular neoplasm to craniopharyngioma, from intracranial neoplasm to optic chiasma glioma, from left frontal neoplasm to right frontal neoplasm.

The diagnoses were clarified and changed in 11 brain tumor suspects from internal hydrocephalus to craniopharyngioma in 1 case and to intraventricular cyst in another, from cerebellar neoplasm to cerebellar sclerosis, from subdural hematoma to idiopathic grand mal and cerebral hypoplasia and from brain tumor suspect to post-traumatic encephalopathy.

In 4 cases the encephalogram was misleading. It did not reveal a papilloma of the choroid plexus of the fourth ventricle in 1 case or papilloma of the choroid plexus of the left lateral ventricle in another case. These were discovered at operation in the former instance and at autopsy in the latter. In a third case a tumor of the brain stem was not visualized by the encephalogram. In a fourth case the encephalogram disclosed normal conditions in 1935 but, when repeated in 1939, revealed a tumor of the left temporal lobe.

The encephalogram is of great value in those suspected of having tumor of the brain. It usually verifies, localizes or rules out neoplasms. However, in 21 per cent of our cases in which a definite neoplasm existed the encephalogram did not reveal the tumor. A normal encephalogram does not rule out neoplasm.

*Post-Traumatic Syndrome.*—There were 35 encephalographic studies of children with clinical evidence of post-traumatic syndrome. In 55 per cent of these the encephalogram was interpreted as revealing pathologic conditions. However, "cerebral hypoplasia" was the condition most commonly found. Porencephaly was occasionally noted. On the whole the encephalogram was not revealing, although it did tend to rule out subdural hematoma.

*Postinfectious Group.*—Encephalograms were made on 40 children with the clinical diagnosis of postinfectious syndrome. Cerebral hypoplasia was reported in 50 per cent of the encephalograms, and other conditions such as toxoplasmic encephalitis, porencephaly and aplasia of the corpus callosum were reported in another 10 per cent of the cases. The encephalogram was not particularly helpful as a diagnostic aid in the postinfectious group.

*Congenital Anomalies and Miscellaneous Lesions.*—There were approximately 150 cases of congenital anomalies and miscellaneous lesions. In 65 per cent of these cases pathologic findings were reported by the roentgenologist. Although about 59 per cent of the cases displayed only cerebral hypoplasia, many interesting lesions were uncovered by the encephalogram in the other 6 per cent. The clinical diagnosis of hydrocephalus was changed in 1 case to agenesis of the corpus callosum and in a second to cerebral atrophy. Pro-

s of cerebral and cerebellar atrophy, ydrocephalus and various structural visualized.

*ciency.*—The material was analyzed to correlation between the pneumoenceph- agnosis (particularly cerebral hypoplasia ) and the intelligence quotient. There were atients with a pneumoencephalographic diagnosis cerebral hypoplasia whose intelligence quotient varied from 20 to 149. Ten of these patients had an intelligence quotient over 80 and only 12 had an intelligence quotient below 50.

Table 1 shows the degree of correlation between the intelligence quotient and the pneumoencephalographic diagnosis of cerebral hypoplasia or atrophy.

It is interesting to note that in 22 of 34 severely defective children (intelligence quotient below 50), the encephalogram showed no evidence of cerebral hypoplasia or atrophy. However, hypoplasia was discovered more frequently in the severely defective children than in those with normal intelligence.

TABLE 1.—*Pneumoencephalographic Diagnosis*

| I. Q. | No. of Patients | Normal | Atrophy or Hypoplasia |
|---|---|---|---|
| Above 95 | 89 | 83 | 6 |
| 90 to 95 | 20 | 18 | 2 |
| 80 to 90 | 22 | 20 | 2 |
| 70 to 80 | 26 | 18 | 8 |
| 50 to 70 | 30 | 27 | 3 |
| 25 to 50 | 28 | 18 | 10 |
| Below 25 | 6 | 4 | 2 |

TABLE 2.—*Information Obtained from Encephalograms*

| Clinical Diagnosis | Number of Cases | Normal % | Abnormal,* % | Abnormal Other Than Cerebral Hypoplasia or Asymmetric Ventricles, % of Total |
|---|---|---|---|---|
| Convulsive state | 250 | .. | .. | .. |
| *Generalized* | ... | 45 | 55 | .. |
| Jacksonian | ... | 92 | 8 | None |
| Brain tumors | 29 | 33 | 67 | 52 |
| *Post-traumatic syndrome* | 35 | 45 | 55 | 5 |
| Postinfectious states | 40 | 40 | 60 | 10 |
| Congenital anomalies | 150 | 35 | 65 | 6 |
| Mental Retardation | | | | |
| Miscellaneous | | | | |

* The abnormal includes reports of cerebral hypoplasia.

The diagnosis of cerebral hypoplasia by the roentgenologist does not mean an impaired intelligence; nor does a completely normal encephalogram mean normal intelligence.

## COMMENT

Pneumoencephalography is a method of neurosurgical not neurologic diagnosis. If any therapeutic indications are revealed by it they are of necessity neurosurgical. Pneumoencephalography shows only (1) size, shape and position of ventricles; (2) size and shape of the basal cisterns, and (3) in some cases the pattern of the cerebral convolutions and sulci. The primary and enforcing indications are (*a*) signs of increased intracranial pressure without localizing signs—although in many of these cases ventriculography is the method of choice—and (*b*) increasing focal cerebral signs in the absence of increased intracranial pressure. In the epilepsies we believe that at least two of the following conditions should be present to justify pneumoencephalography: first, that the convulsions are always or predominantly one-sided and occur always on the same side; second, that there are positive neurologic signs on the side of the convulsions; third, that the electroencephalogram discloses abnormal signs only or predominantly on the side opposite the convulsions and the physical signs, and fourth, that the convulsions and other signs are increasing in frequency or severity, or both. Casamajor and others[6] compared the results of the foregoing three methods of clinical investigation in focal convulsive seizures in children and found that the clinical and electroencephalographic data bore closer relationship to each other and to the locality of the convulsions than did those from pneumoencephalography. The latter gave little help either for diagnosis or treatment in most cases.

We have cast doubt on the validity of the diagnosis of cerebral atrophy or hypoplasia from pneumoencephalographic films. Davidoff and Dyke[2] in their book "The Normal Encephalogram" admit that in all the cases which they reported there was ample evidence that suspicion as to the normality of the brains was justified. However, they checked their results with postmortem examinations, standard textbooks of anatomy and the study of 4,000 pneumoencephalograms. All this in their opinion gave them "a fairly accurate idea of the normal appearance of the structures." Their criteria of cerebral atrophy or hypoplasia were not any too definite. They judged atrophy or hypoplasia from the widening of the cerebral sulci and enlargement of the ventricles, although they gave no accurate measurements. Later these authors[7] supplied some more accurate figures as to the size of the normal ventricles, giving what they consider the normal limits of size. Apparently these measurements were taken on adult brains. Hence, it would be difficult to postulate the normal in children of different ages.

The pneumoencephalographic observations in mental deficiency are of especial interest. The data seem to prove conclusively that there is no correlation between the structure of the brain and intelligence in the vast majority of cases. There would appear to be no reason for pneumoencephalography in persons who are mentally defective unless there is definite evidence of a focal cerebral lesion. It is of little practical importance to know what sort of a brain, as shown by pneumoencephalography, a mentally defective person has; that is the brain with which he must go through life, and gas studies will not alter the prognosis or treatment in the slightest.

## CONCLUSIONS

1. Pneumoencephalography is a method of neurosurgical not neurologic diagnosis.

2. Pneumoencephalography is a necessary diagnostic technic when tumors of the brain are suspected.

3. Pneumoencephalography has little to offer in clarifying the diagnosis or indicating the treatment in most cases of epilepsy or the convulsive state.

4. There is no indication for pneumoencephalography in persons who are mentally defective unless there are also signs of growing focal lesions of the brain.

# Clinical Notes, Suggestions and New Instruments

## SERUM HEPATITIS IN A BLOOD BANK WORKER

SIDNEY LEIBOWITZ, M.D.
LOUIS GREENWALD, M.D.
IRA COHEN, M.D.
and
JOSEPH LITWINS, M.D.
New York

Numerous clinical and experimental studies within the past six years have demonstrated that virus hepatitis, including both the infectious and the homologous serum type, is transmissible to human beings by the parenteral injection of human serum. Apparently the only clinical differentiating characteristic of these two virus infections, when both are thus transmitted, is the shorter (twenty to forty days) incubation period in the case of the former and the longer (forty to one hundred and sixty days) incubation period in the latter. Neefe[1] has proposed the terminology "virus hepatitis I.H." and "virus hepatitis S.H." to differentiate the naturally occurring disease from the artificially transmitted homologous serum type.

Most commonly reported has been the accidental transmission of virus hepatitis by means of transfusions of whole blood, plasma and convalescent serum and injections of vaccines to which human serum has been added.[2] Less commonly encountered have been accidental transmission by use of unsterile syringes or needles, as in penicillin therapy[3] or in arsenical antisyphilitic therapy[4] or even during ordinary venipuncture for withdrawal of blood; the latter hazard was reported by Mendelssohn and Witts[5]; who noted that blood regurgitates back into a vein when the tourniquet is released. Finally, the use of the "multiple dose per syringe" technic for injections into large groups of persons has been a source for transmission of the virus, even when a sterile needle is used for each injection.[6] The probable mode for contaminating the material in the syringe, in this instance, is the aspiration of tiny amounts of infective serum (from the infected patient source) while testing to determine that the needle is not in a vein. Havens[7] has shown that parenteral inoculation of as little as 0.01 cc. of acute phase serum from a patient with infectious hepatitis is sufficient to cause the disease in a human volunteer.

In all these accidental transmissions of virus hepatitis the danger has been to the patient; i. e., to the recipient of the injection. The case herein presented is noteworthy because it strongly suggests a similar danger to the technician who performs the venipuncture or the injection.

### REPORT OF A CASE

*History.*—M. L., a 41 year old woman, was admitted to Beth Israel Hospital on Sept. 23, 1948, with jaundice of twenty-four hours' duration. She was a nurse who for the previous ten months had been employed in the blood bank of a large hospital in New York City. In her duties at the blood bank, she withdrew the needle from the donor's arm and the receiving bottle after the phlebotomy was completed. On many occasions she had pricked her hands and fingers with the needles. Four weeks before admission to the hospital she noticed a lack of energy and fatigue on arising in the morning. For three weeks she noticed the presence of a headache. Anorexia had been present for two weeks. She was a light cigaret smoker, using about 4 packages weekly; about two weeks before admission, she experienced an abrupt distaste for smoking. At that time her stools became clay colored and her urine dark red. Her urinary output diminished, as judged by decreased volume as well as decreased frequency. During these two weeks before her admission pain developed in the epigastrium, with eructations and nausea, and she vomited on one occasion. In the week prior to admission the upper part of her abdomen felt distended, as though her "skirt were too tight," and she lost 4 to 6 pounds (2 to 3 Kg.) in weight. She had no chills, but had a fever during this week, her temperature reaching 102 F. forty-eight hours before admission. On the day before admission she consulted a physician, who observed jaundice and an enlarged liver. Examination of the chemical content of the blood, performed the day prior to admission, revealed: normal total proteins, serum bilirubin 1.8 mg. per hundred cubic centimeters, cephalin flocculation 4 plus at 24 hours, thymol turbidity 23 units, alkaline phosphatase 6.6 units and prothrombin time 19 seconds (control, 14 seconds).

Her past history was noncontributory. She had never been previously jaundiced. She had had no blood or plasma transfusions. She had one child, aged 12. Nobody in the immediate family had been ill in recent months.

*Physical Examination.*—On admission her temperature was 98.6 F., pulse rate 80 per minute and respirations 20 per minute. Her blood pressure was 128 systolic and 82 diastolic. Her scleras were icteric. Her fauces was injected. There were no enlarged or tender lymph nodes. The heart and lungs were normal. The liver was enlarged 3 fingerbreadths below the costal margin, extending to the level of the umbilicus. It was smooth and tender to fist percussion, the tenderness being elicited immediately on contact with the fist. The spleen was not palpated. There was right costovertebral tenderness but no shoulder tenderness on palpation.

*Laboratory Data.*—Results of all pertinent blood cell counts, urine analyses and examinations of the chemical content of the blood are recorded in table 1. Roentgenographic examination of the abdomen on the eighth hospital day showed no evidence of gallstones or other abnormalities.

*Diagnosis.*—The admission diagnosis was virus hepatitis. Without a known incubation period, and in the absence of human transmission experiments, it was impossible to decide whether the I.H. virus or S.H. virus was involved. However, in view of the history of frequent needle pricking of the hands and fingers during the course of work in a blood bank and failure to elicit any other likely source of infection, it was felt that the virus hepatitis here was serum transmitted.

*Course.*—The patient was placed on a regimen of complete bed rest. Her diet was high in calories with moderately low amounts of fat, and she received supplementary B complex vitamins by mouth and vitamin K parenterally. Accessory lipotropic amino acids were not administered. Liver extract was not administered.

Her temperature rose to 100 F. on the second hospital day and thereafter remained normal. On the fourth hospital day a tender enlarged right posterior auricular lymph node was noted. Liver tenderness was no longer elicited by the fifth hospital day, and the liver had receded by then to 2 fingerbreadths below the costal margin. The patient noted increased urinary output at the beginning of the second week. Coincident with this, her appetite returned to normal and she had nearer normal general strength and sense of well-being. At the end of the second week, she was no longer jaundiced clinically and her serum bilirubin value fell to 0.83 mg. per hundred cubic centimeters (by method of Malloy and Evelyn, normal values 0.1 to 0.25 mg.) Her liver at this stage, still nontender, was palpable 1½ fingerbreadths below the costal margin. She was allowed out of bed at the end of four weeks and experienced no abdominal pains or other untoward symptoms. Her liver did not enlarge any further or become tender on this out of bed activity. Jaundice did not return. She was discharged on October 25, thirty-three days after admission. At the time of discharge results of the thymol

turbidity and cephalin flocculation tests were still abnormal, the result of the former, however, showing a diminution from a maximum of 37 to 13.5 units. The bilirubin was 0.21 mg. per hundred cubic centimeters. Her liver was nontender and palpable about 2 fingerbreadths below the costal margin.

Two months after discharge the patient was clinically well. Her appetite was good, and her taste for cigarets had returned. She tended to tire more readily than prior to her illness. Her liver was not tender, but still extended 2 fingerbreadths below the costal margin. The thymol turbidity was 5.8 units, the result of the cephalin flocculation test was 3 plus at 48 hours and the serum bilirubin 0.52 mg. per hundred cubic centimeters.

punctures, finger puncture or any type of needling of human beings to protect himself against accidental pricking, even when sterile instruments are assuredly employed.

The case introduces a new type of occupational hazard which merits compensation. The New York State Workmen's Compensation Board, after formal hearing of this case on Jan. 21, 1949, decided that it was the result of an accident and that a causal relationship had been established between the illness and the conditions of employment and made an award in favor of the patient. This represents, to our knowledge, the first such instance of the granting of a compensation award for a virus hepatitis infection.

## COMMENT

The history of multiple needle pricks on hand and fingers sustained by this patient in the course of her duties at the blood bank persuades us to conclude that this was the mode of her infection. Admittedly, we cannot be absolutely certain that she had not contracted sporadic infectious hepatitis by other than parenteral means, but we think that this is unlikely in view of the highly suggestive history. However, we make no attempt to define the virus type involved as of the I.H. or S.H. variety, since we are in no position to decide the absolute incubation period and since both the virus types may be transmitted parenterally.[8]

The hazard which this case illustrates has wide applicability. It points to the obvious necessity for caution on the part of a physician or technician who engages in phlebotomies, veni-

This case provided us with the opportunity to study the sheep cell agglutination reactions in virus hepatitis, as part of a larger study stimulated by the clinical and hematologic similarities between virus hepatitis and infectious mononucleosis. The method employed for the test follows that of Davidsohn,[9] with final volumes totaling 0.35 cc., the tubes standing at room temperature for two hours and read immediately thereafter and titers expressed as dilutions prior to the addition of the 2 per cent sheep cell suspension. The results, including absorption studies with boiled guinea pig kidney, boiled ox erythrocytes and human liver, are detailed in table 2. The human liver antigen absorption study was prompted by the recent report by Eaton, Murphy and Hanford[10] of consistent absorptions with this antigen in acute hepatitis. Our results do indicate an elevated presumptive titer (1:320) early in the illness and a prompt fall to 1:80 within the next week. The absorption with boiled guinea pig kidney was complete at all stages of the illness, and the boiled ox erythrocytes consistently showed incomplete absorptions. Therefore, the heterogenetic antibody acted here like the normal Forssman antigen and could be differentiated from that characterizing infectious mononucleosis. The human liver tests, employing both boiled and unboiled liver antigen, reflected little or no absorption of the antibody.

## SUMMARY

A case of serum-transmitted virus hepatitis in a 41 year old woman blood bank worker is reported. The mode of transmission was probably the accidental pricking of her hands and fingers during the withdrawal of needles from donors' arms and from receiving bottles after phlebotomies were completed. The hazard to other than the recipient of human blood products is emphasized. The physician and technician are cautioned against accidental self inoculation with the hepatitis virus by pricking of the skin while performing phlebotomies, venipunctures or injections in human beings. This case represents the first known instance in which a compensation award was granted for a virus hepatitis and introduces a new type of compensable occupational hazard. A heterogenetic antibody with the absorption characteristics of a Forssman antibody is identified in the serum of this patient.

---

# RADIODERMATITIS OF THE LIP AFTER EXPOSURE TO ARC WELDING

SIDNEY VERNON, M.D.
New Brunswick, N. J.

Control of the hazards of industry is the constant concern of the industrial surgeon. The early diagnosis of chronic lesions of the lip also commands attention, because cancer of the lip is frequently observed. In the 2 cases herein described there is a similar history of exposure to arc welding with the resultant formation of typical lesions of the lip. Since this condition has not been reported and has been an industrial hazard, it seems appropriate to record these cases.

## REPORT OF CASES

Case 1.—D. J. E., a sergeant aged 31, entered Fort Monmouth Station Hospital on May 18, 1948, because of a lesion of the lower lip on the left side. The condition had been noted by two medical officers, who advised biopsy.

The patient had noted a "scab" on the left side of his lower lip since November 1945. A crust about 3 mm. in diameter would form; this became hard and leathery on the third day and "looked dirty." The center then became depressed, with the edges frayed and projecting; at this time it would catch and bleed. By the end of the day it would fall off, leaving a hollow place surrounded with a white ring. Then the crust would commence to reform, and the cycle would be completed again by the fifth day. In the beginning the patient thought that the condition was a cold sore or came from a "bad stomach." Later he became concerned about the lesion.

It was noted that he had worked from September 1941 to March 1945 in shipyard construction as a shipfitter. His duties were to read blueprints while working among arc welders who were assembling ballast tanks. The welders protected their eyes and face by wearing hoods; this patient's protection consisted only of goggles for his eyes.

Past history related an operation for hernia in 1938 and an attack of urinary calculi in 1944. It was also noted that this patient had occasional dyspepsia. In the past, while a civilian, the patient had smoked as much as two and one-half packs of cigarets a day.

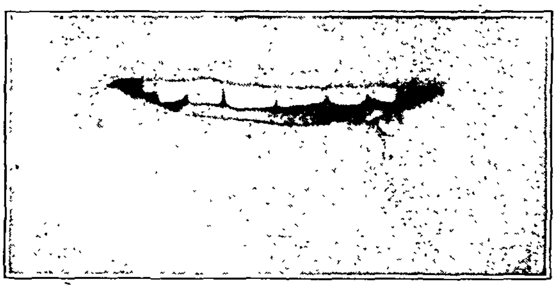

Fig. 1 (case 1).—Fissured, thickened lower lip three weeks after excision of the lesion.

Examination revealed an adult who looked older than his stated age of 31. His complexion was ruddy, his lower lip displaying a lesion about 1 cm. from the commissure and about 3 mm. in diameter. The lesion was square, grayish brown and thicker than the rest of the lip. The entire lip seemed pallid and thickened, with distinct sharp creases in the membrane which ran radially from the vermilion border inward. Nutritional lesion and leukoplakia were considered. While the troublesome crust seemed benign, it was considered necessary to perform a biopsy in order to settle the diagnosis.

With the patient under local anesthesia a triangle of the lip was excised which removed the lesion. The wound was sewed up in three layers, mucous membrane, muscle and skin. The wound healed well without incident, and all sutures were removed by the fifth day. The patient made an uneventful recovery.

The pathologist reported that the epidermis showed thinning of the prickle cell layer, absence of rete pegs and slight hyperkeratosis. Below the epidermis the upper corium revealed basophilic degeneration of connective tissue and destruction of elastic fibers. Foci of lymphocytes were found throughout the corium. Small dilated capillaries were increased in number. The epithelium of the mucous membrane revealed marked hyperkeratosis. There were areas of parakeratosis. The granular cell layer was thickened. There was moderate acanthosis, but the rete pegs were flattened so that they lay in a flattened plexiform arrangement. Numerous small capillaries and vascular spaces which were present gave the area a telangiectoid appearance. Surplus epithelium, elastosis, basophilic degeneration of connective tissue and telangiectasia gave this lesion the appearance of radiodermatitis. The arc welders' light was considered a source of energy sufficient to have caused this lesion.

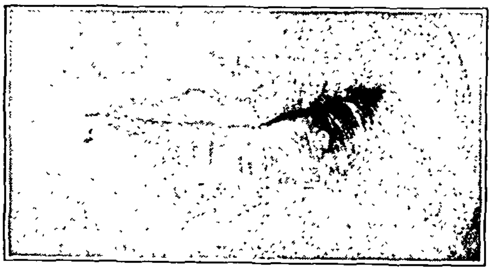

Fig. 2 (case 2).—Lesion and fissured lip before excision.

Case 2.—B. L. M., a private aged 25, was admitted to the hospital on Aug. 17, 1948, complaining of an annoying lesion on the left side of his lower lip. There was no pain, itching or burning, but constant irritation caused him to bite his lip. About six weeks before admission he had come to the surgical clinic complaining of the crust. The lesion was electrodesiccated, which gave him relief for a time after it healed. However, the condition recurred and he entered the hospital for excision of the lesion.

This patient had worked in his father's welding shop from the time he was 12 until he was 22 years of age. He was a part time helper and was "in and out of the shop all the time." There was a history of venereal warts for "the past two years." He had also been "bothered lately by plantar warts." He smoked one and one-half packages of cigarets a day and occasionally had shortness of breath; there was no history of heart trouble.

In 1934 a "wartlike growth" appeared near the right side of the lower lip and grew to the size of a match head, forming a crust in the course of two months. This lesion had been excised; it healed leaving a tiny scar.

On examination the lip was thickened, the vermilion border indistinct and the mucous membrane pallid. There were many vertical creases, especially near the corners and more pronounced on the felt. An irregular grayish yellow crust 4 mm. in diameter lay 1 cm. from the lateral commissure.

On August 18 the lesion was excised with the patient under local anesthesia; the wound was repaired in three layers. Healing occurred without event; sutures were removed by the fifth day.

The pathologist reported "radiodermatitis, a lesion that could have been caused by radiation exposure to roentgen ray, ultraviolet rays, excessive sunlight or arc welding."

### COMMENT

These cases are reported because they show the effect of an industrial hazard on the lip to cause a typical lesion, possibly precancerous. The lesion in both cases was on the lower lip.

## CUTANEOUS BURNS DUE TO FLUORESCENT LIGHT

R. RALPH BRESLER, M.D.[*]
Philadelphia

Fluorescent lighting has hitherto been considered entirely harmless. In December 1948 an informal request was submitted to the Medical Department of a large pharmaceutical manufacturing organization to investigate complaints of a mild type of cutaneous irritation occurring among the 5 female operators in the penicillin filling-room. These complaints were minor, for at no time had any of the affected employees reported to the plant dispensary for treatment, nor had any time been lost from work as a result of this condition.

Chief complaints of the operators were redness, dryness and occasional itching of the skin, most prominent on the forearms, arms and exposed areas of the neck and upper sternal region. Examination revealed erythematous areas, with dryness and some evidence of moderate desquamation. Lines of demarcation on the upper part of the arm at the edge of the sleeve were noted in 1 case.

Questioning revealed that these lesions were transient and that they disappeared over a week end or when the operator worked in a different area for a day or two. It was also stated that the lesions occurred only in this particular room and that when the affected operators worked on the same products in other locations, symptoms did not result. For the latter reason, contact dermatitis due to a particular drug sensitivity was immediately eliminated as a direct causative factor.

### POSSIBLE CAUSATIVE FACTORS

The room where the exposure occurred was then carefully inspected. It is an enclosed room, measuring 12 by 14 feet (366 by 427 cm.), air conditioned in a closed system and lighted by recessed, shielded, fluorescent ceiling fixtures. In the room are two filling tables, each partially hooded by plexiglass sections. Inside of each hood is an ultraviolet sterile-lamp with shield and, suspended from the under side of the cabinet top, a fluorescent light for illumination. There is a shielded ultraviolet sterile-lamp over the door and another above the window on the wall opposite the door.

*Ultraviolet Burn.*—Having eliminated a drug sensitivity reaction as a causative factor, the next most likely possibility appeared to be ultraviolet burn. According to the standard operating procedures in that department, the ultraviolet sterile-lamps were used only when no operators were in the room, such as during rest periods, lunch period and at night. The supervisor gave assurances to the effect that this procedure was being followed to the letter by the operating personnel. This was confirmed by repeated spot checks at irregular intervals. Since the ultraviolet lamps were not in use during times of occupancy, it was obvious that they could not directly be causing these lesions.

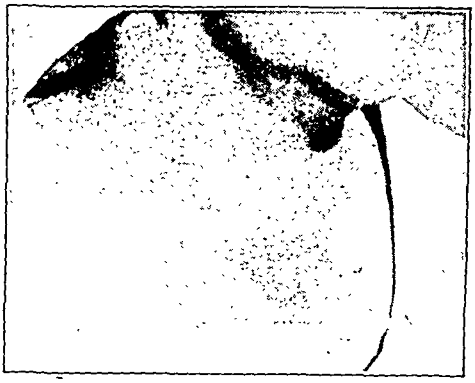

Fig. 1.—Erythematous area with sharp lines of demarcation at the neckline.

As a further check, however, the Safety Department was requested to measure the intensity of the ultraviolet radiation with all the lamps in operation. Readings taken at each work place indicated that the shields afforded the operators effective protection against ultraviolet radiation from the sterile-lamps.

*Ozone Sensitivity.*—Consideration was then given to the possibility of a dermatitis from ozone sensitivity. The type of ultraviolet lamp in use in this room created a not inconsiderable quantity of ozone, easily discernible by odor on entering the room. It was considered entirely possible that ozone was present at times in sufficient concentration to cause cutaneous sensitivity reactions.

Ozone itself is toxic when inhaled in sufficient amounts. For this reason, as well as for its possible role as a skin sensitizer, it was considered desirable to obtain readings of its concentration in the atmosphere of the room under actual working conditons.

The services of the Pennsylvania Bureau of Industrial Hygiene were requested for this study. Determinations were made of ozone concentrations under varying conditions of use of the ultraviolet lamps. Even after the lamps were permitted to operate all night and continuously during the test, the ozone concentration in the room never exceeded the accepted maximum allowable concentration (one part per million parts of air for an eight hour working day). In view of the findings, the field engineer of the bureau did not consider an ozone inhalation hazard to exist and consequently made no recommendations.

In cases of sensitivity dermatitis, however, even relatively minute quantities of a sensitizing agent may cause reactions. In an attempt to eliminate ozone as a causative factor, all ultraviolet equipment in the room was disconnected entirely for a period of two weeks. The cutaneous reactions continued in spite of this.

As a remotely possible source of ozone, the air-conditioning equipment was carefully inspected to discover the existence of any minor short circuit that might have created an arc, with the formation of ozone. No such arc was found, and the equipment was declared in excellent operating condition. Ozone, then, was eliminated as a source of the dermatitis.

---

[*] Chairman, Industrial Health Section, Philadelphia County Medical Society.

No definite causative factors having as yet been determined, the filling room was again carefully examined, and an item by item comparison made with the other filling rooms in which cases of dermatitis had not occurred. The only significant mechanical difference in the rooms was the illumination of the hooded area of the filling tables by fluorescent tubes, as compared with ordinary incandescent lighting of the filling tables in the other rooms.

At the same time, a second examination of the affected workers toward the end of a day spent entirely in the penicillin filling room revealed bright erythematous areas on the exposed surfaces of the skin, with sharp lines of demarcation at the clothing edges. The affected areas presented a typical clinical picture of ordinary sunburn. The photograph of one of the affected operators (fig. 1) demonstrates such an area at the neckline. In order that comparison may be made with the worker's normal skin, the uniform at the neckline has been loosened and lowered somewhat from its normal position. Figure 2 also shows the V-shaped erythematous area at the neckline, as well as a roughened, finely desquamating area on the lateral surface of the arm and the dorsal surface of the forearm.

Although I had never seen or heard of cutaneous burns from ordinary fluorescent tubes, the physical and clinical evidence pointed directly to such a condition. At a working distance of only 10 to 14 inches (25 to 35 cm.), it seemed entirely logical that small amounts of ultraviolet radiation from such a tube could be causing burns, provided that the exposure was sufficiently prolonged.

*Output in Watts for a 40 Watt (3,500° Kelvin Color Temperature) White Fluorescent Tube*

| Output | Range | Description |
|---|---|---|
| ... | Below 2,800 A | Ultraviolet |
| 0.01 | 2,800 to 3,200 A | Ultraviolet |
| 0.1 " | 3,200 to 3,800 A | Ultraviolet |
| 1.6 | 3,800 to 5,000 A | Visible light |
| 3.4 | 5,000 to 6,000 A | Visible light |
| 3.0 | 6,000 to 7,600 A | Visible light |
| ... | Above 7,600 A | Infra-red |

Each of the two cabinets in question contained one 20 watt, white fluorescent tube, uncovered except for a narrow metal glare-shield. This tube was in operation all during the production day, so that there was a possible worker-exposure of six to eight hours a day.

A request was forwarded to the manufacturer of the tube for performance specifications and spectral ranges emitted. From the information received, the following picture was constructed.

The shortest wavelength transmitted by a fluorescent tube is 2,800 angstrom units. Wavelengths shorter than this are absorbed by the glass of the tube. The output in watts through the spectral range is shown in the accompanying table.

This particular problem involves the 2,800 to 3,200 angstrom range—the so-called "tanning" or "burning" range. Since the tube in use was a 20-watt tube, there would appear to be an ultraviolet emission of 0.005 watts in the burning range. While admittedly minute in quantity, this amount of ultraviolet radiation at a working distance of only 10 to 14 inches (25 to 35 cm.) might, over a period of six to eight hours, produce a cutaneous condition of the type illustrated.

### REVIEW OF THE LITERATURE

Search of the literature revealed only 1 pertinent report. James[1] listed 2 cases of dermatitis resulting from exposure to fluorescent light while at work. He described a female employee who exhibited a dermatitis about her face and eyelids, first noticed immediately after the installation of a single 40 watt daylight fluorescent tube 3 feet (91.4 cm.) above her desk. With the lamp turned off and without medical treatment, her skin returned to normal in two weeks. After three more weeks without symptoms, she worked under the light again for half a day and experienced a severe recurrence of her dermatitis. This employee was a brunette, who claimed to tolerate sunlight well.

In the second case also, a woman presented a dermatitis involving the back of her neck and her face, particularly the eyelids. Fluorescent lamps had been installed in her office just prior to the start of the symptoms. The installation was multiple in nature, consisting of four 40 watt daylight tubes placed at a distance of about 8 feet (244 cm.) from the worker's back. Although she was soon transferred to another office, she was still exposed to this radiation for ten to thirty minutes each day while consulting her files, and the dermatitis continued. Routine patch tests, including those for cosmetics, gave negative results. The patient stated that her skin itched and burned for hours after each exposure to the fluorescent light. She was instructed to apply a tannic acid solution to the affected areas of the skin several times a day and to wear tinted polaroid glasses. Under this regimen, her cutaneous condition cleared up rapidly. Whenever she failed to apply the solution or to wear her glasses, the dermatitis reappeared. This patient was a blonde with fine, delicate skin. She stated that she normally avoided sunlight in the summer because her skin would not tolerate it.

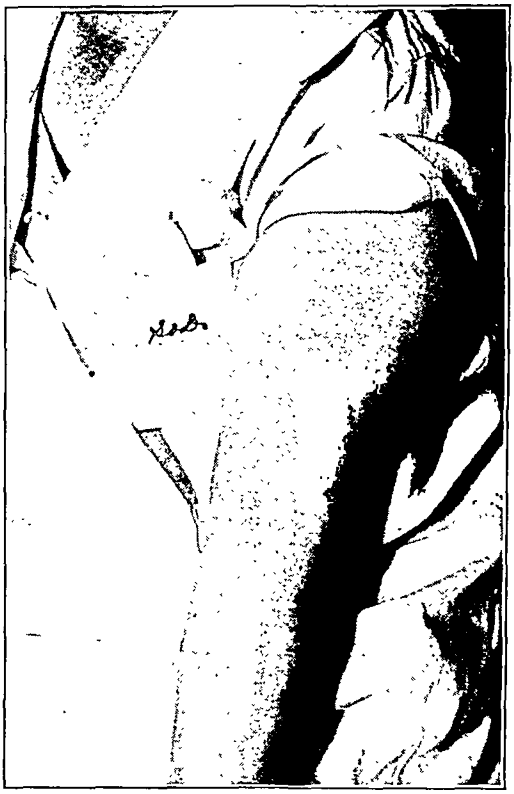

Fig. 2.—Roughened, finely desquamating area on the lateral surface of the arm and the dorsal surface of the forearm; V-shaped erythematous area at the neckline.

The 2 patients of James seem to exhibit a genuine hypersensitivity to one or more of the bands of light emitted from fluorescent tubes. The greater working distances involved, plus the short periods of exposure, would appear to rule out the direct burning action of minute quantities of ultraviolet radiation, such as exists in these burns acquired in the filling room. No other reports could be found in the literature on the occurrence of dermatitis or other dermatologic effects as a result of exposure to fluorescent light.

---

[1] James, A. P. R.: Sensitivity of the Skin to Fluorescent Light, Arch. Dermat. & Syph. 44: 256 (Aug.) 1941.

### REMEDIAL MEASURES

With temporary acceptance of the premise that these filling-room operators were suffering from mild ultraviolet burns from fluorescent light, three remedial procedures appeared feasible:

1. To replace the fluorescent fixture with regular incandescent lighting. This was considered undesirable because of the quantity and quality of light required for proper performance of the work, because of the higher amount of heat produced by the incandescent bulbs and for maintenance reasons.

2. To have the affected operators use protective solutions, ointments or creams. This was considered undesirable because of possible contamination of the products being handled. In addition, use of such protective preparations requires interruption of work, is inconvenient for the operator and is difficult to enforce.

3. To guard the offending tube with an all-round plate-glass shield. This would absorb the offending ultraviolet radiation without decreasing the quantity of the illumination or materially altering its quality. In addition, it had the added benefits of requiring no effort on the part of the employee, and of not affecting in any way the products being handled.

Since the third method was obviously the most desirable, a ¼ inch (0.64 cm.) thick all-round plate-glass shield was constructed and installed about the offending tube in one of the two filling tables.

### RESULTS

In two days, the operators at the table with the shielded tube were free of any cutaneous reaction, while the operators at the other table continued to display the same erythematous condition. When the operators exchanged tables, the first group, now at the unprotected table, rapidly exhibited the erythema again, while in the second group the condition just as quickly cleared up.

A similar plate-glass shield was constructed for the fluorescent tube in the other table, and the erythema among these operators disappeared entirely. The condition has not recurred.

### COMMENT

These cases are of particular interest to physicians, since they point out a previously unrecognized hazard from fluorescent lighting. With the increasing use of fluorescent lighting, it is only logical to expect an increase in the number of persons who may react unfavorably to it.

Physicians should keep in mind the possibility that undesirable cutaneous reactions may follow prolonged exposure to fluorescent lighting at relatively short working distances.

1401 Magee Avenue (11).

---

**Si Monumentum Requiris, Circumspice.**—Let us recall that Sir Christopher Wren, to whom London owes St. Paul's Cathedral, The Middle Temple Gateway, and many celebrated churches now destroyed by bombs, was an LL.D. of Oxford, who studied and practiced medicine in the City of London. It is recorded that when studying medicine at Oxford he was the first to advocate intravenous injections and watch the effect of injected wine and beer into the veins of dogs, and later he experimented with opium and other drugs on human beings. Wonderful plates illustrating the anatomy of the brain are memorials of his scientific attainments which eventually gave way to architecture. It is a matter of pride to remember that Wren at the height of his celebrity as an architect stayed in London along with Samuel Pepys (when most of their colleagues had fled) while the Great Plague raged, the one reverting to his original profession, the other thinking only of his beloved Navy and the thereatened Dutch Invasion. In Christopher Wren surely the Debt of the Fine Arts to Medicine is well exemplified. So let us remember the epitaph on his tomb in St. Paul's: "Si Monumentum Requiris, Circumspice."—V. B. Green-Armytage, M.D., The Debt of the Fine Arts to Medicine, *Cambridge University Medical Society Magazine*, Easter term, 1949, Reprinted from "The Embryo," Summer, 1947.

# Council on Pharmacy and Chemistry

## REPORT TO THE COUNCIL

*The Council has authorized publication of the following report from the Therapeutic Trials Committee, a standing committee of the Council on Pharmacy and Chemistry.*

AUSTIN SMITH, M.D., *Secretary*.

## EFFECTIVENESS OF CHLORESIUM IN WOUND HEALING AND DEODORANT EFFECTS

N. HENRY MOSS, M.D.
BURTON A. MORROW, M.D.
RICHARD C. LONG, M.D.
*and*
I. S. RAVDIN, M.D.
*Philadelphia*

Of the various considerations in the management of wounds, those in which clinicians are generally interested are the rate of healing and the odor and appearance of the wound. Many attempts have been made in past decades to introduce new therapeutic agents which would improve the progress of one or all of these qualities. Yet, the multitude of preparations alone suggests that not one of them has been uniformly successful.[1]

Recently, the water-soluble derivatives of chlorophyll have received enthusiastic support for their beneficial effects on various types of wounds. The clinical reports concerning chlorophyll therapy were impressive enough to stimulate our interest in following its effect on the course of various types of wounds at the Hospital of the University of Pennsylvania. For many years the Surgical Clinic and the Harrison Department of Surgical Research have been interested in the healing process. Thus, it was hoped, in spite of past unsuccessful attempts by many investigators, that perhaps an agent at last had been found which would uniformly promote wound healing.

This communication is a report of the use of chorophyll therapy in the management of wounds. It encompasses a study of 36 patients in whom special attention was given to the rate of wound healing and to wound odor and appearance. Forty-two cases were originally included in the project, but 6 of these cases have been discarded from the present series because of either the patients' failure to return or the intervention of other therapeutic measures which invalidated the results.

### RATE OF WOUND HEALING

Since no substance has been found to date uniformly to promote and accelerate wound healing and in view of other convincing experimental evidence, most investigators believe that strict adherence to sound surgical principles is more important than the application of any substance in the process of wound healing and that the use of various agents prepared for the local treatment of wounds should not be considered a substitute for good wound care.[2] Emphasis has thus been placed on the importance of asepsis, the gentle handling

---

*Several tables and illustrations have been omitted to conserve space; these will be included in the reprints.*

From the Harrison Department of Surgical Research Schools of Medicine, University of Pennsylvania and the Surgical Clinic of the Hospital of the University of Pennsylvania, Philadelphia.

The investigation was conducted under the auspices of The Therapeutic Trials Committee of The Council on Pharmacy and Chemistry pursuant to a contract between The Rystan Co., Inc., and The University of Pennsylvania.

of tissue, excision of all devitalized tissue and the preservation of the local blood supply. Not only rigorous care of the local wound, but also consideration of the general condition of the patient has been repeatedly stressed by numerous authors.[3]

Several publications in the last few years have reported that chlorophyll derivatives possess tissue-stimulating properties.[4] Smith and Livingston,[4a] in a series of 1,372 experimental lesions produced in animals and treated with chlorophyll, showed healing time to be decreased by approximately 25 per cent in over two thirds of the animals. These results, together with other clinical reports concerning chlorophyll therapy,[5] have prompted the present study of testing objectively its effect on the healing rate of wounds in man.

## METHOD

It was realized from the very first that the evaluation of a new agent of this type is a difficult task. Variables introduced by numerous extraneous local and general factors may readily mislead the investigator to unjustifiable conclusions. Furthermore, one must avoid the use of clinical impressions of the encouraging response of the wound to the application of the local agent. To use such clinical impressions, even though compared with the effects of other materials used alternately or after a previous period of resistance to healing, is to introduce errors that readily invalidate the results of the study. It is evident then, as Smelo [1a] pointed out over a decade ago, that reliable assessment of the so-called wound stimulant requires more accurate methods of evaluation than those generally employed. The problem demands a quantitative approach.

Such a quantitative method was provided by the studies of Carrel and Hartman,[6] who demonstrated that superficial wound repair in man occurs according to a regular geometric curve which may be expressed by a mathematic equation in function of area and time. Du Noüy's [7] formula of these relationships permits the prediction of the period in which a wound should normally heal and the calculation of the expected area of the wound at any time during the course of repair. By determining the normal rate of healing one is thus more qualified to take into consideration the variables that may speed or retard tissue repair.

The method of Smelo [1a] was utilized to determine the precise measurements of the surface area of the wound each time it was dressed. The area was obtained by placing a transparent celluloid film directly on the wound and tracing the line of union between the epithelial edge and the granulating surface. This tracing was then transferred to a sheet of paper and the area determined with a planimeter.

Cultures were taken at frequent intervals to follow the effect of the chloresium preparations on the bacteriologic makeup of the wounds. Quantitative dilution methods were not employed, in view of the convincing work of Anderson,[8] who showed that decreased bacterial counts do not in themselves tend to promote wound healing.

The investigation on healing was carried out on 25 patients, all in good general health unless otherwise stated. The wounds differed in size and etiologic aspects. Every effort was made to determine the presence of any factor remote from the site of the wound which may have unduly influenced the local changes in healing. In the series of patients treated, 11 had infected wounds, 3 had surgically clean wounds, 3 had burns, 6 had lesions resulting from venous stasis and 2 had ulcers due to sickle cell anemia.

Chloresium ointment in moderately generous quantities was applied to a square gauze dressing, which was placed over the wound and held there with simple bandaging. Dressings were changed every other day. When necessary, local débridement of devitalized tissue was performed. Nineteen of the 25 patients were treated as outpatients. The remainder were ward patients with ambulatory privileges for all but 2 patients.

## RESULTS

In this investigational study, the terms "accelerated," "normal" and "retarded" with respect to healing time have the following definitions: Accelerated means the time of healing was faster, normal means the time was equal, and retarded means that the time was slower than was theoretically expected by du Noüy's formula.

The series of patients is divided into two groups on the basis of whether complete healing was achieved during the course of therapy. Of the 25 patients, 18 in the first group were still receiving chlorophyll therapy when the project was stopped for evaluation (table 1). In the second group are the 6 patients who achieved complete healing of their wounds prior to cessation of the study (table 2). In addition, 1 other patient experienced a sensitivity skin reaction to the chloresium ointment, and therapy was discontinued before adequate data were available. Analysis of the results in the first group reveals that 14 patients had retarded healing, 2 normal healing and 2 accelerated healing. These results were classified on the basis of a comparison between the actual measured surface area and the theoretically expected surface area after the respective days of healing as calculated by du Noüy's [7] formula. A deviation of plus or minus 10 per cent from the calculated area was considered within the range of normal healing. Of the 2 patients whose wound showed accelerated healing, 1 had a wound following a recurrent abscess of the thigh and the other had a burn.

TABLE 5.—*Interpretation of Quantitative Results*

| Term Used | 4+ | 3+ | 2+ | 1+ |
|---|---|---|---|---|
| Excellent | 0 | ... | ... | ... |
| Very effective | 1+ | 0 | ... | ... |
| Satisfactory | 2+ | 1+ | 0 | ... |
| Equivocal | 3+ | 2+ | 1+ | 0 |
| No benefit | 4+ | 3+ | 2+ | 1+ |

The results of wound healing in patients of the second group were determined by a comparison of the actual time with the theoretically expected time required for complete wound healing. Of the 6 patients in this group, 1 had retarded healing, 2 had normal healing and 3 had accelerated healing. Likewise in this group a deviation of plus or minus 10 per cent was considered within the normal range. The instances of accelerated healing in this group occurred in 1 patient with an ulcer resulting from a furuncle, in another with an ulcer due to venous stasis and in the third with a lesion resulting from a burn.

[7] DuNoüy, P. L.: J. Exper. Med. **24:** 461, 1916.

[8] Anderson, D. P.: Ann. Surg. **108:** 918, 1938.

Untoward reactions to chloresium consisted primarily of slight itching, which was noted in 6 patients. In 1 of 2 other patients in whom vesicular eruptions occurred with use of chloresium, 1 patient was known to have a definite allergic background. Treatment should be discontinued if redness or itching appear during treatment.

In 3 out of 10 instances the chloresium ointment may have had bacteriostatic activity. The organisms affected included hemolytic Staphylococcus aureus, alpha and beta streptococci and an unidentified gram-negative rod.

## COMMENTS

In an attempt to quantitate the effect of chlorophyll therapy on wound healing, it is believed that a more accurate means of evaluation has been used than in previous reports. In the series herein reported ideal quantitative evaluation was not possible because of the limitations of the du Noüy formula. Yet, what has been completed with the use of this formula is considered a more accurate evaluation than clinical observations even with attempted controls. The phenomenon of wound healing is notable for its complexity and inherent variables, and clinical observations do not usually consider the differential effect of these variables on the healing process. The advantage of one's using the du Noüy formula lies in the recognition of two of the most significant of these variables, the age of the patient and the size of the wound. Other variables known to influence the process of wound healing,[2b] but not expressed in the du Noüy formula, include the following, which may be grouped under two headings: (1) general status of the patient—hypoproteinemia, vitamin deficiency (A, C or K), electrolyte and water balance, anemia or systemic infection—and (2) local factors—tissue trauma, presence of devitalized tissue at the wound site, local temperature and integrity of the blood supply.

* Index of healing (see table 3).

† A factor obtained from figure 2.

‡ Determined by a comparison of the theoretically expected area to the actual area measured after T days of healing.

§ When the calculated area of the wound is 0.4 sq. cm. or less, the wound is considered to be healed.

‖ Extrapolated values (see figure 1).

It is therefore necessary to establish some quantitative relationship between the rate of wound healing and these other variables even though it is a difficult task. In the evaluation of the results in the present study, the factors listed herein under general conditions of the patient by a careful clinical survey were not considered significant variables in 20 of the 24 patients. Of the 4 patients in whom a general factor was considered significant, 2 patients had sickle cell anemia and 1 patient a positive serologic reaction, and all were found to have retarded healing by our study. The other patient had hypoproteinemia, yet unexpectedly was found to have accelerated wound healing.

Of the local factors listed, variations in temperature of the local part was not thought to be of significance in this group of patients. Tissue trauma, on the other hand, appeared to be an influencing factor in 1 patient with a decubitus ulcer following a burn over the sacrum, but healing time was normal. In regard to presence of devitalized tissue, every attempt was made completely to eliminate it from the wound site, and this was successful in most instances. In 4 patients it is possible that devitalized tissue was not so thoroughly removed as to eliminate its influence on the healing process. Three of these 4 patients had retarded healing; 1 had accelerated healing.

The last of the local factors listed, the integrity of the blood supply, is the major significant variable that was not adequately evaluated by our study and represents an important limitation to the completion of an accurate quantitative evaluation of chlorophyll as a wound stimulant in man. It was hoped that the accumulation of a very large series of control cases would provide corrective factors to the du Noüy formula to overcome this limitation, and such an attempt was made. However, because of the wide range of results obtained, no definite relationship could be established.

With the method used, the variability was too great to lend itself to a quantitative approach.

### ODOR AND APPEARANCE OF THE WOUND

By contrast to the objective approach of the section of rate of wound healing, a study of the effect of chloresium on the odor and general appearance of a wound, by necessity, requires subjective evaluation. It is recognized that there is a wide range of opinion in reference to odor. Yet, the average of a group of opinions, it was decided, should more closely approximate the true effect than any other known method. An arbitrary quantitative estimation of the intensity of odor of the wound was therefore used as a measure of the effect of chlorophyll therapy. This system ranged from 0 for absence of odor to 4 plus for maximum odor. At least three and up to six opinions were obtained from various staff personnel and the average taken as representative of the final evaluation.

In the series of 11 patients studied (table 4), 7 patients had abdominoperineal resections, in 6 of whom chloresium solution was used to irrigate the posterior perineal wound daily after the packing was removed on the eighth day. The other patient, with an abdominoperineal resection of six years' duration, returned for fulguration of a recurrent rectal carcinoma and for a left anterolateral cordotomy for relief of pain. Two patients had a transverse colostomy; 1 patient had a draining abdominal fistula, and 1 patient had an ulcerating bronchogenic carcinoma. There was also daily use of chloresium solution with the change of dressings in these latter cases. Table 5 shows the means by which the quantitative results were interpreted in descriptive terms. Six of the patients acted as their own controls, with the use for varying periods of time of dry dressings, saline irrigations or chloroazodin (azochloramid®). Additional controls were obtained from similar types of wounds in different patients. With respect to the control series as a whole, chlorophyll therapy was shown consistently to decrease the odor of foul-smelling wounds, and it did so, on the average, within twenty-four to forty-eight hours. No untoward reactions were noted in this group of patients.

Of the 7 patients with abdominoperineal resections, chloresium solution was very effective in 5 and satisfactory in the other 2 patients. Of the 2 patients with transverse colostomy, 1 patient received very effective and the other satisfactory benefit. The patient with a draining abdominal fistula had a satisfactory therapeutic result and the patient with the ulcerating bronchogenic carcinoma a very effective decrease in odor with the use of chlorophyll therapy. In 1 patient with an abdominoperineal resection, chloroazodin was almost as effective a deodorant as chloresium but had the disadvantage of causing local irritation.

In reference to wound appearance, it was the almost unanimous opinion of those concerned with the project that the chloresium ointment tended to produce a clean granulating wound. Regardless of the effect on the healing rate, the wounds had a healthy pink appearance and, in general, looked exceptionally good.

### SUMMARY

In a study of the effect of chlorophyll therapy on the rate of wound healing, various types of wounds were closely observed. With reference to the du Noüy formula, chlorophyll therapy was associated with acceleration of healing in 5 out of 24 patients. In 3 of these 5 patients, local or general factors known to impede the healing process were present. The wounds of 4 patients healed in the normal expected time, in 2 of whom healing was influenced by local factors. The remainder, 15 patients, had a rate of healing less than the theoretical by the du Noüy formula; of these, 13 had either local or general factors present.

These results, while not uncontroversial, suggest that chlorophyll therapy is not a consistent promoter in every case of wound healing within the time limits expected under du Noüy's formula. To do so an agent should be able uniformly to reduce the expected time of healing in every case in all types of wounds.

Chlorophyll therapy did not give any evidence of retarding wound healing.

Chlorophyll was found consistently to be an effective deodorant when used on foul-smelling wounds. Untoward effects of chlorophyll occurred in a minimal number of patients and consisted mostly of itching. Chlorophyll therapy did tend to improve the appearance of wounds and give them a healthy granulating appearance.

# NEW AND NONOFFICIAL REMEDIES

*The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.*

Austin Smith, M.D., *Secretary.*

---

**AMOBARBITAL SODIUM** (See New and Nonofficial Remedies 1949, p. 452).

The following dosage form has been accepted:

Eli Lilly and Company, Indianapolis 6

**Amytal Sodium:** 0.75 Gm. ampuls.

U. S. trademark 161,125.

**CONTRACEPTIVE JELLIES AND CREAMS** (See New and Nonofficial Remedies 1949, p. 285).

The following dosage form has been accepted:

Lanteen Medical Laboratories, Inc., Chicago 10

**Lanteen Jelly:** 85.35 Gm. collapsible tubes. A water dispersible jelly having a $p_H$ of 5.2, prepared from the formula:

| | Per Cent |
|---|---|
| Ricinoleic acid | 0.50 |
| Hexylresorcinol | 0.10 |
| Sodium benzoate | 0.20 |
| Chlorothymol | 0.00769 |
| Gum tragacanth | 1.73 |
| Starch | 0.97 |
| Hydrochloric acid | 0.043 |
| Calcium hydroxide | 0.0264 |
| Perfume | 0.0126 |
| Water sufficient to make | 100.00 |

Packaged with applicator or as a refill without applicator.

**Lanteen Applicator:** A transparent plastic tube threaded to screw onto the tubes of Lanteen Jelly to permit filling by compression of the tube.

**DIGITOXIN-U. S. P.** (See New and Nonofficial Remedies 1949, p. 267).

The following dosage forms have been accepted:

Eli Lilly and Company, Indianapolis 6

**Tablets Crystodigin:** 0.05 mg. and 0.15 mg.

The Upjohn Company, Kalamazoo 99, Mich.

**Tablets Digitoxin:** 0.1 mg. and 0.2 mg.

Wyeth, Incorporated, Philadelphia 3

**Tablets Purodigin:** 0.15 mg.

U. S. trademark 411,271.

**ESTROGENIC SUBSTANCES (WATER INSOLUBLE)** (See New and Nonofficial Remedies 1949, p. 367).

The following dosage forms have been accepted:

Bio-Intrasol Laboratories, Inc., Brooklyn 3, N. Y.

**Solution Natrovin in Oil:** 10,000 I. U. per cc. in sesame oil, 1 cc. ampuls and 30 cc. vials. Preserved with chlorobutanol 0.5 per cent.

Kremers-Urban Company, Milwaukee 1

**Solution Estrugenone in Oil:** 5,000 I. U. per cc. in sesame oil, 1 cc. ampuls. Preserved with chlorobutanol 0.5 per cent.

Carroll Dunham Smith Pharmacal Company, New Brunswick, N. J.

**Aqueous Suspension Estrusol:** 50,000 I. U. per cc., 5 cc. and 15 cc. vials. Preserved with chlorobutanol 0.5 per cent.

**FOLIC ACID** (See New and Nonofficial Remedies 1949, p. 559).

The following dosage form has been accepted:

Eaton Laboratories, Inc., Norwich, N. Y.

**Tablets Folic Acid:** 5 mg.

**MANNITOL HEXANITRATE** (See New and Nonofficial Remedies 1949, p. 273).

The following dosage form has been accepted:

Eaton Laboratories, Inc., Norwich, N. Y.

**Tablets Mannitol Hexanitrate:** 30 mg.

**MERCUROPHYLLINE INJECTION-U. S. P.** (See New and Nonofficial Remedies 1949, p. 317).

The following dosage forms have been accepted:

Kremers-Urban Company, Milwaukee 1

**Solution Mercurophylline:** 62 mg. per cc., 5 cc. ampuls. Each 5 cc. contains 80 mg. of mercury as the mercurial salt.

**Solution Mercurophylline with Benzyl Alcohol 2%:** 155 mg. per cc., 2 cc. ampuls. Each 2 cc. contains 80 mg. of mercury as the mercurial salt.

**METHIONINE** (See New and Nonofficial Remedies 1949, p. 415).

The following dosage form has been accepted:

Abbott Laboratories, North Chicago, Ill.

**Tablets Methionine:** 0.5 Gm.

**PENICILLIN** (See New and Nonofficial Remedies 1949, p. 148).

The following dosage forms have been accepted:

Chas. Pfizer & Co., Inc., Brooklyn 6

**Crystalline Procaine Penicillin G in Oil:** 300,000 units per cc. in sesame oil, 1 cc. vial.

Sterone Chemical Co., Inc., Jamaica 2, N. Y.

**Crystalline Procaine Penicillin G (Micronized) in Oil:** 300,000 units per cc. in sesame oil with aluminum monostearate 2 per cent, 10 cc. vials.

**STREPTOMYCIN** (See New and Nonofficial Remedies 1949, p. 159).

The following dosage form has been accepted:

Bio-Ramo Drug Co., Baltimore 1

**Streptomycin Calcium Chloride Complex:** 20 cc. vials containing streptomycin calcium chloride complex equivalent in activity to 1 Gm. of streptomycin base.

**SULFADIAZINE-U. S. P.** (See New and Nonofficial Remedies 1949, p. 134).

The following dosage form has been accepted:

Marvin R. Thompson, Inc., Stamford, Conn.

**Suspension Sulfadiazine with Sodium Lactate:** 473 cc. and 3.78 liter bottles. A liquid suspension containing 0.5 Gm. sulfadiazine and 1.5 Gm. sodium lactate per 5 cc.

**SULFADIAZINE-SULFAMERAZINE COMBINED** (J. A. M. A., May 7, 1949, p. 21).

The following dosage forms have been accepted:

Pitman-Moore Company, Indianapolis 6

**Magmoid Sulfadimer with Sodium Lactate:** 0.5 Gm. per 5 cc., 59.15 cc., 354.9 cc. and 3.78 liter bottles. A suspension containing 1.5 Gm. sulfadiazine, 1.5 Gm. sulfamerazine and 3 Gm. sodium lactate per 30 cc. solution.

The Warren-Teed Products Company, Columbus 8, Ohio

**Suspension Bi-Sulfazine:** 0.5 Gm. per 5 cc., 473 cc. and 3.785 liter bottles. A suspension containing 1.5 Gm. sulfadiazine and 1.5 Gm. sulfamerazine per 30 cc. solution.

**TESTOSTERONE PROPIONATE-U. S. P.** (See New and Nonofficial Remedies 1949, p. 407).

The following dosage forms have been accepted:

Rare Chemicals, Inc., Harrison, N. J.

**Solution Testosterone Propionate in Oil:** 10 mg. per cc. in sesame oil, 10 cc. vials. Preserved with phenyl mercuric borate 1 : 50,000.

**Solution Testosterone Propionate in Oil with Benzyl Alcohol 3%:** 50 mg. per cc. in sesame oil, 10 cc. vials. Preserved with phenyl mercuric borate 1 : 50,000.

Smith-Dorsey Company, Lincoln, Neb.

**Solution Testosterone Propionate in Oil with Benzyl Alcohol 3%:** 25 mg. per cc. in persic oil, 10 cc. vials.

***d*-TUBOCURARINE CHLORIDE** (See New and Nonofficial Remedies 1949, p. 210).

The following dosage form has been accepted:

Endo Products, Inc., Richmond Hill 18, N. Y.

**Solution *d*-Tubocurarine Chloride:** 3 mg. (20 units) per cc., 10 cc. vials. Preserved with chlorobutanol 0.5 per cent.

# Council on Physical Medicine and Rehabilitation

*The Council on Physical Medicine and Rehabilitation has authorized publication of the following reports.*

Howard A. Carter, *Secretary.*

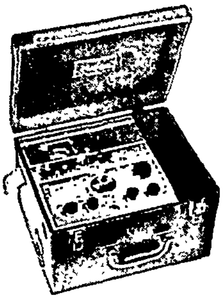
## CARDIOTRON, MODEL PC-2, ACCEPTABLE

Manufacturer: Electro-Physical Laboratories, Inc., 290 Dyckman Street, New York 34.

The Cardiotron, Model PC-2, is a direct-writing electrocardiograph in a portable case. As normally supplied it operates on 60 cycle alternating current at 100 to 130 volts. It draws a current of 0.85 ampere.

The dimensions of the cabinet are 22 by 31 by 37 cm. (8¾ by 12 by 14⅝ inches). Rubber bumpers add ½ inch to the height and width, and a carrying handle adds ⅞ inch to the width. The complete assembly, including all accessories, weighs 14.5 Kg. (32 pounds); the shipping weight is 20 Kg. (45 pounds).

The accessories are one 7-lead patient cable, four large electrodes, three small electrodes, four wrist bands, a chest band, tube of electrode jelly, roll of Permograph paper and reel, ground wire, emery board, two spare power line fuses, power cable, electrode jelly brush and protective cloth covering.



Cardiotron, Model PC-2

The apparatus was tested both physically and clinically in laboratories acceptable to the Council, and was found to satisfy the published requirements for acceptance of electrocardiographs. The Council on Physical Medicine and Rehabilitation voted to include the Cardiotron, Model PC-2, in its list of accepted devices.

## MCKESSON WATERLESS METABOLOR, MODEL 185, ACCEPTABLE

Manufacturer: McKesson Appliance Company, 2226-2236 Ashland Avenue, Toledo 10.

The McKesson Waterless Metabolor, Model 185, is a bellows type apparatus with an electrically driven timing device. The bellows is circular in form and opens somewhat like a book; it is completely housed within a white case, so that its movements are evident only to the technician by way of a pointer called the Bellows Position Indicator. A soda lime container is mounted outside the Metabolor proper so as to facilitate the removal of exhausted absorbent; a color indicator in a small glass cylinder where it can be seen by the technician changes from bright green to dark brown when the soda lime approaches saturation with carbon dioxide.

The weight of the apparatus is given as 30 Kg. (65 pounds) and the over-all dimensions are 112 by 43 by 58 cm. (44 by 17 by 23 inches). Accessories include ink, two face hoods, head harness, two mouthpieces, a nose clamp, a tank wrench, a spanner wrench and a nomographic calculator made of cardboard. The shipping weight is 34 Kg. (75 pounds). The motor in the Metabolor submitted to the Council required a 110 volt alternating current and drew 2 watts of power, but the firm states that this unit is manufactured for all voltages and cycle frequencies ordinarily encountered in alternating current and also for direct current.

This device has a disadvantage which it shares with other waterless metabolimeters already accepted by the Council; namely, that it is difficult to verify the correctness of the volume readings. It is inconvenient to measure directly the volume of air expelled when the bellows is compressed, and practically impossible to calculate it. This is deplorable in view of the low reliability of basal metabolic rates, as noted in The Journal, March 22, 1941, pages 1187 to 1195, and the *Quarterly Bulletin, Northwestern University Medical School* (19: 105-110, 1945). It also impairs the value of waterless metabolimeters as equipment for demonstration and teaching. However, the fact that friction is less in a bellows and that the patient cannot see the movements inside the housing probably makes for a smoother respiratory tracing.

The Council on Physical Medicine and Rehabilitation voted to include the McKesson Waterless Metabolor, Model 185, in its list of accepted devices.

## NEGATIVE PRESSURE SINUS UNIT ACCEPTABLE

Manufacturer: Inhalational Equipment Company, 248 East 119th Street, New York 35.

The Negative Pressure Sinus Unit is a device made of Pyrex glass and designed to connect with various accessories (oxygen tank, oxygen regulator, rubber hand bulb, nebulization foot pump, tubing and stoppers) in such a way that an intermittent suction can be produced in the nasal passages and accessory sinuses; the periodic release of the suction is intended to cause a brief influx or puff of aerosol into the sinuses. Frequent alternations between suction and normal pressure will produce a series of inflows of medicated air into the sinuses until a considerable amount of aerosol is introduced.

The weight of the device is about 85 Gm. (3 ounces); the shipping weight is about 200 Gm. (7 ounces), and the over-all dimensions are 23 by 23 by 8 cm. (9 by 9 by 3 inches).

The Council secured evidence that this device produces a satisfactory mist and that with its use medication can be induced to enter a sinus if the aperture is patent. The Council, therefore, voted to include the Negative Pressure Sinus Unit in its list of accepted devices with the understanding that the claims for any drugs used with this unit be confined to those found acceptable by the Council on Pharmacy and Chemistry.

## DWYAD PORTABLE OXYGEN UNIT FOR AEROSOL MEDICATION ACCEPTABLE

Manufacturer: The Penicillin Machine Company, Box 751, Cleveland 22.

The Dwyad Portable Oxygen Unit for Aerosol Medication is a device that uses compressed oxygen from a tank for the purpose of nebulizing aqueous medicaments. It consists of a light weight nonshatterable tank with working mechanism attached to the nebulizer, so that the inhalation can be taken in through either mouth or nose as desired.

The assembly weighs 4.5 Kg. (10 pounds), and the shipping weight is 5.4 Kg. (12 pounds). The over-all dimensions are 20 by 20 by 89 cm. (8 by 8 by 35 inches).

Evidence was obtained that the apparatus performed as represented by the manufacturer.

The Council on Physical Medicine and Rehabilitation voted to include the Dwyad Portable Oxygen Unit for Aerosol Medication in its list of accepted devices.

# Council on Foods and Nutrition

*The following products have been accepted as conforming to the Rules of the Council.*

James R. Wilson, M.D., *Secretary.*

**The National Drug Company, Philadelphia.**

Protinal—Chocolate Flavored consists of high nitrogen casein, cocoa, saccharin, coumarin and powdered sugar.

*Analysis* (submitted by manufacturer).—Total nitrogen 9.7 per cent, carbohydrate 24.0 per cent, moisture 5.0 per cent, ether extractables 1.0 per cent, sodium 0.03 per cent.

*Calorics.*—3.4 per gram; 102 per ounce.

*Vitamins.*—No vitamin claims are made, but water-soluble vitamins of milk are contained in the product.

*Use.*—A whole protein supplement for oral use when extra protein or a concentrated source of protein is required in the diet.

Protinal—Vanilla Flavored consists of high nitrogen casein, coumarin, vanillin and powdered sugar.

*Analysis* (submitted by manufacturer).—Total nitrogen 9.7 per cent, carbohydrate 30.0 per cent, moisture 5.0 per cent, ether extractables 0.5 per cent, sodium 0.03 per cent.

*Calorics.*—3.60 per gram; 108 per ounce.

*Vitamins.*—No vitamin claims are made, but water-soluble vitamins of milk are contained in the product.

*Use.*—Whole protein supplement for oral use when extra protein or a concentrated source of protein is required in the diet.

SATURDAY, AUGUST 27, 1949

## INDUSTRIAL POLLUTION OF HUMAN ENVIRONMENT

The survival of man depends on his ability to adapt himself to his environment. For thousands of years changes in man's environment resulted from natural causes beyond his control; he tried to mitigate their impact by migrating from regions that had become unfavorable to regions more favorable. Such attempts were not always successful, for various types of primitive man disappeared. About one hundred years have passed since modern man first experimented in modifying his natural environment by the addition of numerous new and often artificial products created by modern industry. Occupational diseases furnish a vivid example of the many and frequently serious new health hazards to which the industrially employed part of mankind has become exposed. The inclusion of some of these agents in consumer goods, such as foodstuffs, cosmetics, medicines, household goods and clothing, and their sometimes indiscriminate use have brought the general population into close contact with the injurious factors in the modern industrial environment. Perhaps the most important and alarming aspect of the recent change in human environment is the increasing and often severe pollution of the air, soil and water with both industrial wastes and regular products of industrial manufacture, such as pesticides and coal and petroleum road tars and asphalts, injurious to human health. The recent disaster at Donora called attention to the problem of air pollution by industrial gases and fumes containing sulfur dioxide, arsenic and fluorine, originating from smelters.

Experiences in the environment of some large copper smelters in the Rocky Mountain area attest that human beings are not the only potential victims of toxic industrial wastes released into the atmosphere. Fumes and gases from petroleum refineries are obnoxious to the people living in their environs; their odors are offensive and even nauseating. Such fumes contribute to the formation of the "smog" encountered in the Los Angeles area and give rise to irritation of the eyes and the respiratory tract. Coke ovens and other industrial plants are a source of excessive production of soot and sulfur dioxide from the burning of coal. Considerable amounts of soot are released into the air during the production of carbon black from natural gas or mineral oil and during the burning of waste oil residues near oil refineries. The potential carcinogenic properties of soot are well established by numerous animal experiments and are supported by the occurrence of cancer of the skin in chimney sweeps. Apparently health hazards of various types exist for the population living in the immediate environment of other industrial establishments through air pollution with wastes.

Prolonged sterilization of the soil has been produced by the deposition of arsenicals from smelter fumes or as insecticides. In a few instances such soil pollution by arsenic-containing industrial wastes has resulted in the contamination of the drinking water supply with toxic amounts of arsenicals. The extensive pollution of rivers and lakes with industrial wastes and urban unprocessed sewage has converted many bodies of public water into unwholesome cesspools, dangerous to any form of life dependent on them as normal environment or for water supply.

People are usually slow in reacting forcefully and effectively to gradually developing conditions injurious to health and survival. Some acute disaster is needed to arouse attention to such environmental health hazards and to force remedial action. The recent Donora disaster served in this role regarding industrial air pollution and brought about the realization, repeatedly voiced at the recent symposium on air pollution held at the Atlantic City meeting of the American Medical Association, that mankind has entered a new world of environmental conditions giving rise to serious health problems. Although acute mass disasters from environmental pollution by industrial wastes are spectacular events because of the number of deaths and diseased persons encountered, such catastrophies occur rather infrequently as the result of unusually massive exposures and are therefore of lesser importance than more widespread and less obvious injuries to health occasioned by the prolonged action of smaller concentrations of the environmental injurious agents on larger population groups. The type and degree of health hazards produced by such exposures is not readily ascertained. Often the symptoms produced are noncharacteristic and may be easily confused with those seen with bacterial infections, nonindustrial allergies or constitutional anomalies. Such insidious and often rather moderate effects on health are of distinct importance at times of more massive exposures, since they lower the resistance of the exposed persons to the higher doses and thereby tend to cause more severe reactions than those that might be elicited in persons not preconditioned by previous contact with low doses of the injurious environmental agents. The extent to which such predisposing factors have been active may determine to a large degree the severity of the reactions and of the disaster seen with massive transitory exposures.

## PHOTOFLUOROGRAPHY IN GASTRIC CARCINOMA

Recent statistical studies by Dorn,[1] quoted by Roach and his associates,[2] indicate that gastrointestinal cancer develops in approximately 60,000 men and 42,000 women above the age of 40 each year in the United States. Of these more than one half die within one year of the time that the diagnosis is made. Persons who do not survive the disease account for nearly half of the deaths resulting from all types of cancer and 5 per cent of the deaths occurring from any cause. In men, nearly 40 per cent of the tumors arising in the digestive system are gastric in origin. In women, 30 per cent of such lesions lie within the stomach. According to Dorn [1] the average length of life following the recognition of the disease is about one year and eight months regardless of therapy. Although surgical treatment is the method of choice in cancer of the stomach, the average five year survival rate of patients operated on is about 5 per cent even when optimum surgical methods are employed. Pack [3] has found that approximately 50 per cent of patients who have gastric cancer are inoperable when the disease is first diagnosed. Of the remainder almost one half present unresectable lesions. Thus only 25 per cent of persons with gastric cancer have any chance of benefit from surgical intervention. Of these, one third do not survive operation, and of those who do recover over two thirds die from recurrent disease or from other causes within a few years. Thus the average five year survival rate for patients with gastric cancer shrinks to 5 per cent.

If surgical intervention is to achieve better results the recognition of the disease must occur early in its development. Roach and his associates believe that the early diagnosis of gastric cancer is a problem of finding those asymptomatic persons in the general population who have the disease. The roentgenologic method constitutes today the most reliable diagnostic procedure for the examination of the stomach. Gastroscopy and examination of the gastric contents for malignant cells according to the method of Papanicolaou are helpful but not of practical value when large numbers of persons are to be examined. Furthermore, both gastroscopy and aspiration are cumbersome and unpleasant methods so far as the patient is concerned. Roentgenoscopy and roentgenography are slow procedures requiring prolonged services of a highly trained physician. These methods therefore are impractical for mass examination of the stomach. Roach and his co-workers point out that photofluorography, which has been so successful in the early detection of pulmonary lesions, offers the advantages of being inexpensive and rapid in execution and not requiring the services of a fluoroscopist. The disadvantages of the method, such as the excessively large doses of radiation that until now have been necessary to produce satisfactory photofluorograms, have now been overcome by the application of Schmidt optics to photofluorographic camera equipment. Utilizing a camera of the Schmidt type, one can now make photofluorograms of the stomach with a little more exposure than that used in conventional roentgenography. The application of Schmidt optics to photofluorography by the Danish engineer Helm resulted in the development of two cameras, one using 35 mm. perforated film and the other using 70 mm. perforated film. Models of both cameras have been brought to the United States by the Tuberculosis Control Division, United States Public Health Service. Morgan and his associates [4] point out that the principal advantage of cameras of the Schmidt type is their greater speed. Thereby power requirements for the roentgen ray generator are lessened, tube life is extended and radiation dosage to the patient is reduced. The cameras may be used for cineroentgenography and photofluorography of such structures as the abdomen, the gastrointestinal tract and the osseous system.

The reliability of gastric photofluorography is under test by Roach and his co-workers, who have established a pilot survey at the Johns Hopkins Hospital in which all patients above the age of 40 who are admitted to the dispensary outpatient clinic of the hospital during the course of the study will be examined photofluorographically for gastric changes. These authors point out that according to recent statistics one may expect to find only 1 man with gastric cancer in every 700 men studied; in women, the expectant prevalence of the disease is 1 in every 1,200. It is anticipated that within each year of the study between 5,000 and 10,000 patients will be examined and that a minimum of six to twelve gastric carcinomas will pass through the unit. The number of persons whom one may expect to find with carcinoma of the stomach in general population groups of men and women above 40 is approximately 1 in 900. While such an incidence may seem small, in reality it is only slightly less than that of significant pulmonary tuberculosis among the general population, which is 1 in 300 to 500. The survey will cover approximately five years. During this time all patients with abnormal photofluorograms will be restudied with conventional roentgenoscopic technics. Those who present changes suggesting gastric cancer will be operated on. A group of approximately 1,000 asymptomatic persons will be examined photofluorographically for gastric changes at intervals of six months. From this study an estimate of the interval at which photofluorographic examinations should be repeated in the general population may be determined.

### FATE OF INSULIN IN THE NORMAL AND DIABETIC ORGANISM

Little has been known of the ultimate fate of insulin in the human organism. Obviously, insulin is constantly being eliminated; otherwise cumulative effects manifested by periods of severe hypoglycemia would be observed even in normal subjects. As is well known, however, the blood sugar level is maintained remarkably constant in normal persons. At least two different methods of disposing of insulin appear possible: one by excretion in the urine or possibly feces (via bile) and the other by destruction in the body. The first route, that of excretion, would not appear to be of major importance. The elimination of protein molecules as large as that of insulin (molecular weight 35,000) seldom takes place to any significant extent in the normal kidney and probably not in the bile or feces. Support for this statement is to be found in a recent study[1] in which it was reported that the urine of normal human subjects contains slightly less than 1 unit (0.66 plus or minus 0.04) of insulin per day. Moreover, persons with mild diabetes who were not receiving insulin excreted even less insulin daily and either normal or diabetic subjects given exogenous insulin excreted only minute amounts.

The Ohio investigators also reported the interesting observation that insulin-resistant patients who received large amounts of exogenous insulin appeared to excrete even less insulin in the urine than normal or diabetic subjects. This observation may be significant in elucidating the etiologic aspects of the disease. The foregoing studies thus appear to warrant the conclusion that urinary excretion is not an important pathway for the metabolic disposal of insulin.

Further studies by the Cincinnati group,[2] however, have furnished more definite information on this subject. Aqueous extracts of certain tissues of various animals and man were found to destroy insulin rapidly on incubation. The liver was particularly rich in the substance, and kidney and muscle contained smaller amounts. None was found in brain, whole blood or plasma. As the insulin-inactivating substance was found to be thermolabile and to be inactivated by typical enzyme inhibitors, the investigators believe that the substance is an enzyme and have suggested the name "insulinase." In further studies, fasting produced a definite reduction in the insulinase activity of the liver (rat) just as others have shown to be true of the insulin content of the pancreas. This suggests a relationship between insulin secretion by the pancreas and insulinase secretion by the liver so that a delicate balance between the two may be maintained. The work also suggests that the destruction of insulin by insulinase, particularly in the liver, is the primary means of the disposal of insulin in the animal organism. Further studies on this interesting and important problem may well prove of value in elucidating the etiology of obscure diseases of carbohydrate metabolism such as insulin resistance.

## Current Comment

### SENATE REJECTS REORGANIZATION PLAN NO. 1

The United States Senate on August 16 voted 60 to 32 to pass the Fulbright-Taft resolution, S. 147, which rejects the President's Reorganization Plan No. 1. The senators who voted for the resolution were well aware that the health of the public could not be adequately served by a subsidiary section of an elevated Department of Welfare. Apparently the intensive drive made by the present Federal Security Administrator in behalf of nationalized medicine influenced the Senate against the measure which would have made him supreme over government medical services. The Senate, it is reported, resisted heavy executive and political pressure in taking this decisive action.

### AUREOMYCIN TREATMENT OF AMEBIASIS

In treating several cases of bacterial infection with aureomycin, McVay[1] and his associates of the University of Tennessee noted alterations in the gross character of the stools. There was a definite reduction in the fecal bacterial count. This local effect led them to test the possible value of aureomycin in the treatment of amebiasis, then prevalent in the Memphis area. Thus far 14 patients with amebiasis have been treated with aureomycin. In a typical case both trophozoite and cystic forms of Endamoeba histolytica were found in the stools of a patient suffering from paraumbilical pain, abdominal fulness and constipation. The patient was given 6.75 grains (439 mg.) of aureomycin orally in divided doses over a period of three days, at the end of which time his stools had become normal. The treatment was continued until the patient had been given a total of 21.75 grains (1,414 mg.) of aureomycin. During treatment the aureomycin blood level reached 8 micrograms per hundred cubic centimeters and all gastrointestinal symptoms disappeared. Results of fourteen subsequent stool examinations over a period of three weeks have been negative. McVay believes that a much larger number of cases with adequate follow-up will be necessary before a final evaluation can be made of the value of aureomycin in the treatment of amebiasis. The high aureomycin blood level observed in his cases leads him to believe that aureomycin therapy will be successful in extraintestinal amebic infections, such as hepatic abscess.

# ORGANIZATION SECTION

## *Washington Letter*

*(From a Special Correspondent)*

Aug. 22, 1949.

### Hearings for McCarthy's Department Bill

Shortly after the Senate's defeat of President Truman's plan for a Department of Welfare, an official spokesman for the Senate Expenditures Committee disclosed that public hearings might be scheduled in the near future on S. 2060. This is the bill, sponsored by Senator Joseph R. McCarthy (R. Wis.), which would establish a Department of Health, Education and Security. It is identical to S. 140, on which hearings were held in 1947.

Meantime, in view of the lateness of this session of Congress, it is doubtful whether the Administration will press for enactment of H. R. 782, which would set up a Department of Welfare along lines of the defeated Reorganization Plan No. 1. Capitol observers believe, however, that, if the Senate Expenditures Committee goes through with its plans for hearings on S. 2060, witnesses supporting Administration policies will revive the House bill and urge its enactment over the McCarthy measure.

### Plans Advance for Lobbying Investigation

That there will be a congressional investigation of lobbying activities appears to be reasonably certain, although whether it will be conducted jointly by Senate and House or by the House alone is still in doubt. The House has passed a resolution which provides that the inquiry shall be conducted by a select committee of seven representatives appointed by the Speaker. Meantime, however, the Senate has under consideration a separate resolution, favorably reported by its Rules Committee, which calls for the investigation to be held by a committee of five Senators and five representatives who would be appointed by the chairmen of the Senate and House judiciary committees.

### School Health Services Bill Ensnarled in Committee

The House Interstate and Foreign Commerce Committee conducted several executive sessions the third week in August in an attempt to agree on changes in the school health services bill (S. 1411), which passed the Senate last April. However, a final draft was not achieved and further meetings were to be held. Under consideration also by the same committee is legislation on federal aid for local public health units and liberalization of the Hill-Burton Hospital Survey and Construction Act. The former has been favorably reported to the Senate, and the hospital bill was passed by the Senate August 9.

### Increased Funds for W.H.O. Approved

Awaiting action on the House calendar is H. J. Res. 334, one of the provisions of which is to raise the ceiling on this country's annual contribution to World Health Organization to $3,000,000. At present it is $1,920,000. The resolution was favorably reported to the House in mid-August by the Foreign Affairs Committee. Its sponsor is Representative Thomas E. Morgan (D., Pa.), a physician. Among those who presented arguments in behalf of the larger appropriation was Dr. James R. Miller, Hartford, Conn., who served as a member of the United States delegation to the Second World Health Assembly in Rome last June.

### Murray Subcommittee Approves Three Federal Security Agency Bills

The Senate subcommittee on health matters, of which Senator James E. Murray (D., Mont.) is chairman, has approved three bills pertaining to Federal Security Agency administrative policies and forwarded them to the Labor and Public Welfare Committee. They are S.1706, S.2227 and S.2228. In that order, they clarify eligibility of persons living in the Virgin Islands for admittance to St. Elizabeth's Hospital, the federal institution for mental diseases in the District of Columbia; provide for reallocation of venereal disease rapid treatment facilities, and authorize acceptance by Public Health Service hospitals of certain patients committed by state courts.

### Efforts Pushed to Rescind Cutback in Veterans Hospitals

Representatives John Rankin (D., Miss.) and Charles E. Bennett (D., Fla.) are the latest to attempt to have Congress direct the Veterans Administration to abandon its plans for a 16,000 bed cutback in its hospital construction program. Both have introduced bills to that effect. On the other side of Capitol Hill, the leader in the campaign for restoration of the original construction program is Senator Claude Pepper (D., Fla.). The second and last volume of testimony presented at public hearings last spring on the cutback is now available and may be obtained from the Senate Labor and Public Welfare Committee.

## *Coming Medical Meetings*

Aero Medical Association, New York, Aug. 29-Sept. 2. Dr. Thomas H. Sutherland, 214 S. State St., Marion, Ohio, Secretary.

American Academy of Ophthalmology and Otolaryngology, Chicago, Oct. 9-14. Dr. W. L. Benedict, 100 First Avenue Bldg., Rochester, Minn., Secretary.

American Association of Obstetricians, Gynecologists and Abdominal Surgeons, Hot Springs, Va., The Homestead, Sept. 8-10. Dr. Leroy A. Calkins, University of Kansas Medical Center, Kansas City 3, Kan., Secretary.

American College of Surgeons, Chicago, Stevens Hotel, Oct. 17-21. Dr. Paul B. Magnuson, 40 E. Erie St., Chicago 11, Secretary.

American Congress of Physical Medicine, Cincinnati, Netherlands Plaza Hotel, Sept. 6-10. Dr. Richard Kovacs, 2 E. 88th St., New York 28, Secretary.

American Hospital Association, Cleveland, Sept. 26-29. Mr. George P. Bugbee, 18 East Division St., Chicago, Executive Secretary.

American Roentgen Ray Society, Cincinnati, Oct. 4-7. Dr. H. Dabney Kerr, University Hospitals, Iowa City, Iowa, Secretary.

American Society of Clinical Pathologists, Chicago, Drake Hotel, Oct. 11-15. Dr. C. G. Culbertson, 740 S. Alabama St., Indianapolis, Secretary.

Colorado State Medical Society, Denver, Shirley-Savoy Hotel, Sept. 20-23. Mr. Harvey T. Sethman, 835 Republic Bldg., Denver, Executive Secretary.

Delaware, Medical Society of [illegible] Dr. W. Edwin Bird, 822 North American [illegible] Secretary.

District of Columbia, Medical [illegible] Hotel Statler, Oct. 17-19. Mr. Theodore [illegible] Washington 6, Secretary.

Gulf Coast Clinical Society, Pensacola, Fla., Oct. 6-7. Dr. Arthur J. Butt Jr., 1101 N. Palafox St., Pensacola, Fla., Secretary.

Indiana State Medical Association, Indianapolis, Sept. 26-29. Mr. Ray E. Smith, 1021 Hume-Mansur Bldg., Indianapolis 4, Executive Secretary.

International Neurological Congress, Paris, France, Sept. 5-10. Dr. Raymond Garcin, 19 rue de Borgogne, Paris, General Secretary.

Kansas City Southwest Clinical Society, Kansas City, Mo., Municipal Auditorium, Oct. 3-6. Dr. W. Merritt Ketchum, 630 Shukert Bldg., Kansas City, Mo., Secretary.

Kentucky State Medical Association, Owensboro, Oct. 6-9. Dr. Bruce Underwood, 620 S. Third St., Louisville 2, Secretary.

Michigan State Medical Society, Grand Rapids, Pantlind Hotel and Civic Auditorium, Sept. 21-23. Dr. L. Fernald Foster, 2020 Olds Tower, Lansing 8, Secretary.

Mississippi Valley Medical Society, St. Louis, Jefferson Hotel, Sept. 28-30. Dr. Harold Swanberg, 209-224 W. C. U. Bldg., Quincy, Ill., Secretary.

Neurological Society of America, Quebec, Canada, Chateau Frontenac, Oct. 17-19. Dr. Edward Schlesinger, 710 W. 168th St., New York, Secretary.

Nevada State Medical Association, Elko, Sept. 29-Oct. 1. Dr. Roland W. Stahr, 118 California Ave., Reno, Secretary.

Northern Minnesota Medical Association, Alexandria, Sept. 9-10. Dr. C. L. Oppegaard, Crookston, Secretary.

Oregon State Medical Society, Eugene, Oct. 12-15. Dr. Werner E. Zeller, Medical-Dental Bldg., Portland 5, Secretary.

Pennsylvania, Medical Society of the State of, Pittsburgh, Hotel William Penn, Sept. 26-29. Dr. W. F. Donaldson, 8104 Jenkins Arcade, Pittsburgh 22, Secretary.

Southern Minnesota Medical Association, Red Wing, Sept. 12. Dr. W. A. Merritt, 102 Second Ave. S.W., Rochester, Secretary.

Southwestern Surgical Congress, Houston, Tex., Shamrock Hotel, Sept. 26-28. Dr. C. R. Rountree, 1200 N. Walker St., Oklahoma City, Secretary.

Utah State Medical Association, Salt Lake City, Sept. 1-3. Dr. Ray T. Woolsey, 42 S. Fifth East St., Salt Lake City 2, Secretary.

Vermont State Medical Society, Burlington, Sept. 8-9. Dr. James P. Hammond, 542 Main St., Bennington, Secretary.

Virginia, Medical Society of, Fort Monroe, Old Point Comfort, Oct. 9-12. Miss Agnes V. Edwards, 1200 E. Clay St., Richmond, Sechetary.

Washington State Medical Association, Seattle, Olympic Hotel, Sept. 11-14. Dr. James W. Haviland, 338 White-Henry-Stuart Bldg., Seattle, Secretary.

Western Orthopedic Association, Santa Barbara, Calif., Biltmore Hotel, Oct. 19-21. Dr. Charles W. Gilfillan, 1680 N. Vine St., Hollywood, Calif., Secretary.

Wisconsin, State Medical Society of, Milwaukee, Hotel Schroeder and Milwaukee Auditorium, Oct. 3-5. Mr. Charles H. Crownhart, 704 E. Gorham St., Madison, Secretary.

World Medical Association, General Assembly, London, Eng., Oct. 10-15. Dr. Louis H. Bauer, 2 E. 103d St., New York City, Secretary General.

Wyoming State Medical Society, Casper, Sept. 12-14. Dr. George H. Phelps, 1606 Capitol Avenue, Cheyenne, Secretary.

## PUBLIC HEALTH SERVICE

### HISTORY OF PLAGUE IN THE U. S.

The communicable disease center at Atlanta, an agency of the U. S. Public Health Service, has published in its bulletin an illustrated history of plague in the United States, along with other articles on the treatment and control of plague. The following chart, including that of Hampton's in *Public Health Reports* of Nov. 16, 1945, shows the number of cases and deaths from plague up through 1947.

| YEAR | CASES | | | | | | | | | TOTALS | |
|---|---|---|---|---|---|---|---|---|---|---|---|
| | CALIF. | WASH. | LA. | FLA. | TEX | OREGON | UTAH | NEV. | IDAHO | CASES | DEATHS |
| 1900 | 22 | | | | | | | | | 22 | 22 |
| 1901 | 30 | | | | | | | | | 30 | 26 |
| 1902 | 41 | | | | | | | | | 41 | 41 |
| 1903 | 17 | | | | | | | | | 17 | 17 |
| 1904 | 10 | | | | | | | | | 10 | 8 |
| 1905-06 | | | | | | | | | | 0 | 0 |
| 1907 | 178 | 3 | | | | | | | | 181 | 90 |
| 1908 | 8 | | | | | | | | | 8 | 5 |

** 1945-1946 data from Public Health Reports for 1945, 1946, and 1947. One case occurred in California in 1947

CASES OF, AND DEATHS FROM, PLAGUE IN THE UNITED STATES (HAMPTON, 1945)

### DR. VELDEE RETIRES

Dr. Milton V. Veldee, who had been detailed for twenty years to the National Institute of Health, is now on terminal leave in anticipation of his retirement. His various assignments during the years included service with the American Red Cross in Russia in 1920, medical advisor to the American Consul in Denmark and chief of the Laboratory of Biologics Control since 1931 of the National Institute of Health. His successor at the Institute is Dr. William G. Workman, who also has been with the institute for many years. Dr. Workman was a consultant in preventive medicine to the U. S. Army in Korea and Japan, and an advisor to the military governments in those countries in 1946. At present he is a consultant at the Research and Development Board of the National Military Establishment.

### EXAMINATION OF IMMIGRANTS

On July 25, Senior Surgeon Ralph Gregg, assistant chief of the Division of Foreign Quarantine, flew to Europe for a month's inspection of the service offices where applicants for United States immigration visas undergo medical examination. Dr. Gregg was accompanied in Europe by Medical Director Lynne A. Fullerton, who is assigned to the American Embassy in Paris as supervisor of the service's immigration medical work in Europe.

Public Law 774 of 1948 authorizes immigration of 205,000 displaced persons in a two year period. Public Health Service officers serve as medical examiners and report applicants with disease excludable under immigration laws (mental diseases, tuberculosis in any form, contagious diseases and physical defects which may affect ability to earn a living).

Dr. Frank M. Faget is completing thirty-five years' service as medical officer with the Public Health Service and will retire Nov. 1, 1949. Dr. Faget, now on terminal leave, has been medical officer in charge of the Portland (Maine) Marine Hospital for the last two years. Succeeding him in that post is Dr. P. D. Mossman, formerly medical officer in charge at the Seattle Marine Hospital.

### DR. KINSEY APPOINTED PHARMACIST DIRECTOR

Dr. Raymond Kinsey has been appointed to the rank of pharmacist director of the Public Health Service. Dr. Kinsey is the first pharmacist officer to be appointed to the director grade in the history of the Public Health Service, according to Surgeon General Leonard A. Scheele. The director grade is the equivalent of the full colonel rank in the Army.

### EXAMINATIONS FOR MEDICAL OFFICERS

Examinations will be held October 3-5 for physicians and veterinarians seeking appointment in the Regular Corps of the Public Health Service as medical officers and public health and research veterinarians. Examinations will be held in the following cities: Baltimore, Fort Worth, New Orleans, Memphis, Lexington, Atlanta, Boston, Buffalo, Chicago, Cleveland, Detroit, Los Angeles, San Francisco, Seattle, Denver and Kansas City, Mo., and other cities throughout the country. Applicants have until September 5 to submit their papers. Applications and requests for information should be addressed to the Public Health Service, Federal Security Agency, Washington 25, D. C., Attention: Division of Commissioned Officers.

### PERSONAL

Dr. Alexander D. Langmuir has been appointed chief of the Epidemiology Division of the Communicable Disease Center of the Public Health Service. Dr. Langmuir has begun his duties at the Communicable Disease Center in Atlanta, Ga. Before his appointment Dr. Langmuir was associate professor of epidemiology for three years at the Johns Hopkins University School of Hygiene and Public Health.

# Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

## COLORADO

**State Medical Society Meeting.**—The annual session of the Colorado State Medical Society will be held at the Hotel Shirley-Savoy, Denver, September 20-23, under the presidency of Dr. Casper F. Hegner, Denver. Physicians invited to address the scientific sessions include:

Phillips Thygeson, San Jose, Calif., Recent Advances in Our Knowledge of the Etiology and Treatment of Uvietis.
Edward L. Compere, Chicago, Office Management of the More Common Foot Problems of Children.
Herbert A. Wenner, Kansas City, Kan., Recent Advances in the Research of Poliomyelitis.
Charles H. Slocumb, Rochester, Minn., Rheumatoid Arthritis.
Rubin H. Flocks, Iowa City, Some Aspects of the Etiology and Medical Management of Renal Stone.
Perry P. Volpitto, Augusta, Ga., Anesthesia and Analgesia in Obstetric Labor.
Frank H. Lahey, Boston, Management of Lesions of the Stomach, Duodenum and Jejunum.
Mr. William A. Richardson, Rutherford, N. J., First Year of the British National Health Service.

Scientific and technical exhibits will be displayed. A full color television program will be shown through the courtesy of Smith, Kline and French Laboratories of Philadelphia. The annual banquet and dance will be held Friday evening.

## CONNECTICUT

**Insect Survey.**—Field workers are conducting an insect survey in New Haven, Hartford, New Britain, Meriden and Bridgeport this summer under the direction of scientists from Yale University School of Medicine, New Haven. This is a continuation of a program of work started last year. Representatives are spending several days each week in these cities to trap large quantities of "non-biting flies." The insects are used in connection with the continuing studies of viruses being made under the direction of Joseph L. Melnick, Ph.D., associate professor of microbiology at Yale University and Lawrence R. Penner, Ph.D., assistant professor of zoology and entomology at the University of Connecticut, Storrs. This research is sponsored by the National Foundation for Infantile Paralysis, Inc., but it is a part of Yale University's long range program on the relationship between insects and virus diseases now in its eleventh year. The Connecticut insect survey is also part of a similar nationwide program being undertaken in several states this year.

## ILLINOIS

**Postgraduate Lecture.**—The Scientific Service Committee of the Illinois State Medical Society has arranged a lecture for the St. Clair County Medical Society at East St. Louis September 1, when Dr. Joseph H. Kiefer, Chicago, will speak on "Carcinoma of the Prostate." The Sangamon County Medical Society, meeting in Springfield September 1, will hear Dr. Philip Thorek, Chicago, speak on "Portal Hypertension."

### Chicago

**Grant to Crerar Library for Cancer Collection.**—The Illinois Division of the American Cancer Society has given its second annual grant of $1,500 to the John Crerar Library to increase its collection of cancer literature. All volumes in this collection are available to physicians and scientists specializing in the disease. The library now has about 90 per cent of all journals of current importance in the cancer field and through the proceeds of the grant hopes to accomplish close to complete coverage of cancer literature.

**Dr. Adams Heads Department of Medicine.**—Dr. Wright R. Adams, professor of medicine and associate dean of the Division of Biological Sciences at the University of Chicago, has been appointed chairman of the department of medicine. He will succeed Dr. Lowell T. [illegible] gned as chairman of the department of [illegible] vote full time to his post as dean of the [illegible] Sciences and to his research work in internal medicine and tropical diseases. Dr. Adams, a graduate of the University of Illinois College of Medicine, 1929, has been a member of the cardiac department of the University of Chicago Clinics since his appointment to the university in 1930. From 1928 to 1930 he was an intern at St. Luke's Hospital and in 1930 a volunteer in pathology at Cook County Hospital.

**Research Grants Awarded.**—Five research grants totaling $21,460 have been awarded to the University of Illinois College of Medicine. The Chicago Heart Association granted $10,000 to Dr. Carl C. Pfeiffer in the department of pharmacology for the study of the effects of stress and diet on the regulation of the flow of blood into the kidneys. The National Cancer Institute has renewed a grant of $5,940 for a study involving dyes and cancer of the stomach being conducted by Drs. Andrew C. Ivy and Francis T. Flood. A $2,500 grant has been received from the Roche Foundation in support of a research fellowship involving a continuation of the study of curare-like drugs, under the supervision of Dr. Klaus R. Unna. Abbott Laboratories has made a grant of $2,120 for a study of a synthetic sweetening agent which does not have caloric value, being conducted by Dr. Morton I. Grossman and Miss Charlotte Robertson. Hoffman-LaRoche Inc., has awarded a grant of $900 to subsidize pain tests involving the study of analgesic drugs, under the direction of Dr. Pfeiffer.

**Personals.**—Dr. James L. Fleming, obstetrician and gynecologist for 46 years, and Dr. George F. Thompson, a surgeon for 50 years and now chairman of the hospital surgical department, were given a testimonial dinner by the attending staff of St. Anne's Hospital June 15.——Dr. Frederick Steigmann, associate director in charge of clinical investigation, Hektoen Institute for Medical Research, has been appointed area consultant in gastroenterology to the Veterans Administration Hospitals in the Middle and Northwestern states.——Municipal Judge Jacob M. Braude has been appointed to succeed Dr. Anton J. Carlson as president and chairman of the Chicago Committee on Alcoholism. Dr. Carlson has been elected honorary president for life.——The distinguished service award of the University of Kansas, Kansas City, was presented to Dr. Warren H. Cole, professor of surgery at the University of Illinois College of Medicine, at recent graduation and alumni exercises. The award is presented annually by the university through its alumni association to graduates for distinguished service. Dr. Cole received the bachelor of science degree from Kansas in 1918. A year ago Dr. Cole served as Senior Scientist Attache for the United States mission to Britain for Science and Technology, which was conducted under the jurisdiction of the Department of State.

## IOWA

**Stream Pollution Law.**—Iowa has passed a new stream and lake pollution law giving the state department of health power to prevent pollution of the state's lakes and streams before it occurs. The law, effective July 4, states among other things that a permit must be issued before the building of a new sewer or a change is made in an existing plant which will empty into a stream or lake. It also requires treatment of domestic sewage and planning for proper disposal of pollutional industrial wastes before they are produced. The original law controlling stream pollution did not authorize the Iowa State Department of Health to prevent new pollution but merely to clean up the pollutional condition after it had occurred.

## KANSAS

**Kansas Division of Cancer Society Awards.**—Six awards will be made for scientific investigation, two each of $500, $300 and $100, by the Kansas Division of the American Cancer Society for work in fields related to growth, cause, diagnosis or treatment of cancer which has been done in the state. Contestants will be divided into two groups, those who have not received a doctorate degree and those who have received a doctorate degree since June 1944. All manuscripts should be submitted in triplicate, the author's name and address appearing on a separate sheet of paper. Further information may be secured from the Kansas Division of the American Cancer Society, 506 New England Building, Topeka, Kansas.

## KENTUCKY

**County Healthmobile Report.**—The Louisville-Jefferson County Board of Health Healthmobile has aided 1,201 county residents during its first six months of operation. According to Dr. David E. Booker, director of clinics, total visits numbered 2,224, of which 324 were infants; 1,456, preschool children; 298, school children; 84 morbidity and 55 prenatal cases.

**Personals.**—Dr. J. Duffy Hancock, Louisville, has been named Kentucky representative on the newly created council of the Southeastern Surgical Congress.——Dr. Ralph S. Metheny, Louisville, who is chief of medicine at Nichols General Hospital, will become manager August 21 of the new 200 bed Veterans Administration Hospital at Altoona, Pa. Dr. Ronald R. Kaplan, a 1932 graduate of the University of Louisville School of Medicine who is now in charge of the hospital's outpatient department, will be Dr. Metheny's successor.

## MARYLAND

**State Academy of General Practice Meeting.**—The first assembly of the Maryland Academy of General Practice will be held September 29 in Hagerstown. Out of state speakers include:

George M. Lyon, Washington, D. C., Radioactive Isotopes in Clinical Medicine.
Thomas H. McGavack, New York, Diseases of the Thyroid.
John B. Montgomery, Philadelphia, Office Gynecology.
Edward Scott O'Keefe, Lynn, Mass., A High Caloric Diet in the Treatment of Diarrhea in Infancy.
LeRoy H. Sloan, Chicago, Changing Patterns of Disease.

## MICHIGAN

**State Medical Society Meeting.**—The annual session and postgraduate conference of the Michigan State Medical Society will be held in the Pantlind Hotel and Civic Auditorium in Grand Rapids, September 21-23. Physicians addressing the general sessions by invitation include:

Dallas B. Phemister, Chicago, Treatment of Osteomyelitis as Modified by Antibiotic and Chemotherapy.
Arthur R. Colwell, Evanston, Ill., Types of Diabetes Mellitus and Their Management.
John S. Lundy, Rochester, Minn., The Anesthesiologist Is Prepared to Anesthetize the Surgical Patient, to Aid in Differential Diagnosis of Pain Paths and to Resuscitate the Patient.
Earl D. Osborne, Buffalo, Diagnosis and Treatment of Cutaneous Malignancy.
Warren E. Wheeler, Columbus, Ohio, Pulmonary Infections with Histoplasma in Children.
Edwin Davis, Omaha, Pitfalls in Urological Diagnosis.
Joseph L. Baer, Chicago, Prolonged Labor.
Arthur P. Stout, New York, Cancer of the Stomach.
John M. Waugh, Rochester, Minn., Surgical Management of Malignancy of the Ampullary Region.
Frederick H. Falls, Chicago, Early Diagnosis of Carcinoma of the Uterus.
Ralph J. McQuiston, Indianapolis, Deep Infections of the Neck.
Herbert C. Miller Jr., Kansas City, Kan., Effect of Prenatal Factors on Survival of Newborn Infants.
John E. Gordon, Boston, A New Principle in the Control of Communicable Diseases.
Robert M. Zollinger, Columbus, Ohio, Indications for Surgery in Gallbladder Disease.
Edward C. Reifenstein Jr., Syracuse, N. Y., Use of Steroid Hormones in Bone Disease of Aging People.
Ralph O. Rychener, Memphis, Tenn., Glaucoma in General Practice.
William J. Dieckmann, Chicago, Indications and Methods for Terminating Pregnancy in the Last Trimester.
Max Thorek, Chicago, Impending Death Under Anesthesia.
William B. Castle, Boston, Basic Principles in the Treatment of Blood Dyscrasias.
Joseph E. Moore, Baltimore, Recent Advances in the Study of Venereal Diseases.
Harry E. Bacon, Philadelphia, Diagnosis and Treatment of Common Diseases of the Anorectum.
Franklin G. Ebaugh, Denver, Iatrogenicity in Medicine.
Arnold S. Jackson, Madison, Wis., Acute Surgical Abdomen.
Robert L. Jackson, Iowa City, Importance of Breast Feeding.
Ursus V. Portmann, Cleveland, Cancer of the Breast.
Robert E. Gross, Boston, Surgical Treatment for Coarctation of the Aorta.
John P. Peters, New Haven, Conn., Causes and Treatment of Lower Nephron Nephrosis.

Section meetings will be held at noon. An added feature of the meeting will be the postsession "Cancer Day" scheduled for Saturday, September 24. Technical and scientific exhibits will be shown.

## MISSOURI

**State Board of Medical Examiners.**—At a recent meeting of the Missouri State Board of Medical Examiners the following members were selected to serve for one year: Drs. William O. Finney, Chaffee, president; Walter L. Brandon, Poplar Bluff, secretary-treasurer; Edwin C. White, Kansas City; Howard B. Goodrich, Hannibal, and Francis T. H'Doubler, Springfield.

## NEW YORK

**Personals.**—Dr. Harold Buckbee of Dolgeville was named president of the New York State Public Health Officers Organization at its annual meeting.——Dr. William Thalhimer, New York, has been appointed assistant pathologist and medical examiner at the department of laboratories and research of Westchester County located in Grasslands Hospital, Valhalla.

**Dr. Evans Appointed to State University.**—President Alvin C. Eurich, Ph.D., of the State University of New York on August 15 announced the appointment of Dr. Lester J. Evans as consultant in medical education to the state university. Dr. Evans, medical associate of the Commonwealth Fund, will assume his duties immediately and will continue with the Commonwealth Fund on a part time basis. He will assist in formulating plans for the establishment of the over-all university medical education program. Dr. Evans has been associated with the Commonwealth Fund program for twenty-six years, starting in 1923 as medical director of its child health demonstration activities in Fargo, N. D. Since 1928 he has been a member of the staff at its executive offices in New York City. In his early years with the fund Dr. Evans worked in the fields of preventive medicine, rural hospitalization and rural public health. More recently his primary concerns have been with the supervision of grants for medical education and research. He is a graduate of the School of Medicine of Washington University in St. Louis. He spent two years in graduate pediatric training at the St. Louis Children's Hospital before joining the Commonwealth Fund.

### New York City

**Offer Hospital Facilities for Study.**—Queens General Hospital is opening its wards and clinics to doctors of the county for teaching purposes. It is hoped that physicians who do not have hospital appointments will be the first to avail themselves of this opportunity for study. The plan was inaugurated July 6 at the regular monthly conference of the department of medicine. The schedule included clinics, conferences, seminars, lectures and demonstrations as well as formal war rounds. Dr. Arthur A. Fischl, president of the Medical Society of the County of Queens, stated that the medical society has long advocated such a relationship and has pledged active support of its graduate education committee.

**Dr. Most to Head Research in Tropical Medicine.**—Dr. Harry Most, associate professor of preventive medicine, has been appointed a full professor of preventive medicine at New York University College of Medicine, a unit of the New York University-Bellevue Medical Center, effective September 1. Dr. Most will continue to be in direct charge of the New York University-Bellevue Medical Center's expanding program of tropical medicine. He will be in charge of a tropical disease diagnostic clinic currently undergoing formation by the New York City Health Department in the Lower East Side District Health Center. Dr. Most, a member of the college faculty for the past ten years, is deputy chief consultant in tropical disease to the Veterans Administration and a member of the National Research Council's Committee on Tropical Disease. He is also consultant in tropical medicine to the surgeon general, U. S. Army, the commissioner of health, New York State, and the marine hospitals of the U. S. Public Health Service.

## NORTH CAROLINA

**Personal.**—Dr. Alfred T. Hamilton has been appointed chief prison surgeon succeeding Dr. Benjamin J. Lawrence, who has held the position for 12 years. Dr. Lawrence is resigning to devote more time to his own practice.

**Symposium on Medicine.**—The annual symposium of the Duke University School of Medicine, will be held at Durham October 13-15. The general subject will be the "Basis of Disease." Among the guest speakers will be Drs. Stanley E. Bradley, New York City; Daniel E. Clark, Chicago; John H. Dingle, Cleveland; Robert Elman, St. Louis; Paul Klemperer, New York; Joseph L. Lilienthal Jr., Baltimore; Cyril N. H. Long, New Haven, Conn.; William Parsons, Charlottesville, Va.; Hans Selye, Montreal, and Robert W. Wilkins, Boston.

## RHODE ISLAND

**Dr. Magill Named State's Chief Examiner.**—Dr. William H. Magill, Providence, has been appointed to the new post of chief medical examiner of the state. The new system under which twelve county medical examiners will be responsible for examining cases involving violent death or death in suspicious circumstances went into effect July 1. Under the old system there were thirty examiners and an associate examiner. Dr. Magill has been medical examiner in Providence for forty-three years. He personally is charged with performing all autopsies.

## TEXAS

**Gift to Establish Department of Physical Medicine.**—Baylor Hospital, Dallas, recently received a gift of $133,000 from Grady H. Vaughn, Dallas business man and patient at Baylor, to construct and equip a department of physical medicine. The new department will be located on the first floor of the hospital's new Truett Memorial Hospital Building, which is to be constructed.

**University Expands Teaching Facilities.**—Under provisions of a special appropriation by the legislature of the state of Texas, the University of Texas School of Medicine, Galveston, is admitting 162 students to the first year class this fall. Funds have been provided for necessary expansion of teaching facilities and personnel. A new laboratory building, being provided by funds from a special bond issue, will house the departments of bacteriology and parasitology; pharmacology; biochemistry and nutrition, and physiology. It will also provide facilities for an expanded library.

## WEST VIRGINIA

**State Medical Election.**—At the annual meeting of the West Virginia State Medical Association at White Sulphur Springs August 4-6, Dr. Russell B. Bailey of Wheeling was elected president; he will assume duties Jan. 1, 1950. Dr. T. Maxfield Barber, Charleston, was reelected secretary-treasurer for his twenty-third consecutive term. Dr. George F. Evans, Clarksburg, was chosen American Medical Association delegate from West Virginia succeeding Dr. Ivan Fawcett of Wheeling, who has served as one of the two delegates from the state since 1938. The next annual meeting will be held at White Sulphur Springs, July 27-29, 1950.

**Personals.**—Dr. Charles A. Zeller, medical director of the Governor Bacon Health Center, at Delaware City, Del., was appointed superintendent of Weston State Hospital late last spring. Doctor Zeller succeeded Dr. Joseph L. Knapp, who resigned to become associated with the Beverly Hills Sanitarium in Dallas, Texas. The new superintendent, a graduate of the University of Buffalo School of Medicine, has been active in the field of mental health in Delaware, Pennsylvania, Michigan and Indiana.——Dr. Newman H. Dyer of Charleston, state health commissioner, was elected president of the West Virginia University Alumni Association at the annual meeting in Morgantown during commencement exercises in June.——Dr. Walter E. Vest, Huntington, was elected president of the new West Virginia medical licensing board at its organization meeting held July 7 in Charleston.——Dr. James L. Patterson of Logan has been elected president of the West Virginia Chapter of the Medical College of Virginia Alumni Association, succeeding Dr. L. Rush Lambert of Fairmont.

**Survey for Prospective Medical School.**—Dr. Alan Gregg, director of medical science for the Rockefeller Foundation, and Dr. Herman G. Weiskotten, dean of Syracuse (N. Y.) University College of Medicine and chairman of the American Medical Association Council on Medical Education and Hospitals, have been asked to conduct separate surveys concerning the advisability of building and maintaining a four year school of medicine and dentistry in West Virginia. The request for the survey was made by the legislative interim committee in consultation with the citizens advisory committee set up by the 1949 legislature for the purpose of studying the whole medical school question. The meeting of the two groups on August 8 followed closely the state medical association's adopted resolution favoring the establishment of the school as a part of West Virginia University. The question of site for the proposed school was not raised by the state association or the two interim groups. The legislative interim committee will meet with the advisory committee when the proposed impartial surveys have been completed. The groups will submit a report to Governor Patteson prior to the next regular session of the legislature in January 1951.

## WYOMING

**State Medical Meeting.** — The Wyoming State Medical Society will hold its annual meeting September 12-14 at the Townsend Hotel in Casper, under the presidency of Dr. George E. Baker, Casper. Guest speakers include:

Claude F. Dixon, Rochester, Minn., Surgery of the Gallbladder.
Daniel R. Higbee, Denver, Case Selection in Treatment of Carcinoma of the Bladder.
L. Martin Hardy, Chicago, Congenital Abnormalities of the Upper Alimentary Tract.
John W. Huffman, Chicago, Postoperative Pulmonary Complications.
Earl E. Barth, Chicago, Roentgen Findings in Common Pulmonary Lesions.
Frederick W. Fitz, Chicago, Bacterial Pneumonia.
Edgar B. Johnwick, Hot Springs, Ark., Observations on Venereal Disease.

The Woman's Auxiliary will meet in conjunction with the state association.

## ALASKA

**Premarital Examinations.**—Beginning June 17 all applicants for marriage licenses in the Territory of Alaska are required to take a physical examination, including a standard serologic test for syphilis within 30 days before the marriage license is issued. In areas not having the services of a licensed physician an affidavit to that effect will be sufficient proof for a U. S. Commissioner to issue a marriage license.

## GENERAL

**Special Society Election.**—The Western Association of Industrial Physicians and Surgeons at its annual meeting in San Francisco chose the following officers: Drs. Rodney R. Beard, San Francisco, president; R. Christopher Leggo, Crockett, Calif., secretary, and John E. Kirkpatrick, San Francisco, treasurer.

**New Surgical Society.**—The Neurosurgical Society of America was founded June 5, 1948, and incorporated in the State of Illinois the following July. It was formed to stimulate fellowship among young neurosurgeons and to disseminate neurosurgical materials among the group. The requirements for membership must comply with requirements set up by the Board of Neurological Surgery. Officers include Drs. Arthur A. Morris, Washington, D. C., president; Edward R. Schlesinger, New York, secretary, and Irving J. Speigel, Chicago, treasurer. The second annual scientific meeting will be held at the Chateau Frontenac in Quebec October 17-19.

**Veterinarians Recommend Use of Pound Dogs for Research.**—Resolutions favoring the use of pound animals for medical research and training were passed by three veterinary groups in July. These would apply only to animals that would otherwise have been killed. The same resolution has now been passed by the Conference of Veterinary Physiologists and Pharmacologists, the Public Health Section of the American Veterinary Medical Association and the National Association of Federal Veterinarians. The mutually recommended resolution states in part: "Resolved, that dogs and cats that would otherwise be killed in public pounds be made available under suitable regulations for intelligent humane use in teaching and research laboratories."

**Research in Paraplegia.**—A program of laboratory and clinical research on paraplegia was announced in July by the National Paraplegia Foundation, which is sponsored by the Paralyzed Veterans of America. The foundation's work is aimed at the problems of civilian paraplegia; headquarters are in the LaSalle Hotel, Chicago. The first and most important step in the program, according to Gilford S. Moss, executive director of the foundation, is the establishment of fellowships to provide uninterrupted research in physiology and bacteriology. Other aims of the foundation are to draw public attention to the plight of the civilian paraplegic and to work toward his rehabilitation. According to Mr. Moss, there are 33 times more paraplegic civilians than paraplegic veterans in the country today.

**The Childs Memorial Fund.**—The Jane Coffin Childs Memorial Fund for Medical Research during the past year has made grants for support of cancer research projects and fellowship appointments totaling $92,435. Among the largest of the 22 grants are $10,000 to Dr. E. S. Guzman Barron for studies of the metabolism of blood cells and of blood-producing tissues in health and disease; $8,500 to Dr. Samuel C. Harvey, Yale University School of Medicine, New Haven, Conn., for clinical and laboratory studies of cancer; $8,000 to Dr. Eugene L. Opie, Rockefeller Institute for Medical Research, for studies on osmotic and cytologic effects of hepatic tumor-producing diets; $7,500 to Dr. Frances Duran-Reynals, Yale University School of Medicine, for the third year of his present grant for the study of the relation of viruses to tumors.

**Southwestern Surgical Congress.**—The first annual meeting of the Southwestern Surgical Congress will be held at the Shamrock Hotel, Houston, Texas, September 26-28, under the presidency of Dr. Walter G. Stuck, San Antonio, Texas. Physicians invited to speak include: Robert L. Sanders, Memphis, Tenn.; Benjamin T. Beasley, Atlanta, Ga.; Arthur H. Blakemore, New York; Robert M. Moore, Galveston, Texas; Murray M. Copeland, Washington, D. C.; Keith S. Grimson, Durham, N. C.; Francis C. Grant, Philadelphia; H. Earl Conwell, University, Ala.; J. Duffy Hancock, Louisville, Ky.; Karl A. Meyer, Chicago; Brien T. King, Seattle, and J. Dewey Bisgard, Omaha.

A registration fee of $10 will be charged those other than the founders. The society was formed early in 1949.

**Medical Aspects of Crime.**—The Medical Correctional Association, an affiliate of the American Prison Association, desires to contact professional personnel interested in or concerned with the medical aspects of crime. The membership in this association is confined to the following groups: (1) physicians employed in penal and correctional institutions or jails; (2) physicians, social welfare workers and special workers engaged in medical research work in penal correctional institutions and jails; (3) physicians, psychiatrists, psychologists, social workers and special workers engaged in medical research work in connection with (*a*) institutions or hospitals for the mentally ill, (*b*) mentally defective persons, (*c*) juvenile delinquents, (*d*) defective delinquents, (*e*) outpatient or behavior clinics dealing with any aspect of crime or its prevention, (*f*) criminal, juvenile and domestic relations courts, (*g*) parole, (*h*) probation, (*i*) public and private schools, colleges and universities and (*j*) federal, state, county and municipal public health organizations, and (4) any person who presents satisfactory evidence that he or she is engaged in research or an occupation in which the medical aspects of crime are acknowledged as important features. Officers of the association are Dr. Frank J. Curran, Charlottesville, Va., president, and Dr. Edward C. Rinck, Medical Center for Federal Prisoners, Springfield, Mo., secretary-treasurer. Annual dues of $1 should be sent to the secretary.

**Prevalence of Poliomyelitis.**—Reports of cases of poliomyelitis for the periods indicated have been received from the National Office of Vital Statistics, U. S. Public Health Service.

**Roentgen Ray Society Meeting.**—The annual meeting of the American Roentgen Ray Society will be held at the Netherland Plaza Hotel, Cincinnati, October 4-7, under the presidency of Dr. Lawrence Reynolds, Detroit. Physicians presenting papers by invitation include:

Robert M. Potter, Chicago, Aid to the Diagnosis of Polypoid Lesions of the Colon.

Charles A. Priviteri, Chamblee, Ga., Gastrointestinal Radiographic Observations of Patients Treated by Vagotomy.

James A. Helmsworth, Johnson McGuire and Benjamin Felson, Columbus, Ohio; Joseph E. Miller, Dallas, Texas; Charles T. Dotter, Israel Steinberg, Cranston W. Holman, New York; and C. Robert Hughes, Robert E. Wise, John R. Hannan, Cleveland, Clinical and Technical Problems in Angiography.

A symposium on thoracic disease has been arranged by the University of Cincinnati College of Medicine with faculty members invited to participate. Other invited speakers on the subject include Drs. John R. McDonald and Oscar T. Clagett, Rochester, Minn.; John A. Evans and Ted R. Smalldon, New York, and Eugene L. Saenger, Cincinnati. A similarly organized symposium has been arranged by Western Reserve University School of Medicine, Cleveland, on the application of radioactive isotopes. In addition to the invited faculty members, invitations have been extended to Dr. Bernard S. Wolf and R. Loevinger, Ph.D., New York; R. J. Kennedy, Ph.D., and W. Snyder, B.S., Washington, D. C.; Drs. Henry Quastler, Urbana, Ill.; Robert H. Coleman, Omaha, Neb., and R. Wayne Rundles, Durham, N. C. A third symposium will be presented by invited faculty members of Ohio State University College of Medicine, Columbus, on Combined Management of Hematologic and Allied Diseases from the Medical and Radiologic Viewpoints. The Caldwell Lecture will be delivered by Dr. Stanley P. Reimann Philadelphia, on "Differentiation of Cells and Tissues." He will receive the medal of the society. The annual banquet will take place Thursday at 7:30 p. m.

## LATIN AMERICA

**Dr. P. O. Wolff Joins WHO.**—Dr. Pablo O. Wolff, Buenos Aires, has been appointed medical officer at the headquarters of the World Health Organization in Geneva, Switzerland, effective July 25.

**Institute of Oncology.**—On grounds of the Ciudad University, the Liga Dominicana contra el Cancer, Trujillo City, District of Santo Domingo, on May 8 inaugurated its $95,000 Institute of Oncology, built with an initial endowment of $40,000 from Dr. Herbert Pieter, Trujillo City, and completed by public subscription. The hospital has a capacity of 80 beds and is equipped with radium offered by the Hon. President Trumillo Molina.

**Child Separation Study.**—A five year research study of the effects of separation of children from their mothers is being conducted by psychiatrists of Tavistock Clinic in London. More than 200 children are to be watched at home and in clinics. The research will be conducted at clinics in the North-West Metropolitan Hospital Region and at hostels.

## CORRECTION

**Coulee Dam Needs Two Doctors.**—The U. S. Bureau of Reclamation, which is seeking two doctors for the Coulee Dam area of Eastern Washington will contribute up to $1,500 toward the cost of remodeling an available building into offices as desired by the new tenants, not $15,000 as was stated in The Journal July 30, page 1108.

# Marriages

Clyde Vaughan Stanley Jr., Stanley Town, Va., to Miss Patricia Meighan in Birmingham, Ala., June 30.

John Long Thompson Jr., Montgomery, Ala., to Miss Ann Ruth Swift in Birmingham, June 28.

David John Stephenson, Denver, to Miss Barbara Loise Waugh in Hanover, N. H., June 25.

Guy Phillip Sharpe Jr., to Miss Julia Katherine Wright, both of Roanoke, Va., June 25.

Samuel B. Johnson, New Orleans, to Miss Peggy Boswell at Sanatorium, Miss., June 25.

James Daniel Hardy, Philadelphia, to Miss Louise Scott Sams at Decatur, Ga., July 1.

John May, Bennettsville, S. C., to Miss Betty Brown in Hemingway, June 30.

# Deaths

**Robert Sproul Carroll,** Asheville, N. C.; born in Cooperstown, Pa., Feb. 18, 1869; Marion-Sims College of Medicine, St. Louis, 1893; Rush Medical College, Chicago, 1897; fellow of the American Psychiatric Association, Association for the Study of Internal Secretions, Association for Research in Nervous and Mental Disease, Southern Society of Philosophy, American Association for the Advancement of Science, American Eugenics Society, American Ethnological Society, American Museum of Natural History and others; a founder and medical director of Dr. Carroll's Sanitarium, changed in 1912 to Highland Hospital, which he presented to Duke University at Durham in 1939 as a therapeutic unit in the department of psychiatry; in 1946 he retired as president and medical director; lecturer in psychiatry at Duke University; author of "The Mastery of Nervousness," 1917; "The Soul in Suffering," 1919; "Old at 40 or Young at 60," 1920; "The Grille Gate," 1922; "Aseptic Meningitis in Combating the Praecox Problem," 1923 and "What Price Alcohol?" 1941; died June 26, aged 80.

**Andrew Magee Harvey** ⊕ Long Beach, Calif.; born in Galesburg, Ill., Jan. 14, 1868; College of Physicians and Surgeons of Chicago, 1893; member of the House of Delegates of the American Medical Association in 1913, 1914 and 1916; emeritus member of the Illinois State Medical Society; member of the American Association of Industrial Physicians and Surgeons; fellow of the American College of Surgeons; served as assistant health officer and acting health officer; formerly practiced in Chicago, where he was chief physician and surgeon for the Crane Company; while residing in La Grange, Ill., he was president of the village board and the board of education; died July 18, aged 60.

**William Beverley Mason** ⊕ Washington, D. C.; born in 1874; Medical College of Virginia, Richmond, 1899; professor emeritus of otorhinolaryngology at George Washington University School of Medicine; specialist certified by the American Board of Otolaryngology; member of the American Laryngological, Rhinological and Otological Society and the American Otological Society; fellow of the American College of Surgeons; affiliated with the Episcopal Eye, Ear and Throat Hospital, where he served on the board, Children's Hospital, Columbia Hospital for Women and Lying-In Asylum, and Central Dispensary and Emergency Hospital; died June 30, aged 74, of coronary arteriosclerosis and duodenal ulcer.

**Wilhelm S. Anderson,** Northfield, Minn.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1903; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; served on the staffs of the Warren (Minn.) Hospital, Deaconess and St. Michael's hospitals in Grand Forks, N. D., and the U. S. Veterans Hospital in Fort Snelling; died June 26, aged 73, of coronary thrombosis.

**Hubert Rogers Arnold** ⊕ San Francisco; University of California Medical School, San Francisco, 1922; fellow of the American College of Surgeons; affiliated with St. Mary's Hospital; died June 20, aged 55, of cystic myeloma.

**Louis Axelrod** ⊕ Major, M. C., U. S. Army, Chicago; University of Illinois College of Medicine, Chicago, 1941; entered the regular U. S. Army in October 1942; served in Europe during World War II; recently assigned to Fitzsimmons General Hospital in Denver; killed near Idaho Springs, Colo., July 3, aged 32, in a skiing accident.

**Charles Edgar Barker** ⊕ Oklahoma City, Okla.; Denver and Gross College of Medicine, 1907; an Associate Fellow of the American Medical Association; fellow of the American College of Surgeons; one of the founders and formerly vice president Mercy Hospital, where he died June 3, aged 68, of cerebral hemorrhage.

**Percy Livingston Barnes,** Fort Steilacoom, Wash.; Pulte Medical College, Homeopathic, Cincinnati, 1905; formerly affiliated with Western State Hospital; died in Tacoma recently, aged 68.

**Frank Kelsey Belsley,** Benton Harbor, Mich.; Washington University School of Medicine, St. Louis, 1935; member of the American Medical Association; past president of the Berrien County Medical Society; affiliated with Mercy Hospital; died May 31, aged 40.

**Edward Weston Benham,** Mankato, Minn.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1895; died in Compton, Calif., June 19, aged 81, of cerebral arteriosclerosis and generalized arteriosclerosis.

**Pauline Bertram,** Keokuk, Iowa; College of Physicians and Surgeons, Keokuk, 1890; died May 8, aged 83, of cerebral hemorrhage.

**Isabel Mary Geddes Bridges,** Orlando, Fla.; Woman's Medical College of the New York Infirmary for Women and Children, New York, 1898; died April 6.

**Lionel Botleman Brown** ⊕ Stratton, Neb.; University of Nebraska College of Medicine, Omaha, 1922; served on the village board and board of health; affiliated with Stewart Hospital; died June 21, aged 53, of cerebral hemorrhage.

**Paul Edgar Conrad** ⊕ Hiawatha, Kan.; University of Nebraska College of Medicine, Omaha, 1924; killed May 20, aged 53, in an airplane crash.

**Charles B. Davis,** Walker, Mo.; Louisville (Ky.) Medical College, 1893; member of the American Medical Association; past president of the Vernon-Cedar Counties Medical Society; died June 15, aged 81, of cerebral thrombosis.

**Rutherford Scott Duemler,** Seneca, Mo.; University of Kansas School of Medicine, Kansas City, 1940; member of the American Medical Association; died in Freeman Hospital, Joplin, May 7, aged 38, of calculus of both kidneys.

**Samuel Ernest Edmunds,** Charleroi, Pa.; Atlantic Medical College, Baltimore, 1910; died June 8, aged 74, of carcinoma of the rectum.

**Raymond Clair Fagley,** Upper Darby, Pa.; Medico-Chirurgical College of Philadelphia, 1911; member of the American Medical Association, Missouri State Medical Association and the American Psychiatric Association; specialist certified by the American Board of Psychiatry and Neurology, Inc.; served during World Wars I and II; formerly chief medical officer of the regional office, Veterans Administration and senior physician at the Veterans Administration Hospital in Lyons, N. J., died in Kirklyn, May 28, aged 61.

**Samuel H. Greene Jr.,** Washington, D. C.; Columbian University Medical Department, Washington, 1900; member of the American Medical Association; died July 8, aged 75.

**Perley Harriman,** Kittery, Maine; University of Vermont College of Medicine, Burlington, 1902; member of the American Medical Association and the Massachusetts Medical Society; formerly practiced in Lynn, Mass., where he was affiliated with Union Hospital, where he died June 17, aged 81, of arteriosclerosis and endocarditis.

**Frederick Sears Hawes,** Russell, Kan.; Gross Medical College, Denver, 1902; served on the Kansas State Board of Registration and Examination; died June 14, aged 76, of carcinoma of the throat.

**William Albert Hinckle,** Peoria, Ill.; Hahnemann Medical College and Hospital, Chicago, 1903; member of the American Medical Association; past president of the Peoria County Medical Society; served during World War I; died in St. Francis Hospital July 3, aged 73.

**Francis Leslie Hoffman,** Sonoma, Mich.; University of Michigan Homeopathic Medical School, Ann Arbor, 1893; died May 28, aged 87.

**Benjamin Yeager Jaudon** ⊕ University City, Mo.; Columbia University College of Physicians and Surgeons, New York, 1896; an Associate Fellow of the American Medical Association; at one time medical director of the Missouri State Life Insurance Company in St. Louis; affiliated with Barnes Hospital, St. Louis, where he died July 1, aged 75, of coronary thrombosis.

**James M. McCabe,** Sun Prairie, Wis.; Milwaukee Medical College, 1908; member of the American Medical Association; died in Columbus May 11, aged 79, of carcinoma of the prostate.

**John M. Robinson,** Goshen, N. Y.; University of Pennsylvania Department of Medicine, Philadelphia, 1891; specialist certified by the American Board of Ophthalmology; member of the American Academy of Ophthalmology and Otolaryngology and the Minnesota State Medical Association; formerly on the staffs of St. Luke's and St. Mary's hospitals in Duluth, Minn.; died June 24, aged 79, of chronic myocarditis and cerebral hemorrhage.

**William C. Russwurm** ⊕ Helena, Ark.; Louisville (Ky.) Medical College, 1884; Medical Department of Tulane University of Louisiana, New Orleans, 1890; an Associate Fellow of the American Medical Association; past president of the Phillips County Medical Society; died June 9, aged 88, of coronary thrombosis.

**Guy Edward Stewart** ⊕ Fayette, Ala.; Medical College of Alabama, Mobile, 1904; served during World War I; died June 17, aged 68, of coronary thrombosis.

# Bureau of Investigation

## KOCH'S ADVERTISING TAKES ON A RELIGIOUS FLAVOR

William F. Koch, M.D., of Detroit, has a new angle in the propaganda for his "specific for cancer," frequently mentioned in THE JOURNAL since 1921.[1] He is now using a booklet, "The Birth of a Science," which is sold by mail from Wichita, Kansas, by the Defender Book and Bible House, and published by the Lutheran Research Society, Inc., Detroit.

"The Birth of a Science" describes Koch as "the modern Pasteur." Of him it also says:

> "Dr. William Frederick Koch, the man used by a kind and beneficent Providence to give new knowledge to the world for the relief of human suffering, consented to answer questions propounded by the authors. This provided a rich fund of information upon which to draw and enabled them to fill in many details which might have been otherwise lacking."

The booklet attacks organized medicine generally and the editor of THE JOURNAL in particular. Abstracts of testimony of "cures" taken from the proceedings in federal court wherein Koch was prosecuted for violation of the Federal Food, Drug and Cosmetic Act are quoted. Included, also, are the testimonials of osteopaths and a few Doctors of Medicine who have used Koch's injections. (The case mentioned ended in dismissal of the charges in 1948. Two trials, each lasting more than four months, the first in 1943 and the second in 1946, were indecisive. The first jury disagreed, but a member of the second became ill after the case had been heard and referred to the jury. Government attorneys moved for dismissal of the case, rather than try the same set of facts after so long a period had elapsed.) The recital of cures of tuberculosis, cancer, poliomyelitis and "pus infections" is similar to that usually employed by quacks.

The Lutheran Research Society, Inc., of Detroit also publishes a magazine, "The Eleventh Hour." Printed are articles attacking organized medicine, Communism and Jews. The publication hails Koch as a medical martyr and lately sympathizes with the promoters of the now defunct Kaadt Diabetic Institute at South Whitley, Ind.[2] (One of the Kaadt brothers is in a federal prison, the other too ill to begin his term.) At first glance, the "Society" seems to be an organization sponsored by the Lutheran church. The director is one Lawrence F. Reilly, who appears to have been educated for the ministry.

In 1948 Koch advertised his "specific" with a reprint of an excerpt from the *Congressional Record* for June 7, 1948, which was distributed, postage free, throughout the country under the frank of Senator Langer of North Dakota. The senator had obtained unanimous consent to the reading into the *Record* of an article alleged to have appeared in "The Eleventh Hour," reporting successful use of Koch's medication on dairy cattle in Canada. The facts were reported in THE JOURNAL for Aug. 7, 1948, page 1333.

To sell his "specific," Koch no longer has his "Koch Laboratories." Now it is the "Christian Medical Research League" of Detroit. This is a "nonprofit" corporation of Michigan. The articles of incorporation, filed in November 1948, show the purposes of the organization as:

> "Research in and development of drugs of a various nature including bio chemical oxidation catalysts, establishment of clinics for research in and mitigation of diseases, and for the training of personnel in the use of bio chemical oxidation catalysts, distribution of drugs and medicines to medical missionaries, manufacture, distribution and sale of drugs and medicines, the conduct of any legitimate business activity that will promote the foregoing or provide funds for the same."

The incorporators are two ministers, the Rev. William T. Watson, D.D., of St. Petersburg, Fla., and the Rev. Sam Swain, D.D., of Akron, Ohio, and a layman, Laurence B. Thatcher of Imlay City, Mich., said to be a dealer in tombstones!

The Rev. Sam Swain is described in the files of the Bureau as:

> ". . . an ordained minister of the gospel, and his denomination is Evangelical United Brethren . . . He has a bookstore . . . and conducts forums and discussion groups, bringing in outside speakers. His organization is known locally as the National Gospel Center, which is a store-front building on South Broadway in Akron."

The same source reveals that Swain is "on the fringe of quackery in religion and an out-and-out fascist. He is not a member of the Akron Ministerial Association, but is classed by this body as an itinerant evangelistic minister with a low rating of respectability in the community." A fellow minister indicated that he was ashamed that Swain was an ordained minister of his denomination.

The Rev. William T. Watson is said to be the minister of "The Tabernacle" in St. Petersburg, which is not associated with any conference or regular church organization. The facts with respect to his religious training or ordination are not clear, and his sermons are described as being of the "hellfire-and-brimstone" type.

The Defender Book and Bible House is an enterprise of Gerald B. Winrod, one of the defendants in the long-drawn-out trial for subversive activities in Washington, D. C. Government prosecutors proceeded on the basis that Winrod was a Nazi worker; the newspaper stories on his divorce case a few years ago indicated that his wife gave some sensational testimony along the same line. Winrod is described as being a controversial figure and as a preacher with considerable oratorical ability, but he is not known to be connected with any particular religious denomination. Rather, he appears to be in the printing business. He is said to possess an extensive and well equipped printing plant in Wichita, which might account in some manner for his espousal of the Koch propaganda.

Religion and religious beliefs have long been used by quacks and faddists as a smoke-screen for their nefarious activities. Faith healers and cultists have found it profitable to utilize man's craving for mysticism. Some probably have been sincere. The more spectacularly successful, however, have seen the business possibilities and have played the game for all it was worth. One writer,[3] commenting on this tendency in quacks, observed:

> "No Quack is a perfect Quack without a pretense of religion. Deprive him of religion and you deprive him of his strongest sales talk. In that respect the Quack differs from the Bootlegger, Poacher and Abortionist. Religion is not regulated by law, until it interferes with the rights of the public . . ."

Again he comments, "Apparently no quack has conscience enough to prevent him from hiding behind religion."

Of the need for physical means to further the acceptance of the healers' doctrines, he wrote:

> "Healing by Faith has always its limitations. The patient must have a keen sense of perception—or a keen sense of imagination—to be healed. To overcome any lack of imagination, faith healers usually use some other agency like stump water, boiling a nail in the milk you drink, or carrying a rabbit's foot; on the same principle that physicians sometimes use a 'placebo' or dough pill to impress the patient. A. T. Still's 'placebo' was 'adjusting the spine,' which is just about as effective as trying to warm your feet in the moonlight. Rubbing the back is an old idea, nearly all tribes and races have tried it. Only America has glorified it and made it a system of healing."

Koch, of course, has always had his "Glyoxylide." Now he has the religious approach; he has learned, apparently, that people regard religion with respect and are not apt to question statements made by ministers or priests because of faith in their honesty and sincerity of purpose.

The facts with respect to Lutheran Research Society sponsorship are revealing. Of the Lutheran Research Society, the Division of Public Relations of the National Lutheran Council and the Lutheran Church-Missouri Synod recently released for publication the following statement:

> "The Lutheran Research Society of Detroit was disavowed in a joint statement issued here by the National Lutheran Council and the Lutheran Church–Missouri Synod, which represent virtually all the Lutheran groups in America.
>
> "The Society, which has been accused of promoting anti-Semitic propaganda through its periodical, 'The Eleventh Hour,'

A. **76:** 466 and 537 (Feb. 12 and 19) 1921; **82:** 2054 (June 21) 1924; **86:** 1469 (May 8) 1926; **88:** 928 (March 19) 1927; **103:** 116 (July 14) 1934; **106:** 929 (March 14) 1936; **107:** 519 and 1405 (Aug. 15 and Oct. 24) 1936; **112:** 1460 (April 15) 1939; **113:** 711 (Aug. 19) 1939; **116:** 2525 (May 31) 1941; **117:** 216 (July 19) 1941; **118:** 734 and 1373 (Feb. 28 and April 18) 1942; **119:** 502 (June 6) 1942; **121:** 691 (Feb. 27) 1943; **122:** 389 (June 5) 1943; **130:** 1040 (April 13) 1946; **137:** 1333 (Aug. 7) 1948.

[2] J. A. M. A. **137:** 402 (May 22) 1948.

[3] Warner, C. W.: Quacks, Jackson, Miss., The Author, 1930.

and other publications, 'is not sponsored or officially connected with any of the Lutheran church bodies in this country,' the statement said.

"It added that the eight participating bodies of the National Lutheran Council, and the Lutheran Church-Missouri Synod, 'have had no connection with the Lutheran Research Society and have espoused no part of its program.'

"The Lutheran Research Society has, through its publications and otherwise, promoted an alleged cancer remedy and other drugs formerly distributed by Dr. William F. Koch of Detroit, Michigan, which drugs have been questioned by the United States Government, according to counsel. These drugs are currently distributed by an organization known as the Christian Medical Research League. The latter organization is likewise in no way affiliated with any of the Lutheran bodies in America.

"The statement said further that Lawrence F. Reilly, who organized the Lutheran Research Society in 1946, and is its executive director, is not a member of the ministerium of any of the Lutheran bodies in America. All ordained clergymen in the Lutheran Church hold such membership."

The "not-for-profit" activities of the Christian Medical Research League of Detroit are similarly suspect as to their religious character. The Michigan authorities who gave the outfit its charter might well consider the revealing nature of the following item, which appeared on a letterhead of Koch:

"Since Dr. Koch wrote to you in May of 1948, he has turned over the manufacture and distribution of his treatment to the Christian Medical Research League, 14344 East Jefferson Avenue, Detroit, Zone #15. They are selling it only on prescription."

This pseudoreligious promotion in order to get business has resulted in considerable current interest in Koch's treatment. There are Lutheran ministers who have fallen for this line, and some others who may be made of the cloth that produces quacks. For instance, there is one in a small town near Chicago who has urged some of his parishioners suffering from cancer to come to Chicago to be treated by George Franklin Smith, one of Koch's disciples. Smith surrendered his Indiana license to practice medicine in 1948, rather than face charges of gross immorality in the practice of medicine preferred against him by the Indiana State Board of Medical Registration and Examination. He gave these victims, some of whom borrowed the money, the Koch injection. There is indication that one of his patients is still alive, but that case was never proved pathologically to have been of cancer. The pastor has his name on the letterhead of the Christian Medical Research League. He is now said to be urging the epileptic persons of his parish to take a mail-order treatment for epilepsy put out by the Western Medical Corporation of Chicago.

Koch has had thirty years in which to demonstrate the merits of his "specific for cancer." It would seem that by now the world would be beating a path to his door and he could take his place as a great servant of his fellow man by reason of his ability to conquer disease by such an elementary method. Competent medical investigation of his methods has been accorded him. That his claim of discovery of a specific for cancer so long ago is without any foundation of fact is borne out by events which have followed. His treatment is now administered, for the most part, by osteopaths, who may or may not be authorized under the various practice acts to use drugs. He has sold his nostrum to chiropractors, thus aiding the violation of law.[4] These cults have a religious flavor in their background, and so perhaps it is only natural that Koch would follow the line.

On the other hand, a practical problem may have presented itself here. Normal advertising channels are barred to Koch, by reason of the injunction granted against him to the Federal Trade Commission,[5] the government agency having jurisdiction over advertising in the drug field. No longer does he dare to claim therapeutic merit for his product, on the trade package or in the accompanying literature. No doubt he would find himself once more in difficulty with the Federal Food and Drug officials.

The religious approach in the exploitation of a product, which government chemists testified as being undistinguishable from distilled water,[6] as a "specific for cancer" is neither original nor scientific. The "birth of a science" has turned out to be an abortion.

# Medical Examinations and Licensure

## COMING EXAMINATIONS AND MEETINGS

### NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: *Parts I and II.* Various Centers. Sept. 12-14. Exec. Sec., Mr. E. S. Elwood, 225 S. 15th St., Philadelphia 2.

### EXAMINING BOARDS IN SPECIALTIES

American Board of Anesthesiology, Inc. *Oral.* Denver, Oct. 16-20. Sec., Dr. Curtiss B. Hickcox, 745 Fifth Ave., New York 27.

American Board of Dermatology and Syphilology, Inc.: *Written.* Various Centers, Sept. 15. *Oral.* Cincinnati, Oct. 21-23. Sec., Dr. George M. Lewis, 66 East 66th St., New York 21.

American Board of Internal Medicine: *Written.* Oct. 17. Asst Sec.-Treas. Dr. W. A. Werrell, 1 Main St., Madison 3, Wis.

American Board of Neurological Surgery: *Oral.* Chicago, June 3. Final date for filing applications is Jan. 1. Sec., Dr. W. J. German, 789 Howard Ave., New Haven.

American Board of Obstetrics and Gynecology, Inc. *Part I.* Various Centers. Feb. 3. *Final* date for filing application is Nov. 5. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh.

American Board of Ophthalmology: St. Louis, Oct. 15-19; Boston, April. Sec., Dr. Edwin B. Dunphy, 56 Ivie Rd., Cape Cottage, Maine.

American Board of Orthopaedic Surgery. *Part II*, New York City, Feb. 9-10. Address: Sec.-Treas., Dr. Harold A. Sofield, Room 1856, 122 S. Michigan Ave., Chicago.

American Board of Otolaryngology: Chicago, Oct. 4-7. Sec., Dr. D. M. Lierle, University Hospitals, Iowa City.

American Board of Pathology: Chicago, Oct. 7-8. Final date for filing application is Sept. 1. Sec., Dr. Robert A. Moore, 507 Euclid Ave., St. Louis.

American Board of Pediatrics: *Oral.* Cleveland, Sept. 16-18; New York City, Oct. 21-23; Chicago, Dec. 9-11. Sec., Dr. John McK. Mitchell, 6 Cushman Road, Rosemont, Pa.

American Board of Plastic Surgery: Examinations are given in June and November *of each year in the home town of applicants.* Sec.-Treas., Dr. Louis T. Byars, 400 Metropolitan Bldg., St. Louis, Mo.

American Board of Preventive Medicine and Public Health: *Parts I and II.* New York, Oct. 22-24. Sec., Dr. Ernest L. Stebbins, 615 N. Wolfe St., Baltimore.

American Board of Proctology: November. Sec., Dr. Louis A. Buie, 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Psychiatry and Neurology, Inc. *Special Examination.* Chicago, Oct. 24-25. December, New York City. Final date for filing applications is Sept. 15. Sec., Dr. F. J. Braceland, 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Radiology: *Oral.* Cincinnati, Sept. 28-Oct. 2. Sec., Dr. B. R. Kirklin, 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Surgery: *Written.* Various Centers, October 26. Sec., Dr. J. Stewart Rodman, 225 S. 15th St., Philadelphia.

American Board of Urology: *Written.* December. *Oral and Clinical.* Chicago, Feb. 11-15. Final date for receipt of case histories is Sept. 1, 1949. Sec., Dr. Harry Culver, 7935 Sunnyside Road, Minneapolis 18.

### BOARDS OF MEDICAL EXAMINERS

Alaska:* Juneau, Sept. 6. Sec., Dr. W. M. Whitehead, Box 140, Juneau.

Alabama: *Examination.* Montgomery, June 27-29. Sec., Dr. D. G. Gill, 519 Dexter Avenue, Montgomery.

Arkansas:* *Examination.* Little Rock, Nov. 3-4. Sec., Dr. Joe Verser, Harrisburg. *Eclectic.* Little Rock, Nov. 3. Sec., Dr. Clarence H. Young, 1415 Main St., Little Rock.

District of Columbia:* *Examination.* Washington, Nov. 14-15. Sec., Dr. G. C. Ruhland, 4130 E. Municipal Bldg., Washington.

Florida: *Examination.* Jacksonville, Nov. 27-29. Sec., Dr. Frank D. Gray, 12 N. Rosalind Ave., Orlando.

Georgia: *Examination.* Atlanta, Oct. 11-12. *Reciprocity.* Atlanta, Oct. 13. Sec., Mr. R. C. Coleman, 111 State Capitol, Atlanta 3.

Guam: *Endorsement.* Agana, Last Friday of each month. Sec., Capt. C. K. Youngkin, Dept. of Public Health, Guam, % F.P.O., San Francisco.

Illinois: Chicago, Oct. 4-6. Supt. of Registration, Mr. Fred W. Ruegg, Capitol Bldg., Springfield.

Indiana: *Examination.* Indianapolis, June. Sec., Dr. Paul R. Tindall, 1138 K. of P. Bldg., Indianapolis.

Iowa: *Examination.* Des Moines, Dec. 5-7. *Reciprocity.* Des Moines, Sept. 5, Oct. 3, Nov. 7, Dec. 5. Sec., Dr. M. A. Royal, 506 Fleming Bldg., Des Moines.

Kansas: Topeka, Dec. 8-9. Sec., Dr. J. F. Hassig, 905 N. Seventh St., Kansas City.

Maryland: *Examination.* Baltimore, Dec. 13-16. Sec., Dr. Lewis P. Gundry, 1215 Cathedral St., Baltimore 1. *Homeopathic. Examination.* Baltimore, Dec. 13-14. Sec., Dr. John A. Evans, 612 West 40th St., Baltimore.

Minnesota:* Oct. 18-19. Sec., Dr. Julian F. Du Bois, 230 Lowry Medical Arts Bldg., St. Paul 2.

Mississippi: *Reciprocity.* Jackson, December. Sec., Dr. Felix J. Underwood, State Board of Health, Jackson 113.

Missouri: *Examination.* Jefferson City, October 24-26. *Reciprocity.* Jefferson City, October, 23. Exec. Sec., Mr. John A. Hailey, State Capitol Building, Jefferson City.

Montana: Helena, Oct. 3-5. Sec., Dr. Otto G. Klein, First National Bank Bldg., Helena.

Nevada: Carson City, Nov. 7. Sec., Dr. George H. Ross, 112 N. Curry St., Carson City.

New Hampshire: Concord, Sept. 8-9. Sec., Dr. J. S. Wheeler, 107 State House, Concord.

New Jersey: Oct. 18-21. Sec., Dr. E. S. Hallinger, 28 W. State St., Trenton.

New Mexico:* Santa Fe, Oct. 10-11. Sec., Dr. Charles J. McGoey, Coronado Bldg., Santa Fe.

New York: *Examination.* New York, Albany, Syracuse and Buffalo, Oct. 4-7. Sec., Dr. Jacob L. Lochner Jr., 23 S. Pearl St., Albany 7.

North Carolina: *Endorsement.* Asheville, Oct. 17. Sec., Dr. Ivan Proctor, 226 Hillsboro Street, Raleigh.

Ohio: *Examination.* Columbus, December. *Endorsement.* Oct. 2. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

Puerto Rico: San Juan, Sept. 6-10. Sec., Dr. Luis Cueto Coll, Box 3717, Santurce.

South Carolina: *Examination.* Columbia, Nov. 8-9. *Reciprocity.* First Monday of every month. Sec., Dr. N. B. Heyward, 1329 Blanding St., Columbia.

Tennessee: *Examination.* Memphis, Sept. 28-29. Sec., Dr. H. W. Qualls, 1635 Exchange Bldg., Memphis 3.

Virginia: *Examination.* Richmond, Dec. 2-3. *Reciprocity.* Richmond, Dec. 1. Sec., Dr. K. D. Graves, 631 First St., S.W., Roanoke.

Wisconsin: * *Examination.* Madison, Jan. 10-12. Sec., Dr. C. A. Dawson, River Falls.

Wyoming: Cheyenne, Oct. 3. Sec., Dr. Franklin D. Yoder, Capitol Bldg., Cheyenne.

## MEDICOLEGAL ABSTRACTS

**Malpractice: Physician's Failure to Use Sterile Instruments.**—This was an action for damages for personal injuries resulting from the alleged negligence of the defendant physician. From a judgment in favor of the physician, the plaintiff appealed to the district court of appeal, second district, division 3, California.

The plaintiff, a man 41 years of age, went to the defendant's office on June 7, 1944, for a cystoscopic examination. After giving the doctor a history he was taken to another room for further tests and examinations preparatory to the cystoscopic examination. The table in the cystoscopic examination room on which the plaintiff was placed was so constructed that the patient could be turned from a prone position to an erect position without being removed therefrom. While on the table the plaintiff could not see and did not know what was being done except what he could feel. A layman, called a technician, prepared him for examination. From a nurse in the next room the technician obtained a tray containing an installator, swab, water tube, two syringes, a peroneal towel and a sheet. He washed the plaintiff's male organ, injected an anesthetic therein and inserted a ¼ inch stopper to hold the anesthetic in place. The defendant, with a cystoscope taken from a tray in another room, then entered the examination room. A cystoscope is an instrument about twice the length of a fountain pen, but smaller in diameter, made of nickel-plated copper, with the end turned up and a hollow shaft through the center. It was lubricated with a nonoily lubricant. The technician removed the stopper, and the defendant introduced the cystoscope into the opening, inserted it through the organ into the bladder and observed the interior of the bladder, which appeared normal in every respect. Catheters were then inserted through the cystoscope into the bladder through both renal pelves and pushed through the ureter to the kidneys. The catheters had been threaded into the cystoscope by someone not named in the evidence. A specimen of urine was collected through the catheters into test tubes, and examination showed no bacteria or pus. A dye solution was injected into each urethral catheter and roentgenograms taken while the plaintiff was in prone and standing positions and while the instruments remained in his body. The catheters were then withdrawn; the solution remaining in the ureter was allowed to trail to the bladder as far as the prostate level, and roentgenograms were taken. All roentgenograms were normal. At the trial, the defendant testified that fever which develops an unusual time after a cystoscopic examination is not the normal reaction therefrom, and he told the plaintiff that if any reaction occurred at all it would occur within two hours. He also told him that the results of the examination were entirely normal, that the blood cell count, hemoglobin, heart, pulse rate and respirations were normal, that his prostate, prostatic secretion and urine were normal, that his prostate was normal in size, shape and consistency, that his bladder was normal, that both his prostate and bladder showed no pathologic condition, that his kidneys and ureters were normal and that he was a textbook picture of perfection.

About twenty-four hours later the plaintiff began feeling odd. He had chills and fever all that night and all the next day. On June 10 he received some medicines from the defendant's office which he understood were sulfonamide drugs, which he started taking in the afternoon, but he continued having chills and fever that day and all the next day, when he was taken to a hospital. The fever and chills persisted until June 14, and he remained in the hospital until June 16. While in the hospital the plaintiff was attended by an assistant of the defendant. The plaintiff asked this assistant what was causing his severe chills and high temperature, and the assistant replied, "That's hard to say. Everyone knows you have an acute infection of the urinary passages, but I can't understand how it got there. But that is why you are being given the sulfa drugs and pyridium. These medicines are for infections of that kind." About a week later, when the plaintiff was able to leave his home for the first time, he went to the defendant's office. He was given a prostatic massage by the defendant's assistant and samples of his urine were taken for tests. After the tests were completed, he asked the assistant as to the results and was told that they showed that he still had a "25 per cent infection." He was given prostatic massages for the next month and on each occasion the defendant's assistant told him that he had an infection present in the urinary tract but that the amount was gradually decreasing, so that at the time of his last visit the test showed only 10 per cent. Sometime after June 23, while the defendant's assistant was giving the plaintiff a prostatic massage, the defendant appeared and the plaintiff said, "Dr. Belt, Dr. Guth just told me that I still have 10 per cent infection present. I didn't have any infection when I came in here in June and I don't see why I should have any now." The defendant replied that 10 per cent was within normal limits. The plaintiff then asked the defendant what had caused the infection in the urinary tract and the severe chills and high temperature, and the defendant replied, "To tell the truth, I don't know." An expert witness called by the plaintiff testified that the twenty-four hours between the time of the examination and the time the plaintiff began to have chills and fever probably was an incubation period for bacteria introduced into the urinary tract in the preparation for or in the making of the examination, that the introduction was evidently due to some defective condition of the instruments or carrying in from the opening of the meatus (the canal in the male organ), the edges of which were not thoroughly cleansed, and that the treatment given in the hospital was for an infection of the urinary tract. As we read the record, said the court, there is no evidence that either the stopper or the cystoscope or the catheters used in the examination were sterilized before insertion into the plaintiff's body. Neither the technician nor the defendant sterilized any one of them or saw any one of them sterilized. They assumed that they had been sterilized. No one testified that he sterilized any one of them. On the other hand, the court acknowledged, there is no direct evidence that they were not sterilized.

The plaintiff argued, in substance, that he had no infection at the time of the examination, which disclosed his genitourinary system to be in a healthy and normal condition; that an infection developed confined to the genitourinary system about twenty-four hours after the defendant's examination; that this infection must have been introduced during the examination by a failure of the defendant or his associates or employees to effect and maintain proper sterilization for the examination, and that an inference of negligence was therefore raised under the doctrine of res ipsa loquitur.

With this evidence before the jury, the trial court at the request of the defendant gave the following instructions: (1) "Negligence on the part of a physician is never to be presumed, and in the absence of expert testimony to the contrary, it is to be presumed that a physician possesses and has exercised the requisite degree of skill and care in examining a patient." (2) "In determining the question of whether the defendant was guilty of negligence as alleged in the complaint you cannot and must not set up a standard of your own but must be governed in that regard solely by the testimony of expert witnesses who have appeared and testified in this case." Under these instructions, said the court of appeals, the jury was not permitted to determine for itself that failure to properly sterilize the instruments inserted into the plaintiff's body or failure to properly sterilize the parts of the body through which the instruments were inserted, or both, was negligence. Failure on the part of a physician in either of these respects, the court continued, is negligence as a matter of common knowledge. There is no law, as applied to the facts of this case, which requires that the jury in determining those questions be governed solely by the testimony of expert witnesses. The practical effect of these instructions was to direct the jury to return a verdict for the defendant. The court of appeals concluded that an instruction is prejudicially erroneous which excludes an issue that is supported by evidence.

Furthermore, the trial court refused to give the following instruction requested by the plaintiff: "When it is common knowledge that an event or a circumstance that has happened to or developed in a patient is of the kind that ordinarily does not occur in the absence of negligence on the part of the physician attending him, the question whether or not the condition was caused by negligence may be decided from the general circumstances as shown by the evidence and in the light of common experience and reason." It is well settled, said the court, that in undertaking a treatment of a patient the practitioner impliedly contracts and represent not only that he possesses the reasonable degree of skill and learning possessed by others of his profession in the locality but that he will use reasonable and ordinary care and skill in the application of such knowledge to accomplish the purpose for which he is employed and that, if injury is caused by a want of such skill or care on his part, he is liable for the consequences which follow. The plaintiff, said the court, does not contend that the defendant did not have the requisite knowledge and skill. His contention is that the defendant was negligent in preparing for and making the examination, that there was no proper sterilization. Where the evidence conflicts, said the court, each party is entitled to have the law given to the jury which is applicable to his theory of the case and the testimony of his witnesses. The evidence in this case, the court of appeals concluded, without the testimony of experts, was sufficient to warrant the jury in finding that the infection was caused by the negligence of the defendant. It was, therefore, prejudicial error to give the two instructions requested by the defendant but to refuse to give the instruction requested by the plaintiff.

[In a dissenting opinion one of the judges said: "The majority opinion essentially holds that the appearance of an infection after surgery warrants an inference that the surgeon was negligent. I cannot agree. I doubt that my associates realize to what strange ends the doctrine they announce would lead. It is trite to say that examination and treatment by the insertion of instruments into or through the natural openings of the body, or through wounds, is a necessary part of the practice of medicine and surgery. It is also elementary that infection is an insidious and dreaded enemy and that great precautions are taken to prevent it. If it appears where a laceration has been repaired or a fracture reduced, or a tonsil removed or a throat or sinus examined or treated, is this a good reason for inferring negligence? If a patient has a sore throat after having his temperature taken, is it to be inferred that the thermometer was unsterile? If so, the practice of medicine and surgery would be a mixed profession and insurance business. A malpractice action would be little more than an order to the defendant to show cause why he should not pay damages. But I find no precedent for the theory on which the majority opinion proceeds. Laymen have never been allowed to say in a malpractice action that there was negligence because, in their opinion, a better result would probably have been reached if there had been no negligence."]

The judgment in favor of the defendant physician was reversed.—*Moore v. Belt, 203 P. (2d) 22 (Calif., 1949).*

**Workmen's Compensation Acts: Employees Refusal to Undergo Operation for Repair of Ruptured Intervertebral Disk.**—This was a claim for a compensation award for injuries arising out of and in the course of the claimant's employment with the K. Lee Williams Theatres, Inc., as a result of which accident the claimant sustained a fractured intervertebral disk. From the granting of an award of total permanent disability and the claimant's subsequent refusal to undergo a proffered operation for the repair of the fracture, the employer filed an original proceeding for review in the Supreme Court of Oklahoma.

About three months after the original compensation award had been allowed to the claimant, the employer filed a motion with the Industrial Commission asking that the Commission discontinue the payments of temporary total compensation on the ground and for the reason that the claimant's injury could be successfully operated on, that the operation had been tendered to the claimant but that he had refused to undergo it. The claimant replied that the operation offered was a major operation and that he could not legally be required to submit to it. The principal question, said the Supreme Court, is whether the refusal of the claimant to submit to a surgical operation will permit the employer to discontinue compensation payments.

There is much medical testimony in the record, said the Supreme Court. Some four or five physicians and surgeons testified. They all agreed that the claimant's disability is total and likely to be permanent unless an operation is performed, and they all recommended an operation, except one witness who testified that he would not recommend an operation without further hospitalization and while the claimant maintained the mental attitude toward the operation which he had at the time. All the expert witnesses agreed that such operations are 85 to 90 per cent successful but that about 1 per cent of such operations result in death, so that 9 to 14 per cent result either in failure or only in partial success. There was also some evidence to the effect that in some cases the operation resulted in increased disability. The petitioners offered the operation by certain specific doctors and in certain specific hospitals, all of which tenders were refused, and then the petitioners extended the tender to include any hospital or surgeon or any neurologic surgeon or hospital of good reputation comparable to those mentioned in the specific tender, which included the Mayo Clinic and Johns Hopkins.

The employer contended that the claimant's disability should be declared to be temporary rather than permanent because of the claimant's refusal to submit to a surgical operation recommended by the physicians. The petitioners cited a number of cases in which it was held that, where the injury complained of is of such a character as to require skilled and professional needs to determine the cause and extent thereof, the question is one of science and must be proved by the testimony of professional persons. Such is the rule, but in this case all the expert witnesses testified that in their opinion the claimant's injury was a ruptured or fractured intervertebral disk, that his disability was permanent unless relieved by a surgical operation and that the operation indicated was a major operation, successful to the extent of 85 to 90 per cent, with about 1 per cent resulting in death.

The rule appears to be, said the Supreme Court, that "where an employee seeking compensation under the Workmen's Compensation Law of Oklahoma, unreasonably refuses to undergo a minor operation, safe, simple and reasonably certain to effect a cure, the continuing disability results not from the injury but from his own willful act." "Equally true is the rule . . . that the Industrial Commission has no authority to compel an employee to submit to a major operation where there is a risk of life involved in the 'slightest degree.'" In a prior case the Supreme Court of Oklahoma held that the Industrial Commission is without jurisdiction to order an injured employee to submit to an operation involving a risk of life, however slight, merely in order that the pecuniary obligations created by law in his favor against his employer may be minimized. Under the decisions of this court, the Supreme Court concluded, it cannot therefore be said as a matter of law and in the face of all the testimony of the expert, skilled witnesses in this case that the operation recommended is not a major operation, that there is no risk of life involved in such an operation or that under the record claimant's refusal to submit to an operation was unreasonable. The award in favor of the claimant was therefore affirmed.—*K. Lee Williams Theatres, Inc., v. Mickle, 205 P. (2d) 513 (Oklahoma, 1949).*

**Malpractice: Surgeon's Liability for Negligence of Intern.**—The plaintiff's father, as guardian of his infant daughter and also in his own right, filed suit to recover damages for injuries to the eyes of his newborn child allegedly caused by the improper application of silver nitrate solution. From a verdict of nonsuit in favor of the defendant physician, the plaintiff appealed to the Supreme Court of Pennsylvania.

The plaintiff and his wife engaged the defendant physician to attend the wife during her pregnancy and to deliver her of an expected child. A cesarian operation was necessary, and when the time arrived the defendant asked that a certain intern, whose name he mentioned, should be informed that "he was to be his assistant and take care of the baby at the time of the delivery." When the child was delivered the defendant turned it over to the intern for the purpose of tying the cord and applying a solution of silver nitrate to the infant's eyes. Silver nitrate is an extremely caustic drug, and proper technic calls for the application of only 1 or 2 drops in each eye followed by prompt irrigation. A subsequent analysis of the silver nitrate used on this occasion revealed that it was a 2.1 [per cent] solution which, it was testified, was not of excessive intensity. The insertion of silver nitrate or other approved prophylactic agent in the eyes of every newborn child is not only a regularly established practice in obstetric cases but is required by the rules and regulations of the Department of Health of the Commonwealth, the purpose being to prevent the disease known as ophthalmia neonatorum. According to the testimony of the special nurse engaged to take care of the wife, the intern filled a syringe and squirted the solution once into the child's left eye and twice into its right eye, putting into the latter "a great many drops"; moreover, he failed to irrigate the eyes during at least the period of five or ten minutes while this nurse remained in the operating room. The result was that the child lost the sight of her right eye completely and the left eye was severely and permanently scarred.

It was the plaintiff's contention that this case should have been submitted to the jury and that the trial court erred in negating the defendant's responsibility as a matter of law. The plaintiff did not charge the defendant personally with any act of negligence either of commission or omission; it was apparently conceded that he was an obstetrician of high repute and that the operation he performed on the wife was entirely satisfactory and not subject to criticism. On the other hand, the plaintiff's testimony made out a prima facie case of negligence against the intern. Therefore, the only legal question involved, said the court, is whether or not the doctrine of respondent superior applies, that is to say, whether or not, for the purpose of and during the course of the operation, which included the immediate care of the infant child, the intern was, in the view of the law, the servant or employee of the defendant physician.

The general principles of law applicable to the situation, said the Supreme Court, are not only clear but so firmly established that there is no need to explore any new and hitherto uncharted pathway in the law. These applicable principles are as follows: 1. In the determination of whether a person is the servant of another, the essential test is whether he is subject to the latter's control or right of control with respect not only to the work to be done but also to the manner of performing it. 2. A servant directed or permitted by his master to perform services for another may become the servant of such other in performing the services; he may become the other's servant as to some acts and not as to others. 3. A person may be the servant of two masters, not joint employers at one time as to one act, provided that the service to one does not involve abandonment of the service to the other. 4. When different inferences can fairly be drawn from the evidence as to who is the controlling master of the borrowed employee at the time of the commission of the negligent act, it is for the jury, not the court, to determine the question of agency.

In applying these principles of agency to the present case, said the Supreme Court, it is to be noted at the outset that the defendant's obligation under his contract included not only the wife's prenatal care and the delivery of her child but also the care of the latter until it was turned over to the family physician. The wife testified that the defendant said that he would "perform a cesarian operation and care for the baby for the sum of $200." The defendant himself, when asked whether or not his liability was to continue until the baby was turned over to the family doctor, answered, "I so considered that it was." It may well have been in contemplation that he might need help in taking care of the newborn infant, and, as it subsequently turned out, such help was essential. The necessity of employing assistants is one of the ordinary circumstances of both business and professional life, and it is to regulate just such situations that the law of agency exists. In selecting a person to aid him, the defendant was presumably free to make his own choice; there is nothing in the record to indicate that he was compelled to employ an intern. What he chose to do was to call for and borrow from the hospital an intern who thereby became—or so, at least, a jury might find—his temporary servant or employee for the purpose he was engaged.

The next important fact to be considered, the Supreme Court continued, is that the defendant himself testified that he had complete control of the operating room and of every person within it while the operation was in progress. Asked whether the intern was bound to carry out his orders, his answer was, "That is correct." It can readily be understood, said the court, that, in the course of an operation in the operating room of a hospital and until he leaves that room at the conclusion of the operation, the surgeon is in complete charge of those who are present and assisting him and that such supreme control is indeed essential in view of the high degree of protection to which an anesthetized, unconscious patient is entitled—a protection which the wife could justly claim in this case by reason of her trust and confidence in, and necessary reliance on, the surgeon she has employed to take care of her and her child when born.

If, then, it be true that defendant had supervisory control and the right to give orders to the intern with respect to the very act in the performance of which the latter was negligent, it would follow, according to the classic test of agency hereinbefore stated, that a jury would be justified in concluding that the temporary relationship between the defendant and the intern was that of master and servant and that consequently the defendant was legally liable for the harm caused by the intern's negligence.

It was urged by the defendant that the rule of law in regard to a "borrowed employee" should not apply where the employee is a regular part of the personnel of a public or quasipublic hospital, but such an employee, said the Supreme Court, can be temporarily detached, in whole or in part, from the hospital's general control. As far as the evidence disclosed, it was the defendant, not the hospital, who assigned the intern to the task of inserting the silver nitrate solution into the infant's eyes, and, even if in the performance of that act he may also have been serving the hospital, that fact would not change his legal status with respect to the defendant, since a borrowed employee may, in the performance of a given act, be serving the interests of both his general employer and his temporary master.

In the present case, said the Supreme Court, the court erred in entering a nonsuit. It was for the jury to determine whether the relationship between the defendant and the intern, at the time the child's eyes were injured, was that of master and servant. In the determination of whether the intern was the defendant's servant at that time, the mere fact that he was then in the general employ of the hospital would not prevent the jury from finding that he was also at that same time the servant of the defendant if he was then subject to his orders with respect to the treatment of the child's eyes with the silver nitrate solution. Accordingly the nonsuit in favor of the defendant physician was reversed and the cause remanded for a new trial.—*McConnell v. Williams (two cases), 65 A. (2d) 243 (Pa., 1949).*

## AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1938 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

**Influenza Vaccine.**—Bruyn and associates inoculated subcutaneously or intradermally a total of 79 children with combined type A and type B influenza virus vaccine. Febrile reactions, with temperatures usually over 101 F., and commonly malaise and headache and occasionally vomiting occurred in more than half the children receiving vaccine subcutaneously. The reactions following intradermal inoculation with either one dose of 0.1 cc. or two doses of 0.1 cc. were approximately half as frequent as those following subcutaneous inoculation and were not accompanied with either high temperatures or constitutional symptoms. The serologic response to vaccination with influenza virus vaccine was comparable in all groups with the results for adults. The two doses of 0.1 cc. given three days apart produced the most satisfactory results. The prevaccination titers to type A influenza in these children were approximately in proportion to age.

**Essential Xanthomatosis.**—Schick and Sperry recorded in 1936 results of a year's study on a boy who when first seen presented a picture of severe xanthoma tuberosum with pronounced hypercholesteremia. The patient lived thirteen years on a diet free of cholesterol. Despite this regimen, he continued to exhibit pronounced hypercholesteremia and no regression of the disease was noted. The only effects which may be attributed to the cholesterol-free diet were a relatively small decrease in the average cholesterol concentration of the blood serum and the fact that no new lesions appeared. Treatment with thyroid, insulin, lipocaic, vitamin B complex and ultraviolet radiation had no noticeable effect. The patient's mother and father were both hypercholesteremic, and 1 brother maintained an abnormally high concentration of cholesterol in his blood serum. In a second brother the serum cholesterol level frequently exceeded 300 mg. per hundred cubic centimeters but was within the range for supposedly healthy persons. The observations on this family emphasize the heredofamilial nature of essential xanthomatosis and support the concept that inherited hypercholesteremia is the primary disturbance in this disease.

**Roentgen Manifestations of Erythroblastosis Fetalis.**—Ritvo and co-workers say that studies carried out at the Boston City Hospital indicate that roentgen studies of the fetus in utero afford valuable data and may permit of a diagnosis of erythroblastosis fetalis in certain instances. The roentgen observations in erythroblastosis fetalis comprise (1) soft tissue changes consisting of generalized edema and enlargement of the liver and spleen, (2) abnormalities of the skeleton, with increased densities in the bones, and (3) evidences of fetal death.

**Hodgkin's Disease.**—Sahyoun and Eisenberg report 24 cases in which they attempted to correlate the histopathologic aspects with the clinical course and the prognosis. They offer a classification of Hodgkin's disease based on histologic criteria and approximate range of life expectancy. First there is the compactly cellular type, in which the progress is slow and life expectancy is between forty-eight and one hundred and sixty months. The second is the fibrogranulomatous type, which is moderately progressive; the patients with this form can be expected to survive for twenty to sixty months. The third, the loosely cellular type, is rapidly progressive; patients with this form survive only twelve to twenty months. The authors discuss the response to roentgen irradiation and the correlation between the expected course based on histologic study, and the actual course. Nineteen of the 24 cases were followed adequately and in 17 of these 19 the course coincided with the prognosis from histologic study.

Infectious Diseases: Fourteenth Annual Review of Significant Publications. H. A. Reimann.—p. 468.

**Paroxysmal Tachycardia.**—Wolff and White report a new series of 41 patients, 28 men and 13 women, 21 between the ages of 13 and 29 and 18 between the ages of 30 and 76, with a syndrome of short P-R interval, wide QRS waves and paroxysmal tachycardia. In a previously reported series of 11 patients with this syndrome 10 were less than 29 years old. Paroxysmal tachycardia occurred in 25 cases of the new series and in 10 of the original 11 cases, making a total of 35 cases with paroxysmal tachycardia in the combined series of 52 cases. Analysis of the 52 cases indicates that this syndrome occurs most commonly in young persons, more often in men than in women and in healthy persons from early childhood to old age. Paroxysmal tachycardia is compatible with good health and strenuous activity and does not predispose to the development of heart disease, although congestive failure rarely may result from prolonged, uncontrolled tachycardia. Except for symptoms due to paroxysmal tachycardia and rare instances of sudden death, none of which occurred in the authors' cases, the abnormal mechanism is asymptomatic and does not affect the prognosis in cases of intercurrent disease, surgical procedures or pregnancy and does not affect longevity. The abnormal electrocardiogram was frequently misinterpreted leading to an erroneous diagnosis of serious heart disease or of paroxysmal ventricular tachycardia in more than one third of the cases. If many electrocardiograms are taken, there is a greater probability of recording normal as well as abnormal ventricular complexes, and if the P-R intervals of the normal and the abnormal ventricular complexes are identical it may be assumed that the abnormal electrocardiogram is due to an accessory conducting pathway with a short conduction interval. Such a pathway would make possible the premature depolarization of part of the ventricular muscle and offers a possible explanation for paroxysmal tachycardia. One of the factors which determines whether or not the QRS complex represents an interference phenomenon or depolarization wholly through the anomalous route is the degree of shortening of the anomalous P-R interval. The critical value depends on many factors but is probably close to 0.08 second. Digitalis may or may not widen the anomalous ventricular complex. In 1 case of auricular fibrillation with anomalous QRS waves, digitalis was ineffective in controlling the ventricular rate.

**Residual Pulmonary Lesion in Coccidioidomycosis.**—Bass and associates feel that coccidioidomycosis should no longer be considered a rare disease confined to a small endemic area (the San Joaquin Valley in California). The endemic areas in the United States include Western Texas, Southern New Mexico, Southern and Central Arizona, Southwest Utah and possibly Southern Nevada, and a number of areas in Southern California, in addition to the San Joaquin Valley. The incidence of infection in military personnel who spent part of their military service in the endemic areas was 25 per cent. One's merely driving through an endemic area can result in infection. Any person who presents a pulmonary infiltration in which the diagnosis cannot be readily established should be questioned as to exposure in an endemic area. The authors present observations of 20 veterans of World War II, who had residual lesions of pulmonary coccidioidomycosis. The residual lesions persisted two to five years after the initial infection. The residual lesions were of various types: nodular densities, cavities, mottled infiltrations, fibrosis, pleural effusion and calcification. Skin sensitivity to coccidioidin was observed to diminish with the lapse of time. In cases of cavity formation, no evidence of bronchogenic spread or of seeding to other parts of the lung fields, such as occurs commonly in tuberculosis, was observed. In several of the cases a diagnosis of tuberculosis had been made after the patient's return to civilian life, usually after a routine examination of the chest or preemployment roentgenographic examination. In a number of cases a positive reaction to both the tuberculin and the coccidioidin skin test made diagnosis difficult, but a history of exposure in an endemic area, absence of tubercule bacilli and certain roentgenologic aspects justified a presumptive diagnosis of coccidioidomycosis. Almost all the patients were asymptomatic.

**Use of Polymyxin, Chloromycetin and Aureomycin.**—During the past eighteen months three new antibiotic agents, polymyxin, chloromycetin and aureomycin have been described. Long and co-workers state that polymyxin is an effective antibiotic for the treatment of severe infections produced by Pseudomonas aeruginosa, Hemophilus pertussis, Hemophilus influenzae, Escherichia coli and Aerobacter aerogenes. Its toxicity to date precludes its general use in infections susceptible to its therapeutic effects. Chloromycetin has been demonstrated to be an effective antibiotic agent for the treatment of rickettsial diseases and typhoid fever. It will undoubtedly prove effective in the treatment of other infections produced by certain gram-negative micro-organisms and viral agents. Aureomycin has been shown to be an active antibiotic agent against rickettsial diseases, primary atypical pneumonia, acute brucellosis, pneumococcic, streptococcic and staphylococcic infections, urinary tract infections produced by E. coli, A. aerogenes and Streptococcus fecalis, certain types of infections of the eye and in subacute bacterial endocarditis when the infecting agent is Str. fecalis. Its clinical use in forms of extrapulmonary tuberculosis is in a completely experimental stage. It is not recommended in typhoid fever or in infections due to Ps. aeruginosa or Proteus vulgaris, and it seems to be ineffective in whooping cough. To date, neither chloromycetin nor aureomycin has resulted in significant signs of systemic toxicity.

**Kidney Substitutes in Uremia.**—Palmer and Rutherford refer to reports by Kolff, whose dialyzer they used for explanation of the principles involved and of the technic. The dialyzer consists basically of a long cellophane tube wound spirally around a wooden drum which rotates through a large water bath containing essential electrolytes and dextrose. A special hollow axle and rotation coupling at each end permit continuous blood flow during the drum rotation. All parts in contact with the blood are kept sterile. The authors describe their experience with Kolff's dialyzer in 2 patients. In 1 of these the treatment appeared to play a major role in recovery. Kolff's dialyzer is effective in the reduction of uremia and may aid in the immediate recovery of renal function. The authors discuss the indications for the use of kidney substitutes and recommend the early employment of effective kidney substitutes.

**Clinical Trials of Antabuse.**—According to Bell and Smith antabuse is the Danish trade name for tetraethylthiuramdisulfide. Patients receiving this drug have an abnormal reaction to alcohol in the body. This drug itself has few effects when administered in daily doses of 0.5 Gm. over a period of several months. The symptoms produced by alcohol after administration of antabuse are probably due to interference with the oxidation of alcohol, so that abnormally high levels of acetaldehyde are produced in the body. The report is mainly concerned with the symptoms produced when alcohol is taken after antabuse. Their experiences confirm the results obtained by Jacobsen and associates in Denmark. In accordance with Jacobsen's recommendation that any physician considering the administration of antabuse to his alcoholic patients should first try the effects of antabuse plus alcohol on himself, the first trial was conducted with the authors as subjects. After antabuse was taken (0.5 Gm. daily for four days), alcohol was administered and the effects were observed. The authors experienced the symptoms outlined by Hald and associates, with some additions. The authors describe their observations of alcoholic patients. They gained the impression that the factors concerned in the rate of accumulation of alcohol in the blood are partly responsible for the severity of symptoms seen when a certain quantity of alcohol is administered to a patient who has previously received antabuse. No means of controlling the severity of the reaction has yet been devised. No antabuse should be given until it is certain that the patient is free of alcohol. Serious consequences are to be expected if antabuse is taken while there are appreciable amounts of alcohol in the body. It should not be given to "sober up" an alcoholic person.

**BAL in Mercury Poisoning.**—Kanee and Stoffman report the case of a 2 year old girl for whom gray powder (mercury with chalk) containing 33 per cent mercury was prescribed in a daily dose of ½ grain (30 mg.) for constipation. At the same time yellow mercuric oxide ointment, 2 per cent, was prescribed once daily for a small meibomian cyst of the right lower eyelid. The child showed signs of mercury poisoning, which failed to respond to treatment until BAL (2,3-dimercaptopropanol) was given. Dosage based on 3 mg. per kilogram of body weight was 0.35 cc. of 10 per cent BAL in oil, every four hours for forty-eight hours. On the third day injections were reduced to four, and thereafter one injection was given daily for four more days. The child was discharged eight days after commencement of BAL therapy, the rash having almost completely faded and the temperature having been normal for three days previously.

**Poisoning Due to Ingestion of Wax Crayons.**—Minor reports a child, aged 2, in whom symptoms of acute poisoning developed following ingestion of orange and yellow crayons. No other source of poisoning could be discovered, and, therefore, this case was assumed to be one of paranitraniline poisoning. The literature contains reports of many such cases, in infants and as an industrial hazard. According to Jones and Brieger, parared, an organic pigment, is made by combination of diazotized paranitraniline with beta naphthol; they point out that orange and red-orange crayons contain parared whereas red and yellow-red crayons are free from it. The child recovered. It seems important that the child ingested wax crayons on an empty stomach, since it has been proved that animals with full stomachs can tolerate larger doses of paranitraniline than those with empty stomachs.

**Pain and Hyperamylasemia in Carcinoma.**—Ross and Klinge report 30 patients, 23 men and 7 women between the ages of 31 and 83, with carcinoma of the head of the pancreas and 10 patients, 8 men and 2 women between the ages of 24 and 68, with carcinoma of the ampula of Vater. Twenty-five of the first group had pain, most often located in the epigastrium or right upper quadrant. Only 2 of the second group had any pain, and in both of these there was coincident gallbladder disease. Even in these 2 cases of pain in ampullary carcinoma, pain did not precede the jaundice; whereas, with carcinoma of the head of the pancreas, pain consistently preceded jaundice. The average duration of symptoms was 4.6 months in carcinoma of the pancreas and 2.8 months in ampullary carcinoma. The average duration of jaundice was essentially the same for the two groups. The serum amylase was elevated in one third of the cases of carcinoma of the head of the pancreas and in all but 1 case of ampullary carcinoma. A correlation of the serum amylase level with the duration of symptoms is demonstrated, the amylase levels being elevated early in the course of the disease. The determination of serum amylase in patients with unexplained abdominal pain may lead to earlier diagnosis of carcinoma of the pancreas and of the ampulla of Vater.

**Tetraethylammonium Chloride in Peptic Ulcer.**—Cayer and co-workers treated 12 patients with active duodenal ulcer who were having pain while being treated with diet, bed rest, sedation and antispasmodics, with tetraethylammonium chloride given intramuscularly three times daily between meals and at bedtime. The intital dose of 300 mg. was increased by 100 mg. per dose until the patient was receiving 600 mg. at each injection. Pain was relieved in fifteen to twenty minutes, and when tetraethylammonium chloride therapy was continued between feedings pain could usually be prevented. Ulcer symptoms can usually be controlled during the day by dietary and other less experimental means. The most satisfactory results in the authors' cases were obtained in patients with persistent night pain; the alleviation of pain allowed the patient at least six hours of undisturbed rest. Unpleasant side effects from the drug were minimal. No alteration of gastrointestinal motility was noted in roentgenologic examination, but there appeared to be some diminution in the secretion of free acid. The relief of pain provided by the drug may be due to an alteration in the response of the circulation of the gastric mucosa.

**Benign Paroxysmal Peritonitis.**—Siegal reports, in addition to the 5 cases of benign paroxysmal peritonitis described by him in 1945, 6 new cases in 3 men between the ages of 29 and 32 and in 3 women between the ages of 28 and 63. This disease begins early in life and continues for many years. It is characterized by recurrent paroxysms of abdominal pain with signs of peritoneal irritation. Fever is present, ranging from 100 F. (37.8 C.) to 105 F. (41.5 C.). Leukocytosis and polymorphonucleosis are frequent in the attack. Chest pain, worse on inspiration, is a common accompaniment. Intervals between episodes, most often one to four weeks, may involve months or even years. These patients remain otherwise well. The practical difficulties of diagnosis must be emphasized particularly as to differentiation from an acute surgical abdominal condition, such as that due to appendicitis. Three patients were operated on during an acute attack. Hyperemia or edema of the peritoneum, with or without serous or serofibrinous exudate, comprise the operative observations. Results of exploration after an interval of several years have been normal. The occurrence of this disease in 5 male members of a single family indicates a definite familial tendency and possibly a genetic factor. All published cases which appear to belong to this clinical category have been either in Jewish or Armenian patients. Benign paroxysmal peritonitis possesses many of the clinical attributes of an allergic disorder. Of 11 patients, 2 had atopic conditions and 4 more had a definite family history of allergy, but causative food allergens were not demonstrated in any of 5 cases completely studied from this point of view. Neither epinephrine nor the antihistamine drugs control the acute attack.

**Masculinizing Ovarian Tumor of Adrenal Type.**—Mortell reports a woman, aged 46, who had begun to show signs of masculinization at the age of 40. Generalized hirsutism, baldness, masculine contours and enlargement of the clitoris gradually developed. Preoperative urinary excretion of 17-ketosteroids was 8 mg. in twenty-four hours. Bilateral oophorectomy and supravaginal hysterectomy were performed. Both ovaries were somewhat larger than normal, and the right ovary was larger than the left. Section of the right ovary showed the smooth circular outline of a solid tumor, about 18 mm. in diameter. The tumor had no capsule, but there was no sign of infiltrating growth. Examination of sections of the tumor led to the diagnosis of adrenal tumor of the ovary. After removal of the tumor there was considerable regression of the masculinization.

**Para-Aminobenzoic Acid in Rocky Mountain Spotted Fever.**—Hooten, Hooten and Mitchell point out that Rocky Mountain spotted fever was first thought to occur only in the area for which it is named, but it has since been reported from every section of the United States. They review previous reports on the use of para-aminobenzoic acid in the treatment of this condition and the experiences with this drug in 12 cases treated by themselves and in 48 cases from the literature. Seven of the 12 patients treated by them are reported in detail. The amount of para-aminobenzoic acid required varies, but the blood level should be maintained between 20 and 60 mg. per hundred cubic centimeters. In adults this level can usually be maintained by an initial dose of 8 Gm. and then 2 Gm. every two hours. The 48 cases from the literature and the 12 cases just reported show an almost uniformly good response to treatment with para-aminobenzoic acid. There were 4 deaths (mortality rate of 6.7 per cent). Clinical improvement was usually noted in twenty-four to forty-eight hours after the beginning of para-aminobenzoic acid therapy, and the duration of fever was about one week shorter than in patients who did not receive the drug. The authors feel that para-aminobenzoic acid is now the drug of choice in the treatment of Rocky Mountain spotted fever.

**Pulmonary Collapse in Pertussis.**—Nicholson reviews the literature relating to pertussis and bronchiectasis and presents observations on a series of 44 children with pertussis, most of them with a type severe enough to warrant admission to a hospital. These children were examined frequently. The shadows seen on the radiographs were usually typical of lobar or segmental collapse, mainly of the middle and lower lobes. Evidence in favor of the shadows representing collapsed lobe was as follows: (1) physical signs of collapse and lack of response to chemotherapy; (2) association of mediastinal shift and compensatory emphysema; (3) the presence in some radiographs of visibly dilated bronchi in the shadow; (4) the similarity of the shadows with the triangular basal shadows. Collapse of over two months' duration was seen in 1 out of 4 mild cases, 9 out of 16 moderate cases, and 13 out of 17 severe cases, that were followed for a sufficient length of time. If collapse is still present after the acute stage is over further treatment is imperative, and should be directed at the collapsed lobe. Postural drainage in the appropriate position should be given and this should be combined with percussion over the affected lobe in an attempt to induce the child to cough up the particles of sputum. Treatment in this manner can be given several times a day and must be given until all hope of re-expansion is abandoned. If reexpansion does not occur within nine months it is unlikely to do so, and bronchiectasis may supervene and surgery may become necessary. Many cases of postpertussis pulmonary collapse still go unrecognized, and all too often the treatment consists of an ineffective cough mixture.

Dublin Surgery 100 Years Ago. W. Doolin.—p. 97.
*Pneumoperitoneum and Phrenic Paralysis in Treatment of Pulmonary Tuberculosis: Report on 188 Cases. M. Hanrahan.—p. 112.
Note on Use of Radium in Conjunction with Surgery in Gynecology. R. E. Tottenham.—p. 125.

**Pneumoperitoneum and Phrenic Paralysis.**—Hanrahan treated 57 patients with pulmonary tuberculosis with pneumoperitoneum only. Quiescence was achieved in 1 case and improvement in 21 cases; in 11 cases the condition was unchanged and in 24 it became worse. Pneumoperitoneum alone seems to be of little or no benefit, and it should be abandoned or used sparingly. Phrenic paralysis reinforced by pneumoperitoneum was carried out in 131 patients with pulmonary tuberculosis. Quiescence was achieved in 25 cases and improvement in 57; 19 patients were unchanged and 30 became worse. These results show that the majority of cases will require some other form of treatment if quiescence is to be achieved. In 6 of 43 patients in whom pneumoperitoneum and phrenic paralysis had been instituted after attempts to induce pneumothorax had failed the disease became quiescent; 24 in this group were improved; 7 were unchanged and 6 deteriorated, suggesting that pneumoperitoneum and phrenic paralysis are of little value in cases in which visceral and parietal pleurae are widely adherent. Quiescence was established in 12 patients, and 15 were improved in a group of 38 patients in whom pneumoperitoneum and phrenic paralysis were instituted after abandonment of pneumothorax because of fluid or contralateral spread, thus giving a good prospect of satisfactory results following the abandonment of pneumothorax. Quiescence was established in 5 patients, and 4 were improved in a group of 10 patients in whom phrenic paralysis and pneumoperitoneum were instituted complementary to pneumothorax, suggesting that this combined treatment deserves further trial. Results were best with pneumoperitoneum and phrenic paralysis in lower zone disease with cavitation below the hilus, when a partial pneumothorax was conducted simultaneously and where the pleura was relatively free, i. e., after pneumothorax had been abandoned. Pneumoperitoneum and phrenic paralysis had a favorable effect in only a small proportion of cases of cavitation situated above the hilus. Each case must be judged on its merits, and if the treatment is having the desired effect phrenic paralysis and pneumoperitoneum should be maintained for at least three years.

*Transorbital Leukotomy. G. W. T. H. Fleming and D. G. Phillips.—p. 197.
*Chess as Form of Recreational Therapy. R. Pakenham-Walsh.—p. 203.

**Transorbital Leukotomy.**—Fleming and Phillips review observations of 8 patients who had been subjected to transorbital leukotomy. The technic employed was that described by Freeman. Although all of these patients had a poor prognosis, 7 of the 8 patients showed improvement after transorbital leukotomy. Of 5 patients with depression, 1 recovered completely and the other 4 were improved. One patient with paranoid schizophrenia recovered; another schizophrenic patient was much improved, but a third one appeared to be worse. Two of these patients could not have been operated on by ordinary leukotomy without great risk.

**Chess in Recreational Therapy.**—Pakenham-Walsh discusses his experience with chess games in a mental hospital. Although the object of this report is mainly to stimulate similar activity in other mental hospitals and to bring chess into line with cricket and football, so that interhospital matches could be arranged, he suggests that chess is not merely another form of recreation therapy but that it is an intelligence test of which much use could be made. If a player were to play a series of recorded games both before and after leukotomy, it might be possible to detect changes not only in the intelligence but in the personality, e. g., the cautious player might become reckless, or the man who plays a good attacking game might change to a defensive player.

*Use of Thrombin in Liver Puncture. L. Friedrich and M. Policzer.—p. 523.

**Necrotic Jejunitis.**—Fick and Wolken direct attention to an apparently endemic, severe and often fatal lesion of the jejunum, observed during the past few years in Northern Germany. Though sometimes there is a short prodromal stage, the onset is usually acute with violent pain in the upper part of the abdomen. Often the pain is located a little to the left of the midline and is associated with a hyperesthetic Head zone from the seventh to the twelfth thoracic segment on the left side and a reflex rigidity of the abdominal wall in the same segments. At the same time the patient usually suffers from nausea and vomiting. The most striking clinical feature is circulatory collapse due to toxemia. The patient may die within twenty-four hours after the onset of the first symptoms. Those who survive this stage pass into either a condition characterized by enteritis with bloodstained diarrhea or a condition of intestinal obstruction resembling paralytic ileus. The histologic picture in the gut is that of fairly generalized necrosis. The disease is thought to be a specific infection to which one is predisposed by defects of diet. Since this paper was written, a new bacillus has been discovered in the intestinal lumen in some cases of jejunitis by Zeissler of Hamburg. This bacterium, previously unrecognized, is an anaerobe of the Clostridium welchii group. It forms a powerful toxin. It is closely related to another bacillus of the same group of Cl. welchii, which causes dysentery in lambs, a condition characterized by severe enteritis. Zeissler holds that his organism, which he names Clostridium enterotoxicus or Cl. welchii type F, plays an important part in the causation of jejunitis. It has also been found in healthy persons in Northern Germany. Should further research confirm Zeissler's opinion about this organism, it would also confirm the opinion held by the authors that necrotic jejunitis is a specific infection the manifestation of which depends on certain other factors.

**Thrombin in Liver Puncture.**—According to Friedrich and Policzer of Budapest, the greatest risk in liver puncture is hemorrhage. After satisfying themselves that it did no harm to the liver tissue in the cadaver, the authors adopted a method in which commercial thrombin is injected into the needle track after the biopsy specimen is withdrawn. The thrombin is provided in powder form. The solvent, put up in separate phials, contains pyrocatechin and calcium chloride, to enhance thrombin activity, and sodium chloride and tricresol, to insure sterility and stability. The authors have obtained the best effects with a solution containing 200 coagulation units in 1 cc. of solvent. The liver puncture needle used is double, the outer needle being 12 cm. long and 2 mm. in bore and the inner 1.4 mm. in bore and fitted with a stylet. The outer needle is graduated in centimeters, and a depth screw is provided to control the depth of the puncture. Apart from the effect of thrombin solution, the authors ascribe the freedom from complications in their cases to the use of a needle which will not pass more than 3 cm. into the liver.

Radiologic Interpretation and Pulmonary Tuberculosis in Adult. M. R. de Lambert.—p. 203.
Pulmonary Tuberculosis in the Elderly. K. H. Hallam.—p. 206.

**Resection of Lung for Pulmonary Tuberculosis.**—Brown lists the following conditions as indications for pulmonary resection in tuberculous patients: (1) high grade bronchial stenosis, with or without associated suppurative disease; (2) tuberculoma; (3) cavity persisting after thoracoplasty; (4) lower lobe cavities which have resisted other methods of treatment, and (5) massive acute tuberculosis which is unilobar or unilateral, when the patient's condition is deteriorating, despite bed rest and streptomycin. He reviews his experiences in 11 pneumonectomies and 7 lobectomies and stresses that resection has established itself as a valuable treatment in certain forms of pulmonary tuberculosis. It is not an alternative to thoracoplasty, but should be used for cases in which thoracoplasty is inapplicable or has failed. Most of the patients selected for resection have no other chance of getting well, and the undoubted risks are justified by the successes. Streptomycin is probably of real value to cover the immediate postoperative period and to control postoperative spread.

*Structure of Liver in Fatal Burns. J. Gillman and T. Gillman.—p. 169.

**The Liver in Fatal Burns.**—The 38 patients examined by the Gillmans had not received tannic acid in the treatment of their burns. They had died from burns within one hour and as long as thirty-six days after the accident. The authors observed three main types of reactions, namely, loss of stainability of the liver cells, fatty changes and atrophy of cells in the central zone of the lobule. Loss of stainability was seen mainly in the livers of patients dying within forty-eight hours after the accident. Fat, in the form of small and medium-sized droplets, could appear as early as eighteen hours, but it was more consistently observed between thirty-six and seventy-two hours after the accident. Atrophy of the liver cells around the central vein becomes manifest first in a liver thirty-six hours after burns are sustained. The extensive necrosis described in different parts of the world was not observed in this series of cases, probably because tannic acid had not been used on the burns of these patients. Tannic acid presumably intensifies the tendency to necrosis. The authors conclude that in the majority of fatal cases of burns the morphologic changes in the liver were insufficient to account for death. If the liver does contribute to death it does so chemically.

Haverhill Fever (in Connection with Case Observed in Sweden). A. Engel.—p. 562.
Artificial Kidney: VI. Views on Indications for Treatment of Uremia and for Active Removal of Edema by Means of Artificial Kidney, Based on Studies of Uremic Material not Treated with this Method. N. Alwall and B. Herner.—p. 572.
*Id.: Clinical Experiences of Dialytic Treatment of Uremia. N. Alwall, L. Norviit and A. M. Steins.—p. 587.

**Spontaneous Pneumohemothorax.**—Hansen presents 3 cases of spontaneous pneumohemothorax treated at a clinic of thoracic surgery during the spring of 1946. None of them were typical. The symptoms in the first case differed from the usual only in the onset. The patient was hospitalized with a diagnosis of perforated gastric ulcer and was then treated for heart disease. This is by no means a rare variant of the syndrome, and its recognition is important. The other 2 patients exhibited bilateral cystic lung. This cause does not appear to have been observed in the cases published hitherto, or at any rate, not in this form. One of the 2 patients was a woman and one of the few patients over the age of 40 with this type of disorder. In this patient the diagnosis was proved by an operation performed as the last resort after the disease had lasted nineteen days and the symptoms had grown worse. The cysts were so close together that suture of the numerous ruptures was impossible. Thirty-six hours later the patient died in anoxia. Necropsy showed the cysts in both lungs to be so extensive that the normal lung tissue capable of respiration was reduced to practically nothing. A number of the cysts had ruptured. The origin of the hemorrhage could not be demonstrated. In the third patient, a youth of 21, suddenly, without exertion, there developed a pneumohemothorax with severe intrapleural tension which quickly subsided after thoracocentesis. Roentgenographic as well as thoracoscopic examination revealed a cystic lung. In spite of bed rest, closed pulmonary fistula and a constant negative pressure, the right lung showed no tendency to expand. After five weeks a solution of silver nitrate was injected into the pleural cavity. The result was an adhesive pleurisy with rapid expansion of the lung.

**Artificial Kidney: Clinical Experiences.**—Alwall and associates report experiences with dialysis in the first 12 patients treated with a dialyzer of a type in which the cellophane tubing is wrapped round a cylinder of wire netting and is surrounded by a mantle of the same material. In 2 of the 12 reported cases the treatment was repeated after intervals of forty-five and eight days, respectively. Thus, fourteen treatments were given in these 12 cases. Uremia was the reason for dialytic treatment in 9 of the cases, and in 2 severe edema as well as uremia was present. In most of the cases the treatment was carried out under conditions precluding a lasting therapeutic result. The material can thus only show that the method can have therapeutic value, but not to what extent good therapeutic results are to be expected. It offers many valuable experiences for future work.

Bechterew's Disease and Scleroderma; Sclerodystrophic Systemic Diseases. E. Vaubel.—p. 321.
*Usefulness of Maclagan's Thymol Turbidity Test for Differential Diagnosis of Icterus. K. Denninger and A. Goedtler.—p. 326.
*Early Diagnosis of Carcinoma of the Cardia. N. Henning.—p. 329.
Respiratory Insufficiency in Cases of Impediment of Respiratory Movements. H. C. Landen and Ewalda Sürder.—p. 331.

**Thymol Turbidity Test in Icterus.**—Denninger and Goedtler performed Maclagan's thymol turbidity test of hepatic function on 104 patients, 72 of them with icterus and 32 control patients in whom history and clinical examination did not suggest any disease of the liver or of the biliary ducts. The result of the thymol turbidity test was negative in all 32 control patients and in 33 patients with mechanical icterus resulting from obstruction by tumor or stones. The result of the thymol turbidity test was positive in all 36 patients with icterus resulting from parenchymatous disease of the liver. The reaction was negative in only 3 patients with icterus and a partly positive Takata reaction in whom the clinical picture suggested a parenchymatous disease of the liver; the icterus, which might have been mechanical, subsided within a few weeks. In patients with chronic, latent, diffuse hepatic disease, the result of the thymol turbidity test was always positive. It is a reliable index of liver dysfunction in cases of this type. The thymol turbidity test is of great value in the differential diagnosis of jaundice. A great advantage is the technical simplicity of the test.

**Carcinoma of the Cardia.**—Henning reports 52 cases of carcinoma of the cardia in 40 men and 12 women between the ages of 34 and 77. Symptoms were present two months to one year. The first subjective sign was painless dysphagia. Results of roentgenologic examination suggested carcinoma of the fornix involving the cardia in 24 cases; carcinoma was suspected in 20 cases, and cardiospasm was diagnosed in the remaining 8 cases. Endoscopic examination was performed in all 52 cases. The predominant observations in 20 of these cases were a rigid cardia and a more or less narrowed lumen with angular borders. Neoplastic changes above the cardia were not visible. In other cases signs of growth penetrating the wall of the esophagus above the cardia were manifested by a blackish lumen surrounded by four oval, sharply delineated, whitish, flat areas shaped like the jasmin flower. This characteristic picture is a definite aid in differential diagnosis from cardiospasm. Early diagnosis is possible in a much larger percentage of cases of carcinoma of the cardia than carcinoma of other parts of the digestive canal, provided that roentgenologic examination and esophagoscopic examination are performed early for patients with initial dysphagia.

*Forty-Five Blalock Operations for Congenital Cyanosis. P. Santy, M. Bérard, J. Bret and P. Marion.—p. 129.
*Thoughts on Raynaud's Disease with Regard to 35 Observations. P. Wertheimer and R. Guillet.—p. 145.
Modern Treatment for Considerable Destruction of Coverings of Extremities by Trauma. F. Lagrot.—p. 158.
Condition of Cystic Degeneration of Preserved Ovaries. C. Roman.—p. 162.

**Blalock Operation for Congenital Cyanosis.**—Santy and co-workers performed the Blalock operation on 23 boys and 22 girls, between the ages of 23 months and 15 years, from a group of 100 children with congenital cyanosis. The operation was performed only in those children in whom deficient pulmonary circulation had been diagnosed on clinical and roentgenologic examination. In 1 case in which the Blalock operation was attempted, it could not be performed because no pulmonary artery was present on the surgically treated side. In all patients operated on the subclavian artery was used for the anastomosis with the pulmonary artery. As a general rule the anastomoses were carried out by the end to side technic. The anastomosis of the subclavian artery with the pulmonary artery by the end to end method of suture warrants satisfactory functional results and is to be considered safe in difficult cases in which the end to side method appears to be technically impossible. There were 5 operative deaths, 3 from cardiac syncope and 2 from diffuse venous hemorrhage. Five additional patients died in one to thirteen days after the operation, 2 of them from pulmonary edema, 1 from septicemia and 1 from empyema. In 3 operation failed, in 1 because of the absence of the right pulmonary artery and in 2 because of the poor permeability of the anastomosis. The operation was successful in 32 patients with complete transformation of the clinical and roentgenologic symptoms.

**Raynaud's Disease.**—Wertheimer and Guillet report on 35 patients, 20 women between the ages of 23 and 68 and 15 men between the ages of 24 and 70, with Raynaud's disease. The patients had vasomotor disturbances of the extremities manifested by paroxysmal attacks of vasoconstriction from cold, and 26 had ulcerations of the subungual pulp. The average duration of symptoms was ten years. Nineteen patients had mild disturbances in the lower extremities and 6 had severe destructive lesions of the distal part of the upper extremities. Satisfactory results were obtained with periarterial sympathectomy in 2, partial results in 5 and failures in 5. Stellectomy was performed by cervical approach in 35 instances without any serious incident. There was clinical improvement, particularly of the trophic lesions. A cure was obtained only in exceptional instances; sensibility to cold and vasomotor attacks usually persisted, although they were improved. Operation on the thoracic chain of the sympathetic trunk was done in 4 cases, but the follow-up period had not been long enough for definite conclusions. Combined with stellectomy, it may yield more constant results. Surgical treatment should be carried out in this direction, since the value of intervention on the thyroid, parathyroids and adrenals has not been established. The pathogenesis of Raynaud's disease is still unknown.

New Method of Treating Infected Atheroma. O. Arner.—p. 374.
Encephalography in Frontal Lobotomy. B. Köhler.—p. 377.

**Increased Poliomyelitis Morbidity in Older Age Groups and Its Causes.**—Wernstedt says that, with increased urbanization in country districts in Sweden in recent years, improvements in road systems and means of travel and more intensive movement to the cities, persons of low immunity from rural districts have been brought into livelier contact with urban populations and have been exposed to greater risk of poliomyelitis infection. This applies particularly to older children and adults, who are mainly the ones to travel and to settle in cities and densely populated areas for purposes of education or employment in industry or trade. The result has been an increase in the incidence of poliomyelitis in these age groups.

**Tests of Air Disinfection by Triethylene Glycol.**—Gedda reports on two series of tests of the efficacy of air disinfection with vaporized triethylene glycol in public places—a clinic waiting room and a children's home nursery. Similar tests of bacterial concentration without the use of glycol were carried out for the same number of days. Bacterial count with the Bourdillon apparatus showed an average reduction of about 30 per cent in the first series and about 40 per cent in the second. The relative humidity was 35 to 60 per cent in the waiting room and 70 to 80 per cent in the nursery.

*Penicillin in Therapy of Gonococcic Vulvovaginitis in Little Girls. A. Visani.—p. 1.
*Penicillin Areosols in Treatment of Nontuberculous Diseases of Lung. M. Scarzella.—p. 12.

**Penicillin Therapy of Gonococcic Vulvovaginitis.**—Visani treated gonococcic vulvovaginitis in 13 girls between the ages of 4 and 10 years. The disease was chronic in 9 and acute in 4. Previous sulfonamide therapy and local antiseptic treatment with or without vaccines had failed. Penicillin was given intramuscularly in doses of 20,000 units every three hours up to a total of 300,000 units. Local penicillin treatment was continued for ten days after discontinuation of the systemic treatment. The treatment was well tolerated. The secretion rapidly became negative for gonococci. Cure for more than one year was obtained in the 4 cases of acute disease and in 7 of chronic disease. Two of the patients with chronic disease had either a recurrence or a reinfection one year after discontinuation of the penicillin therapy, which was repeated successfully. The treatment failed in 2 cases of chronic disease. Penicillin therapy is of great value in gonococcic vulvovaginitis in young girls. In patients who do not react favorably to the treatment, the administration of autovaccines and of estrogens, before or combined with systemic and local penicillin treatment, is indicated.

**Penicillin Areosols in Diseases of Lung.**—Scarzella practiced penicillin areosol treatment in 52 patients with various types of nontuberculous infection of the lung. The group included 47 infants and children and 5 young adults. The daily dose of penicillin used in the preparation of areosols varied from 25,000 to 50,000 units. The treatment was given every eight hours for ten to fifteen minutes for a series of ten or twelve treatments. Best results were obtained in acute abscess of the lung, in acute and chronic bronchitis and in bronchiectasis without pulmonary fibrosis. The improvement from the treatment was moderate in chronic abscess of the lung and in bronchiectasis with fibrosis. In all cases fever disappeared, the patient's general condition improved, the amount of sputum diminished and the sputum became odorless. Penicillin areosols proved to be of great therapeutic value in chronic rhinopharyngitis, especially when it was complicated with otitis. The treatment is also of value in adenoiditis and in inflammation of the lymphatic ring after tonsillectomy.

Where are We Standing in Fighting Tuberculosis? A. Grumbach. —p. 249.
*Vaccination Against Tuberculosis. A. Delachaux.—p. 253.
*Importance of Tuberculous Bovine Infection for Man. H. Wissler and P. Meister.—p. 259.
Increased Incidence of Anicteric Hepatitis. W. Fritschy and U. Staubli.—p. 261.

**Vaccination Against Tuberculosis.**—Delachaux reports statistical data concerning student nurses in three hospitals in the French section of Switzerland. During the period of 1935 to 1942, before BCG vaccination was instituted, the rate of infection was 14 per cent among the nurses with a negative skin reaction. BCG vaccination during the period of 1943 to 1947 reduced the rate of infection to 3 per cent; the morbidity rate of vaccinated negative reactors as compared with nonvaccinated negative reactors is 1:4.7. BCG vaccination may be carried out exclusively on anergic persons, i. e., on those with a negative skin reaction to tuberculin in Mantoux's test with 1 mg. old Koch's tuberculin or 100 units of its protein purified derivative which elicits an infiltrate of a diameter less than 8 mm. There is little untoward reaction, provided that BCG is applied correctly by the parenteral route. Applied incorrectly, BCG causes disturbances only in an area strongly allergic to tuberculin. BCG is less apt to elicit local, focal or general reactions than the tuberculin. BCG acts by replacing the natural primary inoculation, which always involves a great risk because of its possible virulence. BCG induces an effective protection against the primosecondary complications. Immunity against pulmonary phthisis is less absolute but is highly demonstrative with a morbidity rate among persons vaccinated with BCG as compared with those not vaccinated, varying from 1 : 3 to 1 : 5. BCG vaccination may be carried out on anergic persons whatever the age but is indicated particularly for persons between the ages of 13 and 25, because of the lesser resistance of these persons to tuberculous infection. Vaccination against tuberculosis is imperative in anergic persons who are exposed frequently to Koch's bacillus in their families or in their occupation. Vaccination against tuberculosis does not exclude other current prophylactic measures.

**Tuberculous Bovine Infection.**—Wissler and Meister report on 65 cases of tuberculosis of bones and joints in children admitted to the sanatorium in Davos Platz, Switzerland. Thirty-seven of these had definite pulmonary tuberculosis in the sense of a primary complex; 5 had doubtful pulmonary tuberculosis; calcified mesenteric lymph nodes were present in 7 patients; 4 presented tuberculous cervical lymphoma, and in 12 patients the localization of the primary complex was not determined. Bovine infection may be conveyed to man almost exclusively by food, leading to primary foci in the intestine or in the oral cavity. Cervical lymphoma may be considered as the clinical manifestation of primary infection of the oral cavity, and tuberculous mesenteric lymph nodes may be considered as the clinical manifestation of primary intestinal infection. Bovine infection was responsible for 11 cases in the authors' series. Nineteen patients had tuberculous spondylitis; an additional 19 had coxitis; 14 had gonitis, and 13 presented various localizations. Permanent damage in the form of ankylosis may be expected in 7 of the 11 cases. Bovine infection plays an important part even among the limited number of patients in a children's sanatorium.

*Syndrome of Pulmonary Hyperventilation. C. Jiménez Díaz.—p. 15.
*Penicillin Treatment as Test for Differential Diagnosis of Abacteric Endocarditis Lenta and of Certain Forms of Rheumatic Fever. F. De A. Estapé.—p. 32.

**Syndrome of Pulmonary Hyperventilation.**—Jiménez Díaz calls attention to the clinical significance of permanent spontaneous pulmonary hyperventilation in normal persons as causative of the effort syndrome. The syndrome is more frequent in young adults and is more frequent in men than in women. It has its origin in a constitutional sympathetic dystonia. It is aggravated by emotion, changes of environmental temperature and physical effort. Alkalosis ensues with consequent cephalic and peripheral anoxia, various metabolic disorders, hypotension and crises manifested by anguish, abdominal vagal disorders, precordial pain, tachycardia, fainting, dizziness, humming noises, cold perspiration, formication and paresthesia of the limbs. Differential diagnosis between the syndrome of pulmonary hyperventilation and the so-called effort syndrome in patients with heart disease or with neurosis is confirmed by provoking pulmonary hyperventilation of two or three minutes' duration, which results in the production of the acute symptoms. The preventive treatment consists in training the patient to control his emotions. Sedatives, intravenous injections of calcium, an acid diet and training the patient to breath with abdominal muscles are of some value. During the acute attack the patient should be made to inhale a gaseous mixture surcharged with carbon dioxide.

**Penicillin as Test for Diagnosis of Endocarditis Lenta.**—Estapé reports 3 cases of endocarditis lenta. Subacute bacterial endocarditis may exist in the presence of negative blood cultures. The differential diagnosis of true subacute endocarditis with negative blood cultures is at times difficult to make. Penicillin therapy in adequate doses and for sufficient duration constitutes the best method of arriving at a differential diagnosis. When the response is nil or is sluggish, the doses can be increased and the period of treatment extended to five weeks. In bacterial endocarditis four or five weeks is the minimum necessary time to check the infection. Penicillin is effective in subacute endocarditis with negative blood cultures. It is only in subacute abacterial pseudoendocarditis and in subacute rheumatism that penicillin is ineffective. In cases of erroneously diagnosed rheumatic fever with positive penicillin therapy, bacterial endocarditis of unknown origin is most likely present.

*Neurologic Symptoms in Patients with Gastroduodenal Ulcers. J. Warter and A. Fitzenkam.—p. 43.
*Treatment of Parotitic Orchitis by Infiltration of Lumbar Sympathetic Nerve. J. Morin.—p. 46.
New Encephalosurgical Method. Chemical Surgery of Nerves. M. Lopez Esnaurrizar.—p. 49.
Treatment of Burns. R. Krafft.—p. 51.

**Neurologic Symptoms in Gastroduodenal Ulcers.**—Warter and Fitzenkam report 72 patients with gastroduodenal ulcers demonstrated by roentgenologic study and in 41 by surgical intervention. The patients presented neurologic symptoms of vestibular type. Sixty-eight (more than 90 per cent) had disturbances of equilibrium manifested by a spontaneous deviation of the stretched out right arm. In all 72 patients the disturbance of the equilibrium was demonstrated by the caloric test. The subjective insensibility of the patients to the caloric test and the absence of vertigo in nearly all patients is emphasized. Four patients presented loss of the vestibular cross reflex; only 2 of the 72 patients presented spontaneous nystagmus. Hypoesthesia of the trigeminus was observed in 7 patients. Hemifacial paresis was observed in 2, and 2 presented disturbances of the periosteal and tendon reflexes. These symptoms arise from the cerebral trunk, particularly from its bulbar portion. They are characteristic for ulcers and are not associated with other digestive, gastrointestinal, hepatobiliary or pancreatic disturbances. They are not of diagnostic value, but they complete the description of the gastroduodenal ulcer as a condition which still requires clarification.

**Treatment of Parotitic Orchitis.**—Morin treated 6 men with parotitic orchitis by infiltration of the lumbar sympathetic nerve with 10 to 20 cc. of a 1 per cent solution of procaine hydrochloride. Within three minutes the patients experienced a sensation of heat in the lower extremities at the level of the testicle, which transformed the painful distension into numbness. Within a short time the pain had disappeared completely and permanently in 4 patients. In 2 patients the pain recurred but was attenuated. Distal manifestations, such as headache, thoracic constriction and vomiting, subsided, and the patients were able to sleep. The effect on the temperature is doubtful, since there was a rise of temperature within two to three days after the first infiltration. Defervescence occurred within three days whether or not the patients were treated by infiltration. The size of the testicle decreased, but a *temporary increase* was observed after infiltration in 1 patient. The course of the orchitis does not seem to be shortened by the treatment. Atrophy of the testicle resulted in 2 of the cases. Infiltration of the sympathetic nerve with procaine hydrochloride is recommended for the alleviation of pain in orchitis.

### Wiener klinische Wochenschrift, Vienna

Relational Pathology as Basis of Therapeutic Thinking. Commemorating the Death of Gustav Rickers. J. Riese.—p. 161.
*Treatment of Diabetes Insipidus with Strong Analeptics. W. Falta and Hedwig Titze.—p. 164.
Treatment of Local Acute Suppurative Processes with Penicillin. R. Demel.—p. 169.

**Analeptics in Diabetes Insipidus.**—Falta and Titze report 1 case of diabetes mellitus and diabetes insipidus in a man aged 46. The diabetes mellitus was characterized by the instability of the metabolic condition with variations in the insulin requirement apparently caused by changes in the conditions of excitation in the vegetative centers of the diencephalon. The term "rocker" has been used for this type of a diabetic patient. Irradiation of the area of the hypophysis with roentgen rays caused considerable increase in the excretion of sugar but did not affect the excretion of urine. The diabetes insipidus was characterized by increase in the amount of urine up to 20 liters per day. The hyperexcretion of urine was reduced only temporarily by the implantation of two calf hypophyses into the abdominal skin of the patient. A slight reduction of the amount of urine resulted from the administration of diencephalic narcotics such as monosodium diethylbarbiturate and cyclohexenyl ethyl barbituric acid. Chloral hydrate and pituitrin proved ineffective. The hyperexcretion of urine was reduced to about 7 liters per day by six intravenous injections of 20 cc. of 20 per cent alcohol daily or by 100 cc. of 40 per cent alcohol administered by mouth. Purified vasopressin (tonephin) was the most effective drug in reducing the hyperexcretion of urine, but was not available in sufficient amounts. Desoxyephedrine (pervitin®), 2 to 3 tablets of 0.003 Gm. for two days and 5 tablets for two additional days, reduced the amount of urine to 12 liters per day. This amount of urine was maintained by the administration of 2 tablets of this drug three times for seven days. The amount of urine was reduced to 8 liters within four days by the subcutaneous administration of 0.05 Gm. of phenyl methylamino hydroxy propane (ephetonin®) given three times. Cocaine combined with caffeine exerted a strong antidiuretic effect, but it could not be decided which of the two drugs was responsible for the effect. Two types of diabetes insipidus exist, one resulting from vasopressin deficiency or insufficiency of the supraopticohypophyseal tracts, which may be compensated by the intramuscular or subcutaneous administration of purified vasopressin; the other results from the inhibition of the function of the anatomically normal posterior lobe of the hypophysis, or the normal supraopticohypophyseal tracts by higher centers localized in the thalamus or hypothalamus. This inhibition may be removed by the administration of alcohol or strong analeptics.

# Book Notices

**Obstetrics in General Practice.** By J. P. Greenhill, B.S., M.D., F.A.C.S., Professor of Gynecology, Cook County Graduate School of Medicine, Chicago. Fourth edition. Cloth. Price, $5.50. Pp. 468, with 108 illustrations. Year Book Publishers, Inc., 304 S. Dearborn St., Chicago 4, 1948.

Four editions of this book have appeared within eight years. By judicious limitation of the subject matter to those aspects of obstetrics which are of direct practical importance, the author has been able to encompass in a volume which is about one quarter the size of our standard textbooks, about all the information which the general practitioner should necessarily possess. Moreover, the common complications are discussed in sufficient detail that he should rarely find it necessary to consult any of the larger works on strictly clinical issues. As a matter of fact, even in those textbooks, he will not often find practical advice provided in greater abundance, or with greater sanity, than in this relatively small manual.

The new edition incorporates all essential new knowledge which is of clinical importance. The section on the troublesome Rh problem has been rewritten and brought up to date. The uses of penicillin and streptomycin in obstetrics, including a detailed consideration of the employment of the former in syphilis, are fully covered. The fifteen page section on placenta previa has been revised in the light of modern trends, and Braxton Hicks version deleted as a recommended method. As in previous editions, safety is emphasized as the paramount objective. The illustrations are attractive and informative, while the small, light format lends itself to easy handling.

General practitioners will find this book full of concise, practical information, and they would do well to read it and take its teachings to heart. If a great many would do so, our maternal and fetal mortality rates would be lower.

**The American Academy of Orthopaedic Surgeons Presents Lectures on Regional Orthopaedic Surgery and Fundamental Orthopaedic Problems.** Selected from the Instructional Courses of the Thirteenth Annual Assembly, Chicago, January 19-23, 1946. Edited by James E. M. Thomson, M.D., Chairman of the Instructional Section. Cloth. Price, $6. Pp. 249, with illustrations. J. W. Edwards, 300 John St., Ann Arbor, Mich., 1947.

The publication of selected subjects from the 1946 instructional courses on regional orthopedic surgery and fundamental orthopedic problems is of commendable interest to the orthopedic surgeon, the general surgeon and the medical practitioner. The lecturers are all senior orthopedic surgeons of experience and ability.

Among the numerous subjects dealt with, particular emphasis has been placed on the shoulder, hip and foot-ankle region. Excellent papers on the anatomy of the region concerned, which are not too detailed but adequate for the problems considered, open each series. The symptoms, pathology and diagnosis of the frequent causes of disability affecting these large joints are capably and thoroughly discussed. The most comprehensive are those dealing with the shoulder, especially stiffness, pain and moderate injury; and this section is of inestimable value to the young specialist and the general man. It is regrettable that papers dealing with the costoclavicular syndrome and ruptured intervertebral disk lesion of the cervical area have been omitted.

Excellent advice is contained in the section dealing with the principles of fracture management, as well as the problem of the clubfoot. The symposium on degenerative hip disease is comprehensive and instructive. The section dealing with the roentgenologic examination of the spine is timely, considering the tremendous interest that exists in low back pain. Some of the roentgenograms could have been more clear; even lining the vertebral bodies would have increased their usefulness. The two short articles dealing with anterior poliomyelitis are instructive, though one could have wished for additional information on this difficult subject.

The cases presented for discussion, which are included at the end of the book, are excellent, but they could well be made fuller and possibly more cases included in an ensuing year.

The American Academy of Orthopedic Surgeons is to be commended for their successful effort each year in holding an instructional course of such merit as these lectures demonstrate.

**Diabetes and Its Treatment.** By Joseph H. Barach, M.D., F.A.C.P., Associate Professor of Medicine, University of Pittsburgh, Pittsburgh, Pa. Cloth. Price, $10. Pp. 326, with 73 illustrations. Oxford University Press, 114 5th Ave., New York 11, 1949.

Dr. Barach's medical textbook on diabetes is a newcomer. The author is an experienced clinician and is now chairman of the useful Metabolism and Endocrinology Study Section of the Research Grants Division of the United States Public Health Service. His book is written for the benefit of the medical practitioner who does not see much of the disease. Its style is similar to that used by Dr. Joslin in his well known textbook, especially in that the statistical method of reporting on various phases of the disease is used freely. Barach's own cases ase used in the assembling of these data, for the most part.

The book begins with a review of the history of the accumulation of knowledge about the disease. Descriptions of developments follow one another with little effort on the part of the author to distinguish between major and minor discoveries. The etiologic and incidence background follows the historical section, with statistical summaries predominating.

Chapters on diagnosis, clinical and laboratory, are followed by discussions of "clinical pathology," diseases of the extremities and their treatment, and the use of surgical procedures in the diabetic patient. Diabetic acidosis and coma and pregnancy in the diabetic patient are discussed thoroughly in separate sections. The treatment of acidosis is given in decidedly empiric fashion.

Barach's thorough study of nutrition and growth in childhood are revealed in the extensive data given in the childhood section. Detailed descriptions are given of various factors employed in selection of diet and maintenance of proper nutrition, instruction of the patient and prevention of diabetes by such methods as are available. A chapter on the use of insulin seems inadequate in view of its importance in treatment and the complexities in its use. The final third of the book contains a variety of over three hundred different quantitative diets suitable for every conceivable circumstance, showing in each case the number of grams of food ordered for each meal, their equivalents in ordinary household measures and the fuel values for each meal and totals for the day. These are accompanied by several pages of recipes, conversion tables, tables of caloric values and ideal weights, and instructions for diet calculations.

As the organization of Dr. Barach's book is not very logical, it will serve better as a reference book for practical detail than as one which will train the physician in fundamental understanding. Some of its explanations of mechanisms are scientifically unsound. Its interpretations are those of the practical clinician rather than those of the impartial and well informed physiologist or biochemist. For example, the lower incidence of diabetes in the South, in rural areas and in China is attributed by the author to differences in diet and other conditions of living in these areas, whereas other possible reasons are obvious. The differences could just as well be explained by deficient diagnosis and reporting in these areas, as suggested by Joslin's survey in Arizona.

Other random criticisms are applicable. The discussion of endocrine relationships in diabetes is not well organized and is unconvincing. A good deal of pertinent physiologic evidence is omitted. The author's instructions that insulin should be omitted or reduced in illness or prior to operation seem dangerous. The author's tolerance for higher sugar levels in mild diabetes is out of line with modern views that much is to be gained by good control in patients who are so easy to manage. The arbitrary prescription, oft repeated, of 1 unit of insulin for every 2 Gm. of glucose in the urine or diet fails to allow for sharp individual variations in insulin sensitivity. The decisive value of insulins with intermediate action and their use in practice is not sufficiently appreciated or covered in a book written in 1949.

This book might be described succinctly as a useful encyclopedia of empiric information regarding diabetes, written in a simple, uncritical style, with moderate views which attempt to compromise in controversial matters, sometimes at the expense of clarity and accuracy.

**Surgical Technique and Principles of Operative Surgery.** By A. V. Partipilo, M.D., F.A.C.S., Associate Clinical Professor of Surgery, the Stritch School of Medicine of Loyola University, Chicago. Foreword by Alton Ochsner, M.D., F.A.C.S., William Henderson, Professor and Director of the Department of Surgery, The Tulane University School of Medicine, New Orleans. Original illustrations by W. C. Shepard and Hooker Goodwin. Fourth edition. Cloth. Price, $15. Pp. 676, with 541 illustrations. Lea & Febiger, 600 S. Washington Sq., Philadelphia 6, 1949.

Although the previous editions of this work were considered excellent, this edition is an improvement over the others. Most of the book is the work of the author, but a number of excellent chapters were contributed by collaborators who are practicing surgeons of wide experience and actively engaged in teaching. The book covers the surgery of hernia, stomach and intestines, gallbladder, duodenum, pancreas, colon and rectum, breast, thyroid, peripheral vascular diseases and facial injuries. Several chapters are devoted to the general principles of surgery, including a historical review of the sciences of physiology, pathology and anatomy, and the value of these to the surgeon; a discussion of incisions, hemostasis and wound healing. Various methods of knot tying are described and illustrated minutely. The newer surgical procedures, such as vagus resection, surgery of the pancreas, colon and rectum, biliary tract, heart and peripheral vascular system are included and discussed in detail.

Where indicated, each chapter includes a review of surgical anatomy and a discussion of pertinent pathologic and physiologic aspects of each subject. The importance of diagnosis, indication for operation and preoperative and postoperative treatment is emphasized. Technical steps of each operative procedure are described in detail and profusely illustrated. The significance of atraumatic technic, careful hemostasis and gentle handling of tissues, which are essential in any operative procedure, is particularly stressed.

The book is well written. It is clear and concise. The material is up to date, practical and logically presented. The illustrations are numerous and of excellent quality. They combine anatomic and technical detail with scientific accuracy, and greatly enhance the value of the text.

The book is a distinct addition to the library of every student and practitioner of medicine.

**Recent Advances in Respiratory Tuberculosis.** By Frederick Heaf, M.A., M.D., F.R.C.P., Senior Medical Officer, London County Council, and N. Lloyd Rusby, M.A., D.M., F.R.C.P., Assistant Physician, The London Hospital, London, England. Fourth edition. Cloth. Price, $5.50; 21 s. Pp. 290, with illustrations. The Blakiston Company, 1012 Walnut St., Philadelphia 5; J. & A. Churchill, Ltd., 104 Gloucester Place, Portman Sq., London, W.1, 1948.

This book is a revision of a book under the authorship of L. S. T. Burrell of London, who was the author of the first three editions. The present authors prepared the fourth edition in order to describe the notable advances in respiratory tuberculosis since the previous author's death. They feel that the outstanding single development in the management of tuberculosis in the last decade has been realization of the important part which environment and social circumstances play in the successful control of tuberculosis.

There are several excellent chapters on the subject of resistance and infection. Much of the material presented is quoted from many reliable sources from various countries.

The present conception of the value of BCG in immunization of whole populations is discussed. The authors feel that the ideal protection has not been found but that statistical studies warrant the belief that attenuated tubercle bacilli must be nonvirulent, as injection of virulent tubercle bacilli is too risky. The statistical studies presented do not seem to warrant the assumption that BCG is a virulent form of the tubercle bacilli.

Mass radiography has been the most modern innovation in the campaign against tuberculosis. This statement is shared by tuberculosis specialists throughout the world. Considerable attention is given to the technic of roentgen ray studies, and one sentence in the discussion of this subject warrants repetition: "Progressive improvements in apparatus have increased the simplicity of operation, but no x-ray plant can eliminate errors due to wrong positioning, dusty screens, incorrect penetration, bad developing. . . ." Tomography is discussed, and the authors suggest that no well regulated hospital or sanatorium should be without a tomograph. Attention is given to the anxiety states of the tuberculous in relation to symptoms, and the authors suggest that complete physical and roentgen ray studies should be made in all cases to establish the exact state of the lungs.

A significant discussion is presented on the relationship of tuberculosis and pregnancy, and from much quoted material from various countries the authors suggest that termination of pregnancy is not necessary in well controlled cases of tuberculosis in sanatoriums. Collapse therapy is urged in all cases of tuberculosis where pregnancy is present.

Nearly all the new surgical procedures for collapse and relaxation of the lung are described rather briefly; much more space is given to pneumothorax. Lobectomy and pneumonectomy are also mentioned. The authors state that there is a place for such radical surgery in only a few cases.

Socialized medicine from the British point of view is described in several chapters at the end of the book. The government has innumerable rules and regulations to cover diagnosis, treatment and the length of stay in the hospital or sanatorium. This type of control would certainly not appeal to American tuberculosis specialists. The British government also gives a minimal living expense to the family while the breadwinner is under treatment. There are only six reproductions of roentgenograms in the book.

This work is a good review of the present conception of tuberculosis and also of the present mode of treatment, and is recommended to students, public health nurses and general practitioners.

**Recent Progress in Hormone Research: The Proceedings of the Laurentian Hormone Conference (1947). Volume III.** Edited by Gregory Pincus. Cloth. Price, $7.80. Pp. 378, with illustrations. Academic Press, Inc., 125 E. 23rd St., New York 10, 1948.

Dr. Gregory Pincus has again performed a masterly task in assembling and editing the proceedings of the Laurentian Hormone Conference. As in previous conferences, the emphasis was on the chemistry and physiologic actions of the various steroid hormones and their derivatives. An excellent discussion of the relation of the doisynolic acids to the various sex hormones is presented by Dr. K. Miescher. Only recently have chemical methods been available for a complete study of the relationship of these acids to the naturally occurring sex steroids.

Drs. Seymour Lieberman and Konrad Dobriner present a highly technical, but nonetheless interesting, discussion of steroid excretion in health and disease. The difficulties encountered in attempting quantitative studies of steroid excretion appear to be diminishing; Dr. Dobriner's group is making great strides in elucidating the alterations in the pattern of steroid excretion in various metabolic and endocrine disorders. A presentation by Dr. Harold L. Mason on the metabolism of adrenal hormones extends the paper of Drs. Lieberman and Dobriner into a field which is of rapidly growing importance.

Two papers on chemical cytology by Dr. Edward W. Dempsey and by Dr. C. P. Leblond summarize the progress made in this area, in which the chemist and the pathologist join hands in an attempt to unlock the mysteries of intracellular metabolism.

The biochemistry of the growth hormone is discussed by Dr. Choh Hao Li and Dr. Herbert M. Evans, the former having produced the first pure preparation and the latter having discovered this pituitary hormone.

The physiology of the testis is discussed in four papers, and, as usual, a great deal of the discussion centers around hypogonadism and the "male climacteric." The papers by Dr. Warren O. Nelson and Dr. Carl G. Heller and by Dr. James B. Hamilton serve to clarify this field, which has been well discussed in previous conferences.

For the first time, the relationship of hormones to hypertension receives exhaustive discussion. The relationship of the renal pressor system to humoral influences is presented by Dr. A. C. Corcoran. The relationship of renin, angiotonin and the various enzyme systems with specificity for these substances to other pressor systems within the body is reviewed. Dr. Hans Selye discusses hypertension as a disease of adaptation, a point of view gaining adherence by an increasing number of workers in this field.

Of great value to the student of endocrinology are the delightful and informative discussions given at the end of each paper. The excellent editing of these discussions preserves their informality but makes them a valuable addition to the formal text.

The proceedings of these conferences, of which this is the third volume, should be in the library of every person seriously interested in the fundamental aspects of endocrinology.

**Lehrbuch der Geburtshilfe.** Von Prof. Dr. med. Heinrich Martius, Direktor der Universitäts-Frauenklinik Göttingen. Unter Mitarbeit von Professor Dr. med. Werner Bickenbach, Professor Dr. med. Kurt Nordmeyer und Käthe Droysenals Zeichnerin. Erster Teil: Physiologie Zweiter Teil: Pathologie. [Reprint of 1943 edition]. Boards. Pp. 568; 569-1176, with 1025 illustrations. Georg Thieme, Diemershaldenstrasse 47; Stuttgart-O, 1948.

In the first volume of the *Lehrbuch* the author takes up the physiology of pregnancy, labor, the puerperium and lactation, multiple births, the healthy newborn infant, prenatal care and nutrition of the mother. In the second volume he discusses the pathology of pregnancy, dystocia in labor, the pathology of the puerperium and diseases of the newborn. There are 539 illustrations in the first volume and 486 in the second. Many illustrations are in color and nearly all of them are clear and instructive. However, the reproductions of the roentgenograms are poor. Several illustrations could have been omitted without detriment to the book. The Crede maneuver for separation and delivery of the placenta should not be described or illustrated because, as the author himself admits, the maneuver can do harm. Likewise, the illustrations devoted to packing the uterus for the control of postpartum hemorrhage should be deleted because uterine tamponade has wisely been given up by most obstetricians. The author should omit from the next edition the illustrations of the Gylicki and Gauss pelvimeters for measuring the pelvic inlet because this procedure is not only painful but is entirely unreliable. These instruments should be relegated to the past with the many similar instruments once considered useful. There is no point in demonstrating a colored photomicrograph of a kidney from a woman who died of eclampsia because this lesion is not pathognomonic of eclampsia. In several of the illustrations, ungloved hands are shown, as for packing the uterus. The reviewer disagrees with the author that chloroform is the best anesthetic to use in eclampsia. The safest anesthetic is direct infiltration and the next safest is low spinal.

In spite of these criticisms, the book is excellent. Throughout both volumes, it is apparent that the author has had extensive experience in clinical obstetrics. The advice given is conservative and to the point. Assistance was given by Werner Bickenbach and Kurt Nordmeyer, and the illustrations were drawn by Kaethe Droysen. All these as well as the publishers are to be commended for having produced a good book.

**Practical Spectroscopy.** By George R. Harrison, Ph.D., Sc.D., Professor of Physics; Richard C. Lord, Ph.D., Associate Professor of Chemistry, and John R. Loofbourow, Sc.D., Professor of Biophysics, of the Spectroscopy Laboratory, Massachusetts Institute of Technology, Cambridge, Massachusetts. Cloth. Price, $6.65. Pp. 605, with illustrations. Prentice-Hall, Inc., 70 Fifth Ave., New York 11, 1948.

The authors have presented a comprehensive discussion of the status and possibilities of experimental spectroscopy as it exists today. This includes applications in the fields of physics, chemistry and biology. Emission spectroscopy is treated in detail, including discussions of equipment, facilities and technics. Several methods, such as fractional distillation and the moving plate method especially applicable to the examination of biologic mixtures, are discussed. Absorption spectrophotometry in the ultraviolet, visible and infra-red regions is discussed in less detail. However, these sections constitute one of the best presentations on this field available today in book form. Currently, there is a great increase in the use of spectrophotometry in clinics and pharmacology laboratories. The chapters relating to this subject are recommended reading for all connected with such laboratories.

In discussing a field so widespread as spectroscopy, it is impossible to present an exhaustive description of each technic. An extensive bibliography is given, so that references to more detailed discussions are almost always presented.

**Athletic Injuries: Prevention, Diagnosis and Treatment.** By Augustus Thorndike, M.D., Chief Surgeon to the Department of Hygiene, and to the Harvard Athletic Association, Harvard University, Cambridge, Massachusetts. Third edition. Fabrikoid. Price, $3.75. Pp. 243, with 114 illustrations. Lea & Febiger, 600 S. Washington Sq., Philadelphia 6, 1948.

This book is well written and well edited. There is one error in the transposition of titles in figures 80 and 81 which is obvious and a typographical error in spelling on page 210. The book gives a clear, concise picture of the diagnosis and treatment of athletic injuries at Harvard University.

Two chapters on "Physical Fitness" and "Physical Fatigue" give sound scientific discourses on these subjects. The author claims that there is no such thing as "the athletic heart." He advocates a break in the monotonous routine of daily practice in order to obviate "mental fatigue."

The author believes that the prevention of injuries is important. This is done by special exercises for the knee and shoulder joints, as well as for other muscles and joints. A sprained ankle always remains a weakened joint, he claims, but he does not believe in routine strapping of ankle joints. "Once a sprain always a sprain."

The protective pads and covering should be regulated uniformly so that they will not injure opposing players.

Thorndike then takes up the different injuries individually in chapters headed "Sprains," "Strains," "Contusions," "Fractures and Dislocations," "Internal Injuries," etc. He lays stress on the early use of cold for many. His statistics compare favorably with those of Lloyd, Deaver and Eastwood and of Hobart, and the knee again leads all other parts of the body in number and percentage of injuries. He lays great stress on muscle injuries, which other authors do not find so frequent or serious.

In mentioning knees the author emphasizes a careful examination. Over half of his knee injuries were sprains, and he claims that he has had only six internal derangements (meniscus damage) in 423 cases since using the Duke-Simpson strapping. This ingenious but complicated strapping is employed in all athletes with a history of earlier sprain. In fifteen years' experience among 16,000 athletes only thirty-three semilunar cartilage injuries were found, necessitating only six operations. However, he does recognize what he calls "inherited school boy knee" and refuses such persons the privilege of playing football. Many of these injuries can be cured by operation and exercises.

**The Achievements of BCG Vaccination, Illustrated by Material at the Tuberculosis Department of the Oslo Public Health Service.** By Gerhard Hertzberg, Medical Officer. Paper. Price, 15 Norwegian kroner. Pp. 312. Johan Grundt Tanum-Forlag, Kr. Augustsgate 7a, Oslo, 1948.

This report of a study of the results of BCG vaccination was culled from the records of the Tuberculosis Department of the Oslo Public Health Service. Of 18,496 persons vaccinated, only a portion were available for analysis. Matched with the vaccinated were 1,832 nonvaccinated persons, who served as controls.

The Norwegian law of 1942 made convertors (persons whose tuberculin skin reactions changed from negative to positive) reportable. In December 1947, BCG was made compulsory for certain groups in Norway. In this material BCG seemed to eliminate such primary tuberculous lesions as erythema nodosum and tuberculosum, hilar adenitis and roentgenologic primary foci in the lungs. This seemed to be more evident in males than in females.

A comparison of the vaccinated and the controls revealed a difference in the rate in the two groups, as follows: group A, true primary tuberculosis of the lungs and hilar lymph nodes, with or without skin manifestations, 1 to 137; group B, tuberculosis of glands, skin and soft tissues, 1 to 6; group C, pleuritis, pulmonary infiltration, and tuberculosis of the bones, joints and eyes, 1 to 9, and group D, tuberculous meningitis, miliary tuberculosis and destructive pulmonary tuberculosis, 1 to 27.

For all forms of tuberculosis, the difference in the rate between the vaccinated and the controls was 1 to 23. The difference in death rate from tuberculosis was 1 to 45. The author states, "The value of such rates will be very limited from the statistical point of view, but they bring out points of considerable interest."

Evidence is presented that the local reaction following vaccination determines to a great extent the subsequent tuberculin reaction. The degree of the tuberculin reaction determines the duration of the vaccination allergy, but is not related to resistance on superinfection.

Reinfection tuberculosis is considered in persons in whom the von Pirquet reaction increases at least 2 mm. and in whom the Mantoux test with 1 mg. of old tuberculin increases by 20 mm. The validity of these criteria for reinfection will not be argued, but since they represent but a small fraction of the actual state of reinfection, the use of these observations may be misleading.

In a study of some 900 cases by the reviewer, three physicians read the tuberculin reactions in control and vaccinated children up to 18 years of age. There was no notable difference in the type of reactions of the two groups.

The author prefers the intradermal to the multiple puncture method, his comparison being made on 1,749 persons vaccinated by the intracutaneous method against 51 by the multiple puncture method. This would hardly seem a fair comparison, especially since the author states, "I have no proof that the other factors mentioned (contact with tuberculosis, etc.) are uniformly distributed in the two groups."

The data presented are unequivocal concerning the harmlessness of BCG vaccination. The evidence is most impressive regarding the efficacy of BCG vaccination, both in regard to morbidity and mortality from tuberculosis. Both physicians and statisticians will find this book of great interest.

**Modern Trends in Psychological Medicine, 1948.** Edited by Noel G. Harris, M.D., F.R.C.P., D.P.M., Physician for Psychological Medicine, Middlesex Hospital, London. Cloth. Price, $10. Pp. 450, with 25 illustrations. Paul B. Hoeber, Inc., Medical Book Department of Harper & Brothers, 49 E. 33d St., New York 16, 1948.

In nineteen comprehensive chapters here is a presentation of the present status of psychiatry and what we may expect of it. The editor and the several authors are outstanding. Only one chapter deals with a nosologic group; that one is on psychopathic personality, and it leaves something to be desired in its failure to recognize some of the psychodynamic contributions of Karpman and Maughs, for instance. The other chapters deal with psychosomatic medicine, the physiology of emotions, causative factors in mental disturbances, electrophysiology, diagnostic measures, child guidance, marriage and family life, group therapy, psychotherapy, physical treatment, personnel selection, rehabilitation, mental hygiene in industry and the relation of psychiatric medicine to world affairs. The approach throughout is broad; the doctrinaire attitude is conspicuous by its absence.

The chapters are carefully prepared, and each is followed by a bibliography. The printing is excellent, and there are twenty-five illustrations. The volume is an excellent presentation of the present state and prospects of a specialty which is developing rapidly.

**Fractures and Orthopaedic Surgery for Nurses and Masseuses.** By Arthur Naylor, Ch.M., M.B., M.Sc., Orthopaedic Surgeon, Bradford Municipal General (St. Luke's) Hospital, Bradford, England. Foreword by Ernest Finch, M.D., M.S., F.R.C.S., Consulting Surgeon, Royal Infirmary and Hospital, Sheffield, England. Second edition. Cloth. Price, $5. Pp. 296, with 251 illustrations. The Williams & Wilkins Co., Mt. Royal & Guilford Aves., Baltimore 2, 1948.

It is to help nurses and masseuses to understand and follow the principles of orthopedics that Mr. Naylor has written this book. He shows the nurse how the principles are applied in orthopedic surgery and as a supplement to her lectures in surgery. The introduction of penicillin has necessitated alterations in the text of this, the second edition.

The success of orthopedic surgery is largely dependent on the knowledge, skill and care of the nurses and physical therapists to whom after-care and treatment are delegated. The student nurse has often only a bare minimum of instruction in orthopedic surgery; yet approximately one fifth of her surgical work will be concerned with this branch of surgery.

This book will be useful to registered nurses and to those who intend to undertake or are engaged in nursing in orthopedic wards, or at special hospitals or in the public health services. It should be of value to physical therapists as a general outline of the clinical and surgical aspects of orthopedic conditions

The author discusses orthopedic apparatus; operating room technic; methods of correction of deformity; amputations; fractures and dislocations; diseases of bones and joints, diseases of the soft tissues; congenital deformities; diseases of the epiphyses; peripheral vascular lesions; orthopedic surgery of paralysis, and diseases of the spine and foot.

**Poisons: Their Isolation and Identification.** By Frank Banford, B.Sc. Revised by C. P. Stewart, M.Sc., Ph.D., Senior Biochemist, Royal Infirmary, Edinburgh. With a foreword by Professor Sydney Smith, C. B. E., M.D., F.R.C.P., Regius Professor of Forensic Medicine, University of Edinburgh, Edinburgh. Second edition. Cloth. Price, $5. Pp. 304, with 23 illustrations. The Blakiston Co., 1012 Walnut St., Philadelphia 5, 1947.

The book is offered as a practical guide for the chemical analysis of various poisons. As a laboratory manual for the qualitative analysis of these poisons, it goes into much detail with respect to technic and appears to be written from first hand experience.

The poisons are classified into various groups which are determined by the methods used for their isolation and separation. The author devotes a chapter or two to the discussion of each group and the poisons it contains. The groups are the volatile poisons—that is, those which distil with a current of steam—the metallic poisons, the acid, alkali or irritating salt type, the nonvolatile basic organic poisons, the nonvolatile nonbasic organic poisons and a miscellaneous group which require various special methods for isolation.

A systematic scheme is presented for the identification of alkaloids which is based on their reaction with various precipitation and color reagents. A chapter is also devoted to a systematic procedure for the separation and identification of various nonbasic organic poisons.

The book, although intended as a laboratory manual, is written in a style which makes for easy and interesting reading. It contains numerous helps and suggestions for the practicing toxicologist, such as a brief outline of postmortem signs, as indications of the cause of poisoning.

**Nutrition and Physical Fitness.** By L. Jean Bogert, Ph.D., Instructor in Experimental Medicine, Yale Medical School, New Haven, Conn. Fifth edition. Cloth. Price, $4.25. Pp. 610, with 97 illustrations. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London W.C. 2, 1949.

The author states that the purpose of this book is threefold: (1) to gather into a single volume information useful in meeting everyday nutritional problems, which has been gleaned from the fields of food composition and economics, the chemistry and physiology of body processes, dietetics and medicine; (2) to make this information available to a comparatively large group by presenting it in such simple language as to be understandable to those with no previous knowledge of chemistry, and (3) to point out, in every instance possible, how such knowledge may be utilized for preventing ill health and promoting a high degree of physical fitness.

Part I includes a discussion of sugars, starches, proteins, fats, milk and milk products, fruits and vegetables. The different varieties of these food groups, their chemical properties and their place in the diet are presented in detail.

Part II is concerned with the nutritional needs of the body. There seems to be some burdensome repetition between these two sections. For example, in part I complete and incomplete proteins are elaborated on at some length. This is repeated in part II. The book might seem better organized if the order of these two sections were reversed.

In the text tables are included which give the approximate ascorbic acid, thiamine and vitamin A content of typical foods in terms of average servings. To be consistent, it would be logical to prepare similar tables for the other important nutrients. This type of information is more practical than tables of percentage composition.

Part III is a section on physiology, dealing chiefly with digestion, metabolism and excretion. Part IV contains helpful facts about meal planning, food economics, food fads and fancies, and recent trends in our dietary habits. The last chapters are on diet for special conditions such as obesity, underweight and pregnancy. The dietary needs during childhood are also presented. The appendix includes a table of food values, tables of ideal heights and weights for adults and children and a list of

100-calory portions of common foods, which material is becoming less popular with nutritionists because it is impractical to use in teaching.

Each chapter concludes with questions and problems for classwork and lists of suggested readings. The textbook can be recommended for use in teaching a college course in nutrition or as a reference book for a course in nutrition for nurses, social workers or teachers. High school teachers of biology or health education would also find practical information in it suitable for integration in their classwork.

**Symposium on Radioiodine July 28-30, 1948.** Brookhaven Conference Report, BNL-C-5. Paper. Price, $1.50. Pp. 114, with 27 illustrations. Brookhaven National Laboratory, Associated Universities, Inc., Upton, L. I., N. Y., [n.d.]

The volume opens with a historical review of the use of iodine in the treatment of diseases of the thyroid and moves rapidly to modern times and the first use of $I^{131}$. The remainder of the volume is divided into sections. These sections correspond to the various component sessions of the symposium.

The first session was on physiology and was opened with an interesting paper on $I^{131}$ as a tracer in thyroid neoplasm. A paper of note in the physiology section is the mechanism of action of antithyroid drugs. In another paper the biologic effect of radiation by radioactive iodine is well considered. The second session was a session on laboratory topics. Several papers of considerable merit are contained herein, notably one on standardization of radioactive iodine and another on calculation of dosage in radioiodine therapy. The third portion of the volume is devoted to the proceedings of the session on hyperthyroidism. In this section most of the progress in the treatment of hyperthyroidism and toxic goiter by $I^{131}$ is outlined. The fourth section of the volume is devoted to pathology and allied topics. Outstanding in this section are papers on histologic types of thyroid carcinoma and their respective abilities to store radioactive $I^{131}$. Several technics of radioautography are outlined in this section and are well worth consulting.

The final section of the volume is devoted to a study of the treatment of carcinoma of the thyroid. In the two papers that comprise this section there are outlined several methods of enhancing the uptake of $I^{131}$ by metastatic thyroid neoplasm.

The volume should be read by everyone who works with radioactive materials, but it could also be consulted profitably by any practicing physician.

**Collateral Circulation (Anatomical Aspects).** By Daniel P. Quiring, Ph.D., Head of the Anatomy Division, Cleveland Clinic Foundation, Cleveland, Ohio. Cloth. Price, $5. Pp. 142, with 61 illustrations, 46 in color by Margaret Holman. Lea & Febiger, 600 S. Washington Sq., Philadelphia 6, 1949.

The author offers a convenient reference book to the chief arterial and venous collateral channels of the human body. Although a brief review is given of the major circulatory pathways as found in standard anatomic textbooks, emphasis is placed on the communicating shunts as demonstrated in original dissections and as gleaned from the literature. The author has correlated in a refreshing, simple fashion material drawn from anatomic, physiologic and clinical sources as it relates to the problem of blood circulation. As such the study should hold wide interest. Easily accessible are the chief cross connections which develop in the vascular system on occlusion of vessels normally responsible for the circulation to a body part. A short historical review is followed by a lengthier note on the development of blood vessels. Embryology and comparative anatomy are drawn on and the author concludes that inheritance and hemodynamic forces incident to blood flow determine the pattern of the vascular tree. Blood goes where it is needed.

A philosophic discussion of the development of collateral pathways follows. Of clinical interest particularly is the differentiation of changes incident to sudden and gradual occlusion of main stems. In the latter situation the collateral circulation depends primarily on the state of the walls of the anastomosing channels and in lesser degree on their number and their diameter, while in sudden occlusion the primary factors are the number and extent of the anastomoses, secondarily the nature of the walls.

The simplified line color diagrams with which the book abounds are of great help in portraying the three dimensional effect incident to these cross connections. This is true in depicting the four major collateral pathways through which blood is returned to the heart from the lower extremities and trunk. Color drawings on skeletal relief are used effectively to demonstrate the by-passes found in head and neck, trunk, shoulder and upper extremity, and lower extremity. A separate section is devoted to cardiac circulation. Of particular merit is the discussion relative to collateral pathways about the carotid arteries, adrenal vessels, vena cava, leg veins, and the important vertebral veins. The integration of this knowledge finds clinical application in understanding the fate of parts following vascular accidents, the dispersion of infections and the metastases of cancer.

This enlightening emphasis on collateral channels warrants attention from the anatomist and physiologist in understanding the basic pattern and function of this circulation, and should be of value to the clinician in the practical application of this knowledge.

**Principles of Health Education Applied.** By Clifford Lee Brownell, Ph.D., Chairman, Health Education and Physical Education Department, Teachers College, Columbia University, New York, N. Y. McGraw-Hill Series in Health Education, Physical Education, and Recreation. Clifford Lee Brownell, Consulting Editor. Cloth. Price, $3.75. Pp. 366, with 16 illustrations. McGraw-Hill Book Company, Inc., 330 W. 42d St., New York 18; Aldwych House, Aldwych, London, W.C. 2, 1949.

Inaugurating a new series in health education, physical education and recreation, this volume is addressed specifically to students of health education and generally to all those with a participating interest in this subject. These, of course, range from teachers through administrative officers to parents and the general public that foots the educational bill.

In most part, Brownell does an excellent job of presenting both sides of the numerous highly debatable phases of health education. However, there is some evidence that there has been insufficient collaboration with the medical profession on some phases of the volume. Specifically, Brownell accepts without reservation the spurious claims based on prejudiced or even deliberately false analyses of World War II draft statistics, and in the face of evidence such as that presented by Freedman or in the Brookings report he writes on page 31 of the "appalling number of young men found unfit for military service" and on page 274 offers a quotation emphasizing the same serious misunderstanding. Although Brownell does offer a rationalization of this situation on page 32, it is considerably less emphatic than his "pro" discussion.

After four chapters of orientation on the general problem of health and health education, the book treats specific subjects such as school organizations for health, health services, education of the handicapped, health and safety instruction and professional preparation for health education. Understandably, there is a strong chapter on the relationships between health education and physical education. This contains adequate recognition of the necessity for proper medical supervision of physical education activities.

Perhaps the only serious omission in the volume is consideration of sex education in relation to health education.

The book is written in a friendly style, and of special value are summaries at the end of each chapter plus lists of questions and problems for discussion as well as selected references. Physicians will find it of interest as a source of helpful background for their contacts with medical aspects of school health education and services.

**Hypnotism Comes of Age: Its Progress from Mesmer to Psychoanalysis.** By Bernard Wolfe and Raymond Rosenthal. Cloth. Price, $3. Pp. 272. The Bobbs-Merrill Co., 724-730 N. Meridian St., Indianapolis 7, 1948.

With the development of hypnonarcosis as an established technic by investigations of psychiatric disturbances during the war, much interest has been aroused in the method. The volume here considered approaches the subject from the special point of view of the psychoanalyst and indicates the manner in which the two technics can be integrated for application. One of the best chapters is entitled "The Layman Asks Some Questions"; this does give authentic replies to most of the questions that arise in the minds of average readers.

**Krebsmetastasen.** Von Dr. med. Hans E. Walther, leitender Arzt der Röntgenabteilung des Schwesternhauses vom roten Kreuz in Zürich. Vorwort von Prof. Dr. H. von Meyenburg, Direktor des Pathologischen Institutes in Zürich. Cloth. Price, 60 Swiss francs; $18. Pp. 560, with 359 illustrations. Benno Schwabe & Co., Klosterberg 27, Basel 10; Imported by Grune & Stratton, Inc., 381 Fourth Ave., New York 16, 1948.

The physician's interest in patients with cancer frequently diminishes in proportion to the spread of cancer from its original site to other organs, because medicine or surgery offers little to relieve metastatic cancer and radiation therapy is at best only palliative. Neoplastic metastases, therefore, are seldom the subject of intensive scientific study.

This book, written in German by a Swiss radiologist, attempts to fill this gap in the medical literature and is based on many years of clinical experience and extensive study of pathologic-anatomic material. Postmortem examinations on 3,433 patients with cancer form the basis for the author's thoughtful monograph. An attempt is made to uncover guiding principles which govern the spread of cancer and thus to facilitate the evaluation of the prognosis in different types of malignant growths.

The book is divided into two main parts. In the general section, the morphologic and biologic qualities of the cancer cells and the grading of malignancies are explained and the author's "malignancy index" described. The latter is determined by adding the continuous extension ($c$) of the tumor, its lymphatic spread ($l$) and its hematogenous ($h$) spread, all of which are arbitrarily evaluated in a relation of 1:2:10 and divided by 100. Therefore, the formula of the "malignancy index" is as follows:

$$M = \frac{c + 2l + 10h}{100}$$

According to the author, the occurrence of metastases follows closely the anatomic design of the blood vascular system and can be predicted if the primary site is known. Conversely, if neoplastic metastases are found in various organs, the site of the primary lesion can usually be assumed with a high degree of certainty. The author is convinced that all metastases to lymph nodes are "regional." They are either "primary," if they are localized in the draining area of the primary tumor, or "secondary," if the tributary organ is invaded by way of the blood system. The author does not accept the theory of lymphatic connections between two different organs. The possibility of "retrograde" lymphatic spread is refuted by the author, and so this controversy is continued. The chapter on diagnostic methods of neoplastic metastases is short, and cytologic methods are discussed. The Papanicolaou stain, chiefly important for the diagnosis of primary lesions, is not mentioned.

In the special section, the frequency of different types of malignant growths in the various organs is described, and growth tendencies and modes of spread analyzed. Statistical evaluations support the author's theories.

The book is well written and offers a wealth of material for thought. It is a fascinating piece of work by an earnest and experienced clinician who expresses his ideas in a convincing manner. Minor differences of opinion as to the frequency of metastases in different organs do not depreciate the value of a readable and highly recommendable work.

***Morfologiczne badania porównawcze nad rola ukladu mezenchymalnego a w szczególności sercowo-naczyńiowego w zapaleniu hiperergicznym i gośćcowym.*** [By] Kazimierz Stojalowski. [Comparative Morphologic Studies on Role of Mesenchymal System and Especially of Cardiovascular System, on Hyperergic and Rheumatic Inflammation.] Poznańskie Towarzystwo Przyjaciól Nauk. Prace Komisji Lekarskiej Tom VI, Zeszyt 1. Paper. Pp. 159, with 15 illustrations. Poznańskie Towarzystwo Przyjaciól Nauk, ul. Sew. Mielżyńskiego 26/27, Posen, 1947.

This monograph deals with the author's microscopic studies of postmortem material of the Pathologic Institute of the University of Poznań (Poland). An attempt is made to bring into correlation the microscopic alterations in rheumatic fever as regards the connective tissue and the circulatory system, and the analogy between rheumatic fever and experimental hyperergic inflammation. Experiments performed by the author represent a modification of Klinge's experiments. The modification consisted in sensitizing rabbits by human rather than horse serum. Serum obtained from a case of acute rheumatic fever and from a case of asthma was injected into the knee joint of a sensitized rabbit. A striking resemblance was noted in the histopathologic alterations in experimental hyperergic inflammation and in those of the rheumatic fever. The distribution of the lesions throughout the mesenchymal system was much the same in both conditions. The author concludes that the lesions in the mesenchymal system seen in rheumatic fever can only be explained on the basis of alterations in its immunobiologic reaction; that therefore the basis of rheumatic fever is a hyperergic mechanism.

The concept is not new. The work does not represent anything very original or significant. It should, however, be of some interest to the pathologist and the internist.

**Practical Methods in Biochemistry.** By Frederick C. Koch, Director of Biochemical Research, Armour & Co., Chicago, and Martin E. Hanke, Associate Professor of Biochemistry, University of Chicago, Chicago. Fifth edition. Cloth. Price, $3. Pp. 419, with 22 illustrations. William Wood & Co., Mount Royal and Guilford Aves., Baltimore 2, 1948.

The present edition of this laboratory manual has kept abreast of new developments by including technics recently developed in biochemistry. The material in the book has been expanded by a greater elaboration of manometric methods, the inclusion of microbiologic procedures for vitamins and amino acids and the incorporation of new or revised colorimetric and fluorometric methods.

The manual is intended to present to medical students qualitative and quantitative methods of analysis used on cell constituents and body fluids. The experiments are classified into sections concerning The Chemistry of Cell Constituents, The Chemistry of the Digestive Tract, and Blood and Urine. The appendix includes instructions for preparing the reagents and solutions used. The experiments are clearly described in detail.

Undoubtedly, this is one of the better small books available for its intended purpose in this field.

**Subacute Bacterial Endocarditis.** By Emanuel Libman, M.D., and Charles K. Friedberg, M.D., Adjunct Physician, The Mount Sinai Hospital, New York. Edited by Henry A. Christian, A.M., M.D., LL.D. [Reprinted from Oxford Loose-Leaf Medicine with the same page numbers as in that work.] Second edition. Cloth. Price, $3.50. Pp. 346(1)-346(113), with 19 illustrations. Oxford University Press, 114 Fifth Ave., New York 11, 1948.

Dr. Friedberg has fully revised this valuable volume, the earlier result of a lifetime of study of bacterial endocarditis by the late Dr. Libman. The advent of a satisfactory therapy has necessitated emphasis on early diagnosis and treatment. The necessity for a bacterial diagnosis is emphasized by the fact that organisms not susceptible to penicillin may be treated with streptomycin or other more recent antibiotics. This is an excellent study of bacterial endocarditis and almost necessary for those not fully familiar with the subject who may occasionally treat this disease.

**Organic Chemistry with Applications to Pharmacy and Medicine.** By Eldin V. Lynn, Ph.D., Professor of Chemistry, Massachusetts College of Pharmacy, Boston. Third edition. Fabrikoid. Price, $5. Pp. 355. Lea and Febiger, 600 S. Washington Square, Philadelphia 6, 1948.

This book was written to serve as a textbook for the teaching of organic chemistry to students of pharmacy and medicine. In general, it is organized as are most textbooks of organic chemistry, treating the aliphatic hydrocarbons and their substitution products in the first chapters, followed by material on the aromatic hydrocarbons and their substitution products. Several chapters are devoted to the condensed nuclei and the various heterocyclic systems and a number of chapters deal with such special topics as alkaloids, proteins, enzymes, glycosides and resins.

Each of the chapters has a general introduction dealing with nomenclature and the general physical properties of the class involved, followed by sections on the preparation of the members of the class and the various group reactions. The unique feature of the textbook is that portion of each chapter which treats the chemistry of compounds found in the United States Pharmacopoeia, the National Formulary and New and Nonofficial Remedies.

The discussions of the subjects are rather brief and are almost outline in form; however, most of the fundamental reactions and general principles are presented. The third revision was written to include the more recent advances in drug therapy as found in the last editions of U.S.P., N.F. and N.N.R.

# Queries and Minor Notes

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

## DEFERMENT OF CHILDBEARING

*To the Editor:*—How long is it safe for a couple to put off having children? Some of my confrères say that after three years the chance of barrenness is much greater. M.D., Kentucky.

Answer.—How long it is safe for a couple to put off having children will depend in large measure on the age of the wife. If she is in the early twenties, postponement of conception for three years or so would be generally safe. On the other hand, if she is 35 or over, it would not be safe; and even if she were 30 it would be unwise. The reason for this lies in the aging factor. Thus, the incidence of sterility due to such conditions as fibromas, endometriosis and ovarian dysfunction is greater at 35 than at 25 and increases slightly year by year after the latter age. Unpublished data, moreover, indicate that even in the absence of demonstrable pathologic lesions, the average time for conception to take place after marriage (no contraception being used) is longer in women in the thirties than in those in the twenties. This important problem is currently the subject of wide study, but publications covering the specific question cannot be cited at present.

## SARCOIDOSIS

*To the Editor:*—A 23 year old Czech who had inflammation of the lungs during military service without being confined to bed has had sarcoidosis pulmonum for over a year. The patient's illness is not getting better and his strength is decreasing. Medical examination of the lungs shows a tumorous condition in the lower part on both sides of the lungs, considered to be sarcoidosis pulmonum. M.D., Czechoslovakia.

Answer.—The cause of sarcoidosis is not known. The histopathologic aspects of the condition closely resemble those of noncaseating tuberculosis. The disease can involve almost any organ. It seems, however, to have a predilection for lymph nodes, skin, the pulmonary parenchyma, the spleen and the liver. It may also cause inflammatory changes in the eyes and the salivary glands. At times it will cause characteristic changes in the small bones of the hands.

Some workers feel that sarcoidosis represents a form of tuberculosis; others have argued against tuberculosis as an etiologic factor. This has led to some confusion. If lesions of the skin or enlarged peripheral lymph nodes are found, it is advisable to obtain a specimen for biopsy. A preferred method of performing such a study is to save half of an excised lymph node for microscopic study and the other half for culture or injection into guinea pigs. Needle biopsy of the liver has also been suggested for microscopic diagnosis when other methods of examination fail.

A patient may have bilaterally large hilar lymph nodes. At times the term "potato" lymph nodes has been given to these mediastinal nodes because of their size. An infiltration may be seen throughout the parenchyma of the lung which may resemble that usually seen in tuberculosis, and yet it may be impossible to find tubercle bacilli in the sputum or the gastric contents. More frequently, the infiltration involves the basal or midlung fields, with symmetric distribution, and at times there is a universally distributed fine nodular or flocculent lesion visible in roentgenograms of the thorax. Results of the single strength and second strength tuberculin tests should be negative. Possibly the outstanding clinical feature is that the patient may have extensive changes in the pulmonary parenchyma or the hilar lymph nodes and still appear to be well and to have few symptoms.

In general, the prognosis in sarcoidosis is good, but evidences of the disease usually persist for a few years. Deaths rarely have been attributed to the condition. At this time there is no medicine that is of definite value in sarcoidosis. Vitamin D and chaulmoogra oil have been tried by various investigators. Roentgen therapy has yielded equivocal results. Streptomycin has shown little promise. The most important phase of treatment is directed toward an adequate amount of rest. The lesion in the thorax should be observed by means of serial roentgenograms of the thorax under the supervision of the patient's physician, and, if progress is unfavorable, additional efforts to detect tubercle bacilli should be undertaken.

## TREATMENT OF HICCOUGH

*To the Editor:*—A 72 year old white widower, with long-standing severe pulmonary emphysema, cor pulmonale of a moderate degree, secondary polycythemia and mild benign prostatic hypertrophy, has bilateral indirect inguinal hernia the size of lemons. In the past, his abdomen has been entered on three occasions for the removal of appendix and gallbladder and repair of the abdominal wall from the resultant injury. He has had gradually increasing dyspnea for several years and episodes of mild cardiac decompensation, controlled by rest, oxygen and digitalis. Depending on his water balance and other unknown factors, his urine has occasionally shown small amounts of albumin, and his blood, moderate nitrogen retention. Carbon dioxide–combining power stays at about 100 volumes per cent. The degree of his cyanosis is startling. He has had hiccoughs intermittently since September 1947. Periodic at first, they are now almost constant. When they are at a minimum, he does fairly well, getting out to an occasional motion picture and for an automobile ride. When they are severe, he can only lie in bed at home in an oxygen tent. For the hiccoughs the following therapeutic efforts have been made: (1) all the old home remedies; (2) meperidine hydrochloride; (3) methadone; (4) atropine; (5) barbiturates; (6) paraldehyde; (7) ether; (8) alcohol; (9) oxygen by all routes of administration except intravenous; (10) bleeding to a hematocrit reading of 42 per cent; (11) mercurophylline administered intravenously and intramuscularly; (12) various expectorants; (13) aminophylline by all routes; (14) myanesin® (3-ortho-toloxy-1, 2-propanediol); (15) succinic acid administered intravenously; (16) ephedrine; (17) epinephrine; (18) antihistaminics; (19) autogenous vaccine, and (20) penicillin aerosol. Since his breathing reserve is so low and since both leaves of the diaphragm are involved, it has been felt that phrenic nerve interruption would be too dangerous. Because of his large hernias and the multiple previous laparotomies, pneumoperitoneum has been felt to be contraindicated. An abdominal belt was not of benefit. This patient's hiccoughs are literally killing him. Do you have any suggestions as to what might stop them? Christopher Parnall Jr., M.D., Rochester. N, Y.

Answer.—The great deterrent to treatment in this case is the very high carbon dioxide–combining power. The time-honored treatment of hiccough is carbon dioxide inhalations and lastly operation on the phrenic nerve. It is assumed that carbon dioxide was not used in this case because of the exceedingly high carbon dioxide–combining power.

A carbon dioxide–combining power of 100 volumes per cent is hard to explain, even in this case. One must assume that it does not represent true alkalosis because of the lack of other symptoms, unless one accepts the hiccough as evidence of alkalosis. Theoretically, it might be assumed that there is a large residue of carbon dioxide in the dead spaces of this emphysematous lung and that the large quantity of sodium bicarbonate is present to offset this material. Therefore it would do no great harm to give carbon dioxide inhalations together with oxygen. The only danger would be respiratory acidosis. The maneuver would have to be carefully carried out and the effects carefully observed. Oxygen with 5 or 10 per cent carbon dioxide would seem preferable.

Operation on the phrenic nerve should be seriously considered. Certainly the respiratory function is greatly reduced by the diaphragmatic spasm and it is doubtful whether it would be much further reduced by paralysis of one side of the diaphragm. Obviously the phrenic nerve should be crushed on the side in which the spasm occurs. At any rate if the hiccough is in fact killing the patient almost any procedure that offers even a slight hope is justified.

Lastly, the cause of the hiccough should be considered. Reflexes from the gastrointestinal tract might be reduced by full atropinization. Psychic causes should be considered, although psychotherapy in a patient 72 years of age does not offer much encouragement.

## TUBERCULOSIS IN PREGNANCY

*To the Editor:*—I am interested in comparing the effects of tuberculosis in pregnant women with the effects of coccidioidomycosis in pregnant women. Does the eventual outcome of tuberculosis have any correlation with the trimester of pregnancy in which the disease is diagnosed? Is there a higher incidence of miliary tuberculosis and/or tuberculous meningitis depending on the trimester that the disease is diagnosed, or is the incidence of these complications the same regardless of pregnancy?

Hall Ramirez, M.D., Bakersfield, Calif.

Answer.—1. An accurate statistical answer is not available. In general, diagnosis in early pregnancy is desirable because it allows time for the institution of collapse therapy procedures. In late pregnancy it is often difficult to start such procedures and they are frequently deferred until delivery has taken place.

2. The entire question of the effect of pregnancy on tuberculosis is controversial, and widely divergent views have been expressed. It is generally held that patients do well during the period of pregnancy, but many show evidence of rapidly progressive disease during the postpartum months. The failure of these patients is held by some to be caused by a specific influence of pregnancy on tuberculosis; by some it is believed to be a mechanical effect due to the decompression of the chest at deliv-

**Krebsmetastasen.** Von Dr. med. Hans E. Walther, leitender Arzt der Röntgenabteilung des Schwesternhauses vom roten Kreuz in Zürich. Vorwort von Prof. Dr. H. von Meyenburg, Direktor des Pathologischen Institutes in Zürich. Cloth. Price, 60 Swiss francs; $18. Pp. 560, with 359 illustrations. Benno Schwabe & Co., Klosterberg 27, Basel 10; Imported by Grune & Stratton, Inc., 381 Fourth Ave., New York 16, 1948.

The physician's interest in patients with cancer frequently diminishes in proportion to the spread of cancer from its original site to other organs, because medicine or surgery offers little to relieve metastatic cancer and radiation therapy is at best only palliative. Neoplastic metastases, therefore, are seldom the subject of intensive scientific study.

This book, written in German by a Swiss radiologist, attempts to fill this gap in the medical literature and is based on many years of clinical experience and extensive study of pathologic-anatomic material. Postmortem examinations on 3,433 patients with cancer form the basis for the author's thoughtful monograph. An attempt is made to uncover guiding principles which govern the spread of cancer and thus to facilitate the evaluation of the prognosis in different types of malignant growths.

The book is divided into two main parts. In the general section, the morphologic and biologic qualities of the cancer cells and the grading of malignancies are explained and the author's "malignancy index" described. The latter is determined by adding the continuous extension ($c$) of the tumor, its lymphatic spread ($l$) and its hematogenous ($h$) spread, all of which are arbitrarily evaluated in a relation of 1:2:10 and divided by 100. Therefore, the formula of the "malignancy index" is as follows:

$$M = \frac{c + 2l + 10h}{100}$$

According to the author, the occurrence of metastases follows closely the anatomic design of the blood vascular system and can be predicted if the primary site is known. Conversely, if neoplastic metastases are found in various organs, the site of the primary lesion can usually be assumed with a high degree of certainty. The author is convinced that all metastases to lymph nodes are "regional." They are either "primary," if they are localized in the draining area of the primary tumor, or "secondary," if the tributary organ is invaded by way of the blood system. The author does not accept the theory of lymphatic connections between two different organs. The possibility of "retrograde" lymphatic spread is refuted by the author, and so this controversy is continued. The chapter on diagnostic methods of neoplastic metastases is short, and cytologic methods are discussed. The Papanicolaou stain, chiefly important for the diagnosis of primary lesions, is not mentioned.

In the special section, the frequency of different types of malignant growths in the various organs is described, and growth tendencies and modes of spread analyzed. Statistical evaluations support the author's theories.

The book is well written and offers a wealth of material for thought. It is a fascinating piece of work by an earnest and experienced clinician who expresses his ideas in a convincing manner. Minor differences of opinion as to the frequency of metastases in different organs do not depreciate the value of a readable and highly recommendable work.

At any rate if the hiccough is in fact killing the patient almost any procedure that offers even a slight hope is justified.

Lastly, the cause of the hiccough should be considered. Reflexes from the gastrointestinal tract might be reduced by full atropinization. Psychic causes should be considered, although psychotherapy in a patient 72 years of age does not offer much encouragement.

## TUBERCULOSIS IN PREGNANCY

**To the Editor:**—I am interested in comparing the effects of tuberculosis in pregnant women with the effects of coccidioidomycosis in pregnant women. Does the eventual outcome of tuberculosis have any correlation with the trimester of pregnancy in which the disease is diagnosed? Is there a higher incidence of miliary tuberculosis and/or tuberculous meningitis depending on the trimester that the disease is diagnosed, or is the incidence of these complications the same regardless of pregnancy?
Hall Ramirez, M.D., Bakersfield, Calif.

ANSWER.—1. An accurate statistical answer is not available. In general, diagnosis in early pregnancy is desirable because it allows time for the institution of collapse therapy procedures. In late pregnancy it is often difficult to start such procedures and they are frequently deferred until delivery has taken place.

2. The entire question of the effect of pregnancy on tuberculosis is controversial, and widely divergent views have been expressed. It is generally held that patients do well during the period of pregnancy, but many show evidence of rapidly progressive disease during the postpartum months. The failure of these patients is held by some to be caused by a specific influence of pregnancy on tuberculosis; by some it is believed to be a mechanical effect due to the decompression of the chest at deliv-

cry, and a minority of observers deny that the course of the tuberculosis is influenced in any way by the pregnancy. Many studies of this problem have been attempted; the majority of clinicians conclude that pregnancy has a deleterious effect on tuberculosis; a few have the opposite opinion. Meningitis and miliary tuberculosis seem to occur more frequently among pregnant women, but no information is available indicating a greater tendency to occur in any particular trimester.

In contrast to the difficulty in analyzing resistance in tuberculosis, allergy can be measured easily. Quantitative tests (Lichtenstein, M. R.: Tuberculin Reaction in Tuberculosis During Pregnancy, *Am. Rev. Tuberc.* **46**:88, 1942) have demonstrated that allergy diminishes during the third trimester among tuberculous patients and returns to its former level soon after delivery.

## MYELOID DEPRESSION FROM COPPER

*To the Editor:*—Information is requested concerning myeloid depression following exposure to "corona 50 per cent plus" copper carbonate. A 57 year old farmer in excellent health used this product, mixing it with the wheat in a truck bed. In addition wind blew dust from the drill to the driver. The patient experienced a headache, hacking cough and a metallic taste in mouth, and later increasing weakness, substernal oppression on exertion and generalized purpura. Physical examination revealed no abnormality except for marked pallor. The red blood cell count was 1,940,000, the hemoglobin 6.4 Gm. per hundred cubic centimeters, white blood cell count 3,650, coagulation time 4 minutes, bleeding time 20 minutes; sedimentation rate 16 and clot retraction time 2½ hours. Since admission four days ago, with daily transfusions, the red blood cell count has risen to about 3,500,000 with the white blood cells remaining below 3,000. Sternal puncture revealed only mature red blood cells with occasional lymphocytes. The purpura has cleared up, bleeding time has returned to normal and a septic fever has developed. Is copper carbonate a known cause of primary refractory anemia?

E. T. Cook, M.D., Anadarko, Okla.

[This inquiry was referred to two authorities, whose respective replies follow.—Editor.]

Answer.—Copper carbonate has never been reported as a cause of primary refractive anemia in man, nor is there any evidence from experimental work that copper in any form produces anemia. The only important evidence of disease in human beings resulting from exposure to copper salts is the allegation that it may be responsible for certain cases of hemochromatosis. This claim has never been generally accepted.

Answer.—Such heavy metals as arsenic, gold, bismuth and mercury are known to produce a refractory anemia. Reports could not be found of such an anemia following the administration of copper. Toxic doses of copper produce hemolytic anemia in animals (*Am. J. Path.* **7**:351, 1931). Brodsky (*Arch. f. Gewerbepath. u. Gewerbehyg.* **5**:91, 1933) observed a variety of toxic symptoms in workers inhaling copper carbonate dust during the mixing with grain. The symptoms included fever, disagreeable taste in the mouth, nose bleeds, headache, cough, dyspnea and vomiting. No mention is made of changes in the blood picture. These persons recovered from the intoxication within a few days.

## EXPANDED TONSILLECTOMY

*To the Editor:*—What is present opinion concerning the desirability of an "expanded" tonsillectomy (Myersberg) as compared with the "usual type" in an average child in whom tonsillectomy is indicated? What are the advantages and dangers of each? What is the approximate frequency of use of each?

M.D., New York.

Answer.—A well conducted tonsillectomy of the "usual type," which includes the separate removal of the tissue of a well developed plica triangularis and any fairly well developed lymphoid structures lying between the tonsil and the lateral aspects of the base of the tongue, will accomplish all that may reasonably be expected of this operation.

From written descriptions of the so-called expanded operation, there is no reason to believe that it is not equally effective if one wishes to learn the technic and acquire the armamentarium.

The advantages or dangers of one over the other do not appear sufficient to warrant a prejudiced attitude for carrying out one technic to the exclusion of the other.

It is practically impossible to state in accurate figures how many of the "expanded" tonsillectomies are being done. However, the number of the "usual type" must be vastly greater. The "expanded" type of operation in large parts of the country is practically unknown.

Examination of a number of relevant textbooks, all published in recent years, fails except in one instance to show a discussion of this "expanded" method. The exception is the work edited by Jackson and Coates, published in 1929.

## SIALORRHEA

*To the Editor:*—What is the effective treatment for persistent sialorrhea? The patient is 70 years old and has arteriosclerotic heart disease for which he receives digitalis daily. He has had bronchial asthma for thirty years and has had sialorrhea for the past five years. Sputum varies in consistency from watery to thick mucous.

M.D., New York.

Answer.—Treatment of sialorrhea is aimed at the cause, and success depends on whether the cause can be found and a response is possible. There are many causes for salivation. Drugs, stomatitis, dental difficulties, vitamin B deficiencies, reflexes from the intestinal tract and other organs, psychic causes and organic disease of the central nervous system are among the most common ones. The patient's age and sex, the duration and persistence of the condition and the absence of notable digestive disorders would exclude a number of possibilities.

It is possible that the best diagnostic chance, based on the history, is that the chronic parasympatheticotonic (asthmatic) condition, in an arteriosclerotic man who could have a basal gangliar degeneration, has resulted in the sialosis. Stomatitis, smoking and avitaminosis could be contributing factors.

Atropine is the only drug of use, but its value may be limited by side effects. One could try it cautiously, giving 1/240 grain (about 0.25 mg.) after breakfast and lunch, doubling the dose if indicated, but being alert for toxicity. It probably would not be contraindicated by the cardiac condition and might help the asthma. The mouth should be cleaned up, and a vitamine B complex concentrate empirically given for several weeks. Irradiation of the salivary glands is known to decrease the flow, but often produces a dry mouth.

## EXPOSURE TO OILS

*To the Editor:*—For a considerable part of their working day, attendants at auto service stations and even more so men who clean out oil tankers inhale finely atomized petroleum oils. In view of the general warning against oily nose and throat sprays, are these men more afflicted with pulmonary disease such as tuberculosis, cancer and interstitial pneumonia than the general average? They never use respirators.

Bernhard A. Fedde, M.D., Brooklyn.

Answer.—In addition to the occupations mentioned, many others involve continuous exposure to oils. In a limited number the sole employment centers about the spraying of metal parts with oils. At times the local atmosphere is laden with oily mists. Nevertheless, with the exception of dermatitis, the incidence of occupational diseases is low. In the case of dermatitis the offending agent is more likely to be some additive such as sulfur or chlorine. The well known "oil furunculosis" usually derives from no precise irritant but from inadequate skin cleanliness. Even in the absence of suitable inquiry it may be recognized that while the total number of scrotal and penile cancers may be low, the incidence is higher among the oil using trades of the United States. Pulmonary cancers from oils are so rare that a single case attracts attention. In other countries and notably the British Isles, cancer from oils is of more frequent occurrence. The "spinning jenny" cancers of the textile trades in the British Isles constitute a common occupational disease. This difference is attributed to the source of the oils. The Scottish shale oils are high in cancerigenic agents, as are some Balkan and Asiatic crudes. In the United States, the several oil fields differ as to base nature, but none is rich in cancerigens, although not wholly lacking in some. In part, the apparent rarity of pulmonary cancer among oil workers may be due to lack of suitable investigation. In any circumstance, increased numbers may shortly be expected, since it is only a question of time until shale oils and fuels will be produced in this country together with increased dependence on oil imports with their higher cancerigenic content. All such items are ably presented by Hueper in his "Occupational Tumors" (Springfield, Ill., Charles C Thomas, Publisher, 1942).

## ANEMIA IN X-RAY DEPARTMENT PERSONNEL

*To the Editor:*—I look after the health of a hospital staff. Some persons working in the x-ray department have anemia, normocytic and normochromic in type. What preventive measures should be taken, and what treatment do you suggest?

M.D., Canada.

Answer.—This is evidently a group of persons who have anemia, but whose red blood cells are normal in size and the color index is 1. If the normocytic, normochromic anemia was the result of exposure to roentgen rays it would be an advanced symptom (tendency to hypoplastic or aplastic anemia or "refractory anemia") and would be associated with a decrease in the number of white blood cells and platelets. If these are not decreased in number, it may be associated with nephropathy or there may be a hemolytic factor. Normocytic anemias are sometimes noted in certain endocrine deficiencies, but it is not probable that a group of persons would be affected at the same time. Chronic infections are more frequently associated with a hemoglobin deficiency type of anemia (hypochromic). If a vacation of four weeks, away from the x-ray department, is not followed by improvement, the susceptible persons ought to avoid the possibility of damage to the blood-forming organs by further exposure to roentgen rays. Presumably there is no iron or liver extract deficiency, so that theoretically there would be no indication for these medicines. If a dilution factor could be demonstrated in the blood, a higher intake of protein could be tried.

## MYELOGENOUS LEUKEMIA

*To the Editor:*—A Puerto Rican male, 43 years old, complained of abdominal discomfort. His history was noncontributory and tropical diseases were denied. Examination showed the spleen extending almost to the navel. Other clinical findings were normal. The blood cell count revealed 12.5 Gm. hemoglobin per hundred cubic centimeters, 4,940,000 erythrocytes and 2,800 leukocytes, with 54 per cent segmented cells, 38 per cent lymphocytes, 4 per cent band cells, 1 per cent metamyelocytes and 3 per cent eosinophils; there was moderate anisocytosis and poikilocytosis. Malarial parasites were not seen on smear. The urine was amber, cloudy and acid in reaction; there was insufficient quantity to observe specific gravity; tests for sugar and albumin were negative in result; many mucus threads and occasional epithelium were observed on microscopic examination. The Wassermann reaction was negative. A sternal puncture was performed, and the pathologist reported that the finding was compatible with myelogenous leukemia. Diagnosis was subleukemic leukemia. The general condition of the patient was not bad; he is weak, has lost weight and is unable to do manual work. Is splenectomy indicated, or should I continue with arsenic and vitamins? Is a different treatment indicated?

Stephen F. Saxl, M.D., New York.

Answer.—The answer to this question depends, in part, on the accuracy of the pathologist's conclusion that the findings were compatible with those of myelogenous leukemia. That, certainly, is a plausible diagnosis as judged by the limited information given. If this is the correct diagnosis, splenectomy is not indicated. Such an operation is not likely to do good and carries a substantial risk operatively and postoperatively.

Assuming that the diagnosis is myelogenous leukemia in a subleukemic stage, urethane, roentgen irradiation or even nitrogen mustard may be considered as well as arsenic, in selecting a therapeutic agent. However, if the patient does not have complaints at this time, nothing need be done. If the abdominal tumor becomes troublesome of itself, local irradiation may be helpful. Vitamins are not indicated. In fact, there is some evidence that folic acid may actually aggravate leukemia.

## DIETHYLSTILBESTROL IN ENDOMETRIOSIS

*To the Editor:*—What is the dose of diethylstilbestrol that will suppress menstruation in a case of suspected endometriosis? Is such a trial advisable?

M.D., Massachusetts.

Answer.—The dose of diethylstilbestrol which will suppress menstruation (with or without endometriosis) varies with the patient. The bigger the dose the better and the quicker it suppresses the period, but, unfortunately, in many women nausea and vomiting prevent the larger dosage. Giving diethylstilbestrol just as the patient goes to bed prevents some of the nausea. One can start with a 5 mg. dose and increase it each night by one tablet (5 mg.) until 25 mg. a day is being taken, stopping when nausea becomes severe, or one can start with 25 mg. each night, reducing it 5 mg. each night if nausea supervenes. The latter method seems to work faster.

The second question can only be answered by saying that we do not know whether it will suppress endometriosis or whether it is advisable. We do know that the small doses produced by the normally menstruating ovary make endometriosis worse or cause it to progress. Whether the stimulating effect of large doses of estrogen on the endometrial-like tissue is greater than the ovulation-suppressing effect of the large doses is not at present fully known.

## ETIOLOGY OF URINARY CALCULI

*To the Editor:*—A 30 year old white man was stationed with the Air Force in Accra, British West Africa, during the war. Since returning home he has had four severe attacks of renal colic. Each time a stone was passed, an analysis of one of the stones showed it to be a calcium compound. He has been on a low calcium diet, which was recommended by a urologist, but has continued to form stones. The patient tells me that renal stone formation amongst the native population of Accra is common, many dying from complications. The patient's past history and his family history are noncontributory. Is it possible that ingestion of the water of Accra (the source of trouble in the natives) has influenced the chemical process of the body so that he will continue to form stones? Have similar cases been reported?

M.D., Massachusetts

Answer.—The etiology of urinary calculi is complex and includes factors of infection, stasis or obstruction, deficiency diets, excessive excretion of calcium due to various causes for mobilization of calcium from the bones or, more rarely, to excessive oral intake. In addition there are probably constitutional predisposing factors in some instances. The high incidence of renal stone formation among natives in India, Africa and other poverty stricken areas is undoubtedly related to severe dietary deficiency. In hot climates where the water supply is poor, stones may develop within weeks or months if the subject neglects to maintain a sufficiently large fluid intake. This was demonstrated in Army experiences during the recent war. If, in such circumstances, immobilization occurs as a result of illness, or if the ration contains considerable calcium, precipitation in the urinary tract can easily occur. The ingestion of the local water would be an aggravating factor only if it happened to contain a large amount of calcium. This influence would cease, however, with departure from the particular region.

The continued formation of urinary calculi in a patient must therefore be ascribed to one or more of the other factors listed. It is assumed that a careful study of the urinary tract has been made to exclude stasis and infection. Dietary treatment is not successful although, if the stone consists of calcium oxalate, foods containing large amounts of oxalate such as chocolate, beets, spinach, rhubarb and Swiss chard should be eliminated from the diet. Intake of milk and cheese should also be restricted. The most important item, however, is the large fluid intake, enough to produce at least 3 liters of urine daily. Hyperparathyroidism should be excluded by appropriate tests.

Pierce, L. W., and Bloom, B.: J. Urol. **54**: 466, 1945.

## GALACTORRHEA

*To the Editor:*—A 30 year old white married woman has 1 child, aged 2½. In November 1948 the patient noticed the sudden onset of bilateral lactation without apparent cause. She feels fine otherwise. She is not pregnant and her menstrual periods are completely normal. Pelvic examination was negative. Examination of the breasts by palpation and transillumination did not reveal abnormality. There has been little or no manipulatory stimulation of the breasts. The patient is completely feminine in appearance without outward signs of glandular dysfunction. In October 1948, one month prior to the onset of the lactation, the patient had an attack of herpes zoster involving the five lower intercostal spaces and ribs as well as the back on the right side. The skin lesions have disappeared, although some burning and pruritus remain over the involved area. Since the abnormal lactation began, she has received the following medication without apparent effect: (1) testosterone, 5 mg. daily for seven weeks; (2) diethylstilbesrol, 10 mg. daily for four weeks; (3) diethylstilbestrol and testosterone, 5 mg. daily of each for four weeks. These medicaments were administered for approximately twenty-three days of each menstrual cycle and were omitted during the period itself. Despite the treatment, lactation has continued without interruption and recently has been increasing in quantity. The breasts are painful and the apparently normal milk is expressed with the slightest pressure. There have not been other signs of abnormal secretion. 1. What are the causes for this condition? 2. Are any further laboratory measures indicated? 3. What therapeutic measures might terminate the secretion? 4. Is there any known relationship between shingles and "idiopathic lactation"?

David L. Cronin, M.D., Reseda, Calif.

Answer.—1. This condition called galactorrhea may be due to a variety of conditions including atrophy of the uterus and ovaries, neoplasms of the pituitary gland or midbrain structures, rare diseases of the brain and shock to the nervous system. The mechanism involved in galactorrhea is not understood. 2. There are no specific laboratory tests to be performed, but every effort must be made to be sure there is no pituitary or other brain disturbance, neoplastic or otherwise. 3. Treatment is unsatisfactory. However, it is recommended that 10 mg. diethylstilbestrol be continued daily for at least three months, and if necessary even up to six months. Roentgen therapy applied directly to the breasts may suppress the secretion of milk but is not advisable in a woman only 30 years of age.

Likewise, radiation treatment to the pituitary gland may stop the flow of milk, but this treatment also may not be harmless; hence, more time should be permitted to elapse to see what further estrogen treatment will do. 4. There is no apparent connection between herpes zoster and galactorrhea.

## PULMONARY EMBOLISM IN HEMIPLEGIA

*To the Editor:*—A 19 year old sailor was observed to have subacute bacterial or acute bacterial endocarditis, embolic phenomena, fever, enlarged spleen and roughened mitral murmur in systole. Six cultures were negative and therapy was withheld for three days. Treatment with progressively increasing doses of penicillin was instituted, up to 10,000,000 units daily, before fever was controlled in the face of increasing symptoms. On the eighth day of therapy, which consisted of intravenous drip during the day and intramuscular drip during the night, gradually occurring hemiplegia of the right forearm and hand developed, and he remained in near coma for five days. He regained full mental capacity and clear speech after two weeks. Passive movements and massage on the paralyzed leg were begun within three days after the cerebral accident. Repeated circulation times were normal. What appeared to be three pulmonary emboli developed. The first was not recognized, but the two later ones two days afterward at about two hour intervals were characterized by dyspnea, substernal pain, a sense of impending disaster and confusion and perspiration. Penicillin was increased to 20,000,000 units by continuous intravenous route, and administration of heparin was begun immediately, with an eventual change to dicumarol.® The patient is alive and afebrile after three months. 1. How frequent are pulmonary emboli in cases of hemiplegia in young subjects with previously normal veins? 2. Is venous insufficiency any more frequent when ligation is performed in the presence of paralysis and sensory loss in the leg? 3. In view of the frequent reports of cerebral hemorrhage occurring in patients treated with anticoagulants was a venous ligation to be preferred after the initial attack had subsided?

F. E. Wetzel, M.D., San Francisco.

Answer.—Pulmonary embolism has occurred rarely in patients who have had hemiplegia irrespective of their age. The venous system probably would not become insufficient after ligation in the presence of paralysis and sensory loss in the leg. The collateral circulation is so good in young persons that the effect of it on the normal venous circulation would hardly be detectable, providing the interruption was distal to the profunda femoris vein or to the saphenofemoral junction. In any patient who has had a pulmonary embolism that is nonlethal, the best method of treatment, providing a competent vascular surgeon is available, is to interrupt the femoral veins in both groins. These interruptions should be just distal to the saphenous vein; if a thrombus is found in the femoral vein, a thrombectomy may be done at the same time. In summary, the safest method of treatment in competent hands for your patient probably would have been interruption of both femoral veins. Further experience with the anticoagulants is still necessary to determine whether this method of therapy is as satisfactory as interruption of the femoral vein in the presence of recognizable venous thrombosis and pulmonary embolism.

## EXPOSURE TO CHLORINE AND HEART DISEASE

*To the Editor:*—A 41 year old white man has complained of shortness of breath and nonproductive cough for one year. He states that he was in good health until exposed to an unusually heavy concentration of chlorine gas while at work. Immediately after this exposure he was hospitalized four days with acute respiratory symptoms. He has had profuse night sweats for several months and reports a weight loss of 24 pounds (10.9 Kg.) in one year. He has previously been digitalized and has received weekly injections of a mercurial diuretic. On examination, the man appeared acutely ill with moist rales scattered through both lung bases. The heart was grossly enlarged with a definite apical thrust both visible and palpable in the midaxillary line. Significant murmurs or thrills were absent. The blood pressure was 166 systolic and 116 diastolic. Strong femoral pulsations were felt bilaterally. The liver was not enlarged and there was no dependent edema in the ankles. Films and fluoroscopy of the chest showed a typical water bottle shape, increased in all diameters. Evidence of pulmonary tuberculosis was lacking. Blood count showed moderate hypochromic anemia with a total white cell count of 12,700 with 85 per cent polymorphonuclear cells and 15 per cent lymphocytes. Urinalysis revealed a trace of albumin and a few hyalin and finely granular casts. The sputum contained blood, but smears and cultures were negative for tubercle bacilli. A blood culture was negative. While the roentgen observations are suggestive of pericardial effusion, the blood pressure and loudness of the heart sounds on auscultation and the prominence of the apex beat tend to support the probability of a severe hypertensive cardiac disease with cardiac dilatation. Are any reports available indicating that cardiac dilatation and chronic failure may result either in a normal or previously damaged heart from exposure to chlorine?

Donald N. Fowell, M.D., Stockton, Calif.

Answer.—The problem of a possible relationship of exposure to chlorine gas with respiratory symptoms and cardiac failure is difficult to evaluate in this case. The presence of hypertension and enlargement of the heart to the left and right suggest that cardiac failure might be on the basis of hypertension alone. However, the development of cor pulmonale secondary to pulmonary fibrosis resulting from chlorine inhalation cannot be excluded with the data presented. The electrocardiogram and pulmonary physiologic studies, if compensation could be effected, would be helpful. A survey of recent literature fails to reveal documented cases of heart failure secondary to the inhalation of noxious gases. Acute pulmonary edema is not unusual and responds to positive pressure administration of oxygen. However, Winternitz and his co-workers have produced pulmonary fibrosis in experimental animals following inhalation of irritating substances.

## TREATMENT OF TRIGEMINAL NEURALGIA

*To the Editor:*—During the past year I have treated successfully 3 cases of trigeminal neuralgia with repeated injections of vitamin B complex. Since all the books still consider it a purely surgical problem I would greatly appreciate your comment.

Edmund Fremont, M.D., Manito, Ill.

Answer.—This is an old story. Trigeminal neuralgia can be temporarily successfully treated with any form of therapy as it is a characteristic of the disease that it subsides spontaneously. When it is the first attack of the disease which is so treated the results are apt to be particularly gratifying, as the freedom from further difficulty, after the first attack has subsided, often persists for two or three years regardless of the type of treatment. However, when the pain returns the treatment which originally proved so successful, whether it be vitamin B complex or some other type of medical therapy, practically never succeeds again. Only injection of the nerve with alcohol, section of one of the peripheral divisions or of the sensory root back of the gasserian ganglion can be relied on to relieve the pain of this disease with certainty, but only section of the root back of the ganglion will give permanent relief. The use of vitamin B in the treatment of trigeminal neuralgia has often been recommended, and there are numerous publications dealing with this form of treatment. It is unfortunate that it is not effective.

## HIGH INTENSITY SOUND WAVES IN AVIATION

*To the Editor:*—Pilots have inquired of me of the possible effect of "high frequency" and "high intensity" sounds and vibrations on the production of fatigue. I quote from a pilot's letter: "It is felt that the sounds and vibrations we are worrying about are those not heard by the human ear, and possibly the vibrations are so high in frequency that they are not felt by the human body. For example, there is a dog call whistle which cannot be heard by human beings, but will attract the attention of a dog at a considerable distance. We believe that such sounds and vibrations come from propellors or slipstream hitting along various windshield corners or other irregularities on the fuselage or other parts of high speed aircraft." I am unable to find any information on "sounds unheard" and "vibrations not felt" by the human body.

Herbert F. Fenwick, M.D., Chicago.

Answer.—Clinical or experimental evidence to indicate that sound waves above the frequency range audible to the human ear can produce auditory fatigue or acoustic trauma has not been reported. Extremely high intensities of these so-called supersonic sound waves at close range can cause tissue destruction by the production of heat. However, the intensity of sound generated around the moving parts of an airplane would be much below this intensity level.

It is a safe rule that "what the ear cannot hear will not harm it."

## TOXICITY OF PIPE-SEALING COMPOUNDS

*To the Editor:*—Does Leadite,® manufactured in Philadelphia, contain toxic material that would produce anemia and nephritis?

Fred Pulgram, M.D., Trenton, Ill.

Answer.—This product, manufactured by the Leadite Company, Inc., Girard Trust Company Building, Philadelphia, is believed to represent a pipe joint sealer. Since there are scores of compounds of this nature, the reply made is general rather than specific. Ordinarily, these substances fall into two groups; those that contain lead and those that do not. Frequently, the non-lead-bearing agents are promoted as containing no poisonous substances and represent various mixtures of Portland cement, flour, tar, talc and lampblack. The leaded types are usually made in paste form and involve mixtures of divers lead compounds in oils and glycerin. Theoretically, any and all of these compounds are applied only on the exterior of joint surfaces for sealing purposes, but some is likely to come in contact with the interior of pipes at the joint areas. This exposure might be the source of lead poisoning, particularly in large new housing projects where all piping is new. Actual tests as carried out by the Detroit Department of Health reveal no significant lead content in water. Such lead as appears shows up as "slugs" of such size as likely to attract attention and is discarded. The remote possibility remains that lead poisoning may arise from this source from the intake of a few small "slugs" of this leaded paste. The manufacture of these preparations, starting with dusty lead compounds, may constitute an industrial exposure. Considerable lead intake from any of these pipe joint compounds would cause lead poisoning. Anemia and nephritis might then arise, along with other indications of plumbism.

## TREATMENT FOR ENLARGED THYMUS

*To the Editor:*—A 10 month old male infant is in excellent condition except for an enlarged thymus gland. The first roentgenogram showed a borderline case of enlargement; two others, and roentgenograms taken since that time, also show it to be enlarged. He has had five roentgen treatments and now the roentgenologist suggests high voltage roentgen therapy or surgical removal. What do you consider the best treatment for this patient? Are there dangers in roentgen therapy? M.D., Pennsylvania.

ANSWER.—A 10 month old male infant in excellent physical condition might be expected to have a relatively large thymus gland. The only evidence of its enlargement, according to the query, was in two roentgen examinations. Most authors question the validity of an anterior-posterior roentgen measurement as being diagnostic of an enlarged thymus gland. Other causes for a widened supracardiac shadow in the roentgenograms are tracheobronchial lymphadenitis, mediastinal pleurisy, paravertebral abscess, mediastinal neoplasms, pulmonary atelectasis and consolidation.

Other authors disregard the transverse shadow and have attempted to demonstrate by lateral technic a thickened thymus gland which might encroach on the trachea. In a series of careful studies by this method over 50 per cent of normal infants seem to show a narrowing of the tracheal lumen.

As the thymus gland is composed of lymphatic tissue, rather sensitive to roentgen irradiation, it would seem that the five roentgen treatments should be more than adequate, particularly in view of the fact that the infant is entirely asymptomatic, and the only criteria for enlarged thymus in his case are the roentgen examinations. High voltage roentgen therapy might be dangerous, as there are other organs more vital to life in the region of the anterior mediastinum than the thymus gland. As a general rule, it may be stated that heavy roentgen dose is contraindicated and it would be much better to undertreat than overtreat with roentgen therapy.

There is absolutely no indication for surgical removal in a physically normal child who has shown no symptoms.

## DINITROPHENOL AND FORMATION OF CATARACTS

*To the Editor:*—I am much interested in the actions of dinitrophenol and its relation to the formation of cataracts. Has anyone been able to say definitely what toxic condition has been responsible for producing cataracts and what degenerative changes may occur as a result, not only in the lens of the eye but in the body? J. O. Chiapello, M.D., Chico, Calif.

ANSWER.—Dinitrophenol increases cellular metabolism primarily at the expense of fats and carbohydrates. A large number of clinical and experimental studies have not indicated the cause of the cataract formation. Horner (Dinitrophenol and Its Relation to Formation of Cataract, *Arch. Ophth.* **27**:1097, 1942) found only 0.86 per cent of all persons who ingested dinitrophenol afflicted with cataract. No correlation to the amount of drug taken, or to the length of time during which it was taken, or to the age of the patient could be established. Females may be more susceptible than males, and there is apparently a genetic susceptibility to cataract formation due to the drug. The usual laboratory animals are immune, but in baby chicks and baby ducks acute reversible lens opacities develop within a few hours after administration. The only characteristic lesions caused by the compound are bilateral progressive cataracts. Dermatitis, agranulocytosis, peripheral neuritis and hepatic, renal and cardiac damage have been described.

Buschke (Acute Reversible Cataract in Chickens Due to Various Nitro Compounds, *Am. J. Ophth.* **30**:1356, 1947) found a close correlation between cataract-producing properties of nitro compounds and ability to raise the basal metabolism of the animal. He postulated that a disturbance of the phosphorylative mechanism of the lens might cause dissipation of energy necessary to specific tissue functions and might result in cataract formation.

## SWEET TASTE SENSATION

*To the Editor:*—A middle-aged man is complaining of a strong, sweet taste in the mouth which at times becomes unbearable. He has had it constantly for three months. History and physical examination are negative. Please advise. H. J. Konstam, M.D., New York.

ANSWER.—The complaint of a constant, strong, sweet taste by a middle-aged man who does not show abnormal conditions may be due to the actual presence of a sweet-tasting material, to a neurogenic cause or to a psychoneurotic aberration. A sweet taste may arise from infection in the respiratory tract or mouth, or from a denture or wash, but it is unlikely that it would be as intense as described, and the taste from such causes is more commonly sour, bitter or foul. It is also improbable that it could be caused by a nerve lesion, and a central lesion in the temperosphenoid lobe usually produces fleeting hallucinations.

If a local cause can be excluded by a reexamination, the patient should be examined by a neuropsychiatrist. Hysteria, although usually showing multiple symptoms and obviously based on a suggestive background, can produce a constant, intense taste perversion—a conversion symptom based on a suppressed wish. A history of some change or stress or illness at the time of onset might be significant.

## EFFECT OF ROENTGEN TREATMENT ON BRAIN TISSUE

*To the Editor:*—Is anything known about the effect of intensive roentgen treatment on normal brain tissue? M.D., Pennsylvania.

ANSWER.—Nervous tissue, both of the central nervous system and the peripheral nerves, is notoriously resistant to the effects of irradiation. However, in those instances in which enormous doses of radiation have been given or in which moderate treatment has been repeated at intervals so that there is a large cumulative total dose, fibrosis (gliosis) has been noted and subsequent gross atrophy and shrinkage of the irradiated brain observed. With the ordinary large dose treatments not repeated too often, one can say that normal brain tissue is unaffected.

## ELECTROGALVANIC CURRENTS FROM DENTAL FILLINGS

*To the Editor:*—How can one determine and rule out burning sensation of the tongue due to electrogalvanic currents in the mouth as a result of metal fillings? William L. Dobes, M.D., Atlanta, Ga.

ANSWER.—One can determine the importance of electrogalvanic currents from fillings of different potential by indirect and direct means. 1. Be sure that another cause for the glossopyrosis is not present, such as glossitis, a deficiency (notably B complex), the use of an irritant (tobacco, a mouth wash, food or drink), an estrogenic deficiency, a deficiency of saliva, cancerophobia, a neurogenic or psychogenic source. 2. Burning from an electrical source is not common, and it occurs soon after dental repair. The sequence is usually obvious. 3. Removal of the guilty filling or denture and replacement by a temporary nonmetal filling is a direct therapeutic test which should be done only if indicated by the findings of numbers 1 and 2.

Some oral specialists feel that all forms of glossitis should be given therapy with a vitamin B complex concentrate. This is probably legitimate only when another specific cause cannot be found.

## TUBERCULIN REACTION AND ANTIHISTAMINICS

*To the Editor:*—What is the effect of antihistaminic drugs on the tuberculin skin reaction? Is it possible for a person with a positive reaction to tuberculin to obtain a negative skin reaction to tuberculin or to purified protein derivative of tuberculin by taking antihistaminic drugs prior to and during tuberculin skin testing? References, if any, will be appreciated. M.D., New York.

ANSWER.—There is a difference in opinion on this subject. However, trustworthy reports indicate that antihistaminic drugs do not modify the intradermal reaction or other manifestations of tuberculin allergy. The Koch phenomenon and tuberculin shock in tuberculous guinea pigs apparently persist in spite of previous injection of histamine. Articles on this subject which may be consulted are: Boquet, A.: *Annales de l'Institut Pasteur,* **69**:55, 1943, and Kreis, B.: *ibid.* **72**:308, 1946. Unpublished experiments in which tuberculous guinea pigs were given large injections of antihistamine and then tested with tuberculin indicate that significant modification of the tuberculin skin reaction did not result from the antihistamine injection.

## GALACTOSE TOLERANCE

*To the Editor:—Is galactose used in sugar tolerance tests? Is it in any way superior to the use of dextrose?*

Frederick Falkson, M.D., Walden, N. Y.

ANSWER.—The usual "sugar tolerance test" employs dextrose. It has clinical value in diabetes mellitus, renal glycosuria and in certain other conditions. Perhaps what is meant is the galactose tolerance test, or Bauer's test, which indicates the carbohydrate tolerance of the liver. This latter test is not very reliable, but if carried out properly it may be of value in the differential diagnosis of hepatic dysfunction. Galactose, like dextrose, is a simple sugar which is available in pure form. It is assimilated and converted into glycogen by the liver. It differs from dextrose, however, in that the rest of the body seems unable to store galactose and it is not a "renal threshold substance." Any good textbook on laboratory methods in clinical diagnosis discusses both of these tests.

## DEATH IN TERTIAN MALARIA

*To the Editor:—A 25 year old white veteran had severe chills, high grade fever and malaise of two days' duration. A blood film showed ring forms of the tertian malarial parasite. Quinacrine hydrochloride was prescribed in 0.1 Gm. doses; after he had taken four tablets he became disoriented and shortly after lapsed into a deep coma and became incontinent of stool and urine. The patient was hospitalized and died two hours after arrival. Just prior to death the temperature was 104 F. (rectally), and a diffuse macular rash and a few petechial areas appeared on the abdomen. Necropsy was not performed. Could this have been a case of cerebral malaria? The blood film showed tertian parasites only. Was this a case of adrenal disease of the Waterhouse-Friderichsen type?*

N. W. Nemiroff, M.D., Oradell, N. J.

ANSWER.—As a rule cerebral malaria does not occur with vivax (tertian) malaria. It is possible to have convulsions in recurrent malaria of the vivax type, with hyperthermia. It would be doubtful if the rapid death occurred as the result of the quinacrine, which probably had been taken on many previous occasions without similar effects. It would seem doubtful that this is a case of adrenal gland disease of the Waterhouse-Friderichsen type from the available evidence.

## INTRAVENOUS THIAMINE AND PYRIDOXINE

*To the Editor:—What is the maximum dose of thiamine hydrochloride and pyridoxine permitted intravenously to a female patient suffering from toxemia caused by pregnancy? A colleague has suggested 200 mg. of each at the same time. I feel that this amount would endanger the liver of the patient.*

Fred F. Prausnitz, M.D., Larchmont, N. Y.

ANSWER.—Thiamine hydrochloride can be toxic and probably not more than 50 mg. should be given intravenously. In one case 100 mg. produced complete collapse. Some authorities say that only 1 to 2 mg. is utilized daily; if this is true, large doses are unnecessary. The oral route seems to be as good as any other unless vomiting prevents it. As for pyridoxine, much less is known about it and the dosage has not been completely established.

The many preparations of vitamin B in which the various elements are given in their known amounts according to present day knowledge are much better to use orally. If the patient is vomiting, they can be given intramuscularly.

The value of using large amounts of thiamine or pyridoxine in toxemia of pregnancy has not been proved.

## TUBERCULIN SKIN TEST

*To the Editor:—How long after onset of infection does it take a patient with skin tuberculosis to acquire sensitivity (allergy) so that it can be detected by the usual tuberculin skin tests?*

Edward S. King, M.D., Winston-Salem, N. C.

ANSWER.—The most reliable data come from the vast experience of the last few years with intracutaneous injection of BCG vaccine. Since the organism used in this vaccine is a live bacillus and inoculation sets up a true, even though abortive infection, data from vaccination experiments would seem to answer the question most satisfactorily. Experience has shown that after administration of 0.1 mg. BCG vaccine, the tuberculin skin reaction becomes positive during the third week. Tests at the end of three weeks generally elicit positive reactions to 0.1 mg. old tuberculin, although the reaction is ordinarily not a strong one. Probably the results of this controlled observation in vaccinated persons can be applied in estimating the time of development of skin allergy after accidental skin infection with tubercle bacilli in man.

## HUMAN FERTILIZATION BY ANIMALS

*To the Editor:—Is there any truth to stories that women can be bred and conceive by animals? Can men breed with female animals?*

M.D., Illinois.

ANSWER.—Mating of human beings with animals is physiologically impossible; hence, there is absolutely no basis for the stories that pregnancy can result from such matings. No one has even attempted to bring forth proof of such an occurrence.

## TREATMENT OF ARTERIOSCLEROSIS

*To the Editor:—What is the present status of the use of choline and inositol in the treatment of arteriosclerosis?*

Maurice Goleburn, M.D., Wilmington, Del.

ANSWER.—Dr. Lester Morrison of the College of Medical Evangelists has reported that choline appears to have a slight favorable effect on cholesterol-induced arteriosclerosis in rabbits. No report of the use of choline in human arteriosclerosis has been found in the recent medical literature. This is also true for inositol.

The evidence for the role of cholesterol in the production of human arteriosclerosis is equivocal and there is no evidence that the feeding of choline or inositol will alter significantly the blood cholesterol levels in normal or arteriosclerotic animals or human beings.

## CHILDREN'S SHOES

*To the Editor:—At what stage should an infant wear shoes? Is there any advantage in the high shoe as compared with the oxford at any stage of development? Is there any advantage to the type of shoe in which the sole continues up the back of the shoe (Jumping Jacks) in the normally developing foot?*

Milton Marcus, M.D., New York.

ANSWER.—1. Shoes need not be put on infant's feet until they stand and walk on hard surfaces. When children start to walk and the surfaces are soft (sandpiles, grass, play pen pads) they should be allowed to walk barefoot. This will permit normal development of the foot. 2. The infant's first walking shoe should be firm soled with a rigid counter and adequate support for the arches. Most observers believe that the first shoes should be high topped, to provide ankle support. After the child has learned to walk either high shoes or oxfords are acceptable. 3. The continuation of the sole up the back merely serves as a firm counter.

## OIL-ANESTHETIC MIXTURES

*To the Editor:—Is it safe to inject one of the oil-anesthetic mixtures into the pericoccygeal tissues for relief of coccydynia? Have any of the oil-anesthetic mixtures been used for paravertebral lumbar sympathetic blocks? Are there any authentic cases on record of oil embolism (pulmonary) following the use of anesthetic-in-oil mixtures?*

Paul Russell, M.D., Inglewood, Calif.

ANSWER.—Anesthetic-in-oil mixtures are used for the relief of chronic pain. These mixtures, for the most part, contain procaine and benzyl alcohol in a peanut oil base. They are most useful when pooled about a nerve trunk. The infiltration into tissues with this material, especially if the tissue is superficial, does not seem advisable because of the danger of sloughing. Anesthetic-oil mixtures have been used for paravertebral lumbar sympathetic blocks. It would be extremely unlikely for oil embolism to occur after use of these mixtures provided the proper technic of injection is followed. One must be sure to aspirate frequently to avoid intravascular injection.

## INSULIN IN INOPERABLE CANCER

*To the Editor:—I am treating a man with inoperable carcinoma of the descending colon, who is still able to continue his business most of the time. Because of loss of weight and vomiting in the presence of minimal pain, the question has come up whether insulin for malnutrition would conceivably stimulate the progress of the tumor. Is there a contraindication to giving insulin for undernourished persons with early duodenal ulcer?*

M.D., Virginia.

ANSWER.—The use of insulin to stimulate a gain in weight has had wide favor, and at times has seemed to be effective. Insulin is not known to stimulate the growth of cancer. Insulin in small doses (5 units) may be used to stimulate the appetite of undernourished patients who have duodenal ulcer. Use of doses large enough to produce hypoglycemia should be avoided because of the stimulating effect of hypoglycemia on gastric secretion.

| | |
|---|---|
| Howard F. Root | Boston |
| Paul J. Hanzlik | San Francisco |
| Ludvig Hektoen | Chicago |
| *Urban Maes* | *New Orleans* |
| H. *J.* Corper | Denver, Colo. |
| James P. Leake | Washington, D. C. |

## SECTION OFFICERS 1949-1950

**Internal Medicine**—Chairman, Arthur L. Bloomfield, San Francisco; Vice Chairman, Ralph A. Kinsella, St. Louis; Secretary, Walter L. Palmer, 950 E. 59th Street, Chicago 37.

**Surgery, General and Abdominal**—Chairman, Michael E. DeBakey, Houston, Texas; Vice Chairman, R. Glen Spurling, Louisville, Ky.; Secretary, I. Ridgeway Trimble, 8 W. Madison St[illegible] Baltimore.

**Obstetrics and G**[illegible] ies R. Bloss, Huntington, W. Va.; Vice Chairman, Bernar[illegible] Secretary, Arthur B. Hunt, 102 Second Avenue S.W., Rochester, Minn.

**Ophthalmology**—Chairman, A. Ray Irvine, Beverly Hills, Calif.; Vice Chairman, Albert N. LeMoine, Kansas City, Mo.; Secretary, Trygve Gundersen, 101 Bay State Road, Boston 15.

**Laryngology, Otology and Rhinology**—Chairman, William H. Johnston, Santa Barbara, Calif.; Vice Chairman, Harold Hickey, Denver; Secretary, J. Milton Robb, 1553 Woodward Avenue, Detroit 26.

**Pediatrics**—Chairman, Margaret Mary *Nicholson, Washington*, D. C.; Vice Chairman, Adolph G. De Sanctis, New York; Secretary, Wyman C. C. Cole, 3001 W. Grand Boulevard, Detroit 2.

**Experimental Medicine and Therapeutics**—Chairman, McKeen Cattell, New York; Vice Chairman, James A. Greene, Houston, Texas; Secretary, Carl V. Moore, 600 S. Kingshighway *Boulevard, St. Louis.*

**Pathology and Physiology**—Chairman, F. W. Konzelmann, Atlantic City, N. J.; Vice Chairman, A. S. Giordano, South Bend, Ind.; Secretary, Edwin F. Hirsch, 1439 S. Michigan Avenue, Chicago.

**Nervous and Mental Diseases**—Chairman, Frederick P. Moersch, Rochester, Minn.; *Vice Chairman, A. E. Bennett, Berkeley,* Calif.; Secretary, Francis M. Forster, 1025 Walnut Street, Philadelphia 2.

**Dermatology and Syphilology**—Chairman, Clinton W. Lane, St. *Louis;* Vice Chairman, *Norman N. Epstein,* San Francisco; Secretary, John H. Lamb, 117 N. Broadway, Oklahoma City.

**Preventive and Industrial Medicine and Public Health**—Chairman, Carl N. Neupert, Madison, Wis.; Vice Chairman, Rutherford T. Johnstone, *Los Angeles;* Secretary, Jean S. Felton, Clinton National Laboratory, Oak Ridge, Tenn.

**Urology**—Chairman, Edward N. Cook, Rochester, Minn.; Vice Chairman, Hugh J. Jewett, Baltimore; Secretary, Earl E. Ewert, 605 Commonwealth Avenue, Boston 15.

**Orthopedic Surgery**—Chairman, Joseph S. Barr, *Boston;* Vice Chairman, Walter P. Blount, Milwaukee; Secretary, Charles N. Pease, 104 S. *Michigan Boulevard,* Chicago.

**Gastro-Enterology and Proctology**—Chairman, Russell S. Boles, Philadelphia; Vice Chairman, F. G. Runyeon, Reading, Pa; Secretary, Donovan C. Browne, 3636 St. Charles Avenue, New Orleans.

**Radiology**—Chairman, U. V. Portmann, Cleveland; Vice Chairman, J. C. Dickinson, Tampa, *Fla.; Secretary, Paul C. Hodges, 950 E. 59th Street,* Chicago.

**Anesthesiology**—Chairman, Fred W. Clement, Toledo, Ohio; Vice Chairman, Scott M. Smith, Salt Lake City, Secretary, John S. Lundy, 102 Second Avenue S.W., Rochester, Minn.

**General Practice**—Chairman, Milton B. Casebolt, Kansas City, Mo.; Vice Chairman, Lester D Bibler, Indianapolis; Secretary, Thomas E. Robinson, 1088 E. 21st South Street, Salt Lake City.

**Diseases of the Chest**—Chairman, Walter E. Vest, Huntington, W. Va.; Vice Chairman, Alvis E. Greer, Houston, Texas; Secretary, Jay A. Myers, 91 S. Seventh Street, *Minneapolis 2.*

# JOURNALS ABSTRACTED IN THE CURRENT MEDICAL LITERATURE DEPARTMENT, MAY—AUGUST 1949

Titles have been listed or abstracts made of important articles in the following journals in the Current Literature Department of THE JOURNAL during the past four months. Any of the journals, except those starred, will be lent by THE JOURNAL to subscribers in continental United States and Canada and to members of the American Medical Association for a period not exceeding three days. Three journals may be borrowed at a time. No journals are available prior to 1938. Requests for periodicals should be addressed to the Library of the American Medical Association and should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Thus most of these journals are accessible to the general practitioner.

# SUBJECT INDEX

This is an index to all the reading matter in THE JOURNAL. In the Current Medical Literature Department only the articles which have been abstracted are indexed.

The letters used to explain in which department the matter indexed appears are as follows: "BI," Bureau of Investigation; "E," Editorial; "C," Correspondence; "OS," Organization Section; "ab," abstracts; the star (*) indicates an original article in THE JOURNAL.

This is a subject index and one should, therefore, look for the subject word, with the following exceptions: "Book Notices," "Deaths," "Medicolegal Abstracts" and "Societies" are indexed under these titles at the end of the letters "B," "D," "M," and "S." Matter pertaining to the Association is indexed under "American Medical Association." The name of the author, in brackets, follows the subject entry.

For author index see page 1424.

A

- ABBOTT-Miller Tube: See Duodenal Tube
- ABDOMEN: See also Gastrointestinal Tract; Pelvis; Peritoneum
  - actinomycosis, [Campbell] 250—ab
  - Adhesions: See Adhesions, abdominal
  - Distention: See Flatulence
  - hemorrhage (intraperitoneal) and rupture of graafian follicle, [Lowen] 129—ab
  - pain, myelogenous leukemia, 1357
  - pain with hyperamylasemia first sign of pancreas cancer, [Ross] 1360—ab
  - Surgery: See also Appendectomy
  - surgery, endometriosis in, [Abel] 250—ab
  - surgery, peritoneal drainage in, [Baker] 1185—ab
  - surgery, routine appendectomy in gynecologic laparotomy, 1171
- ABEL, A. LAWRENCE, (introduction and address at Atlantic City session) 796; (elected Honorary Fellow of A. M. A.) 802
- ABEL Prize: See Prizes
- ABNORMALITIES: See also Crippled; Dwarfism; under names of specific organs as Brain; Heart
  - atomic bomb radiation and abnormal children, 377—ab
  - congenital defects after maternal rubella, [Abel & Van Dellen] ★1210
- ABORTION, in those having low level of protein-bound iodine; thyroid medication in pregnancy, (reply) [Chapman] 580
  - oliguria after, [O'Donnell] ★1201
  - therapeutic, indicated in rubella to prevent congenital defects? [Abel & Van Dellen] ★1210
- ABSCESS: See under organ affected as Brain; Lungs
  - Subphrenic: See Diaphragm
- ABSENTEEISM: See Industrial Health Workers
- ABSTRACTING: See Journals
- ACADEMY: See under names of specific academies as American Academy; National Academy; New York Academy; list of Societies at end of letter S
- ACCELERATION, use of human centrifuge in studies on headaches, [Kunkle] 914—ab
- ACCIDENTS: See also Disability; Trauma; Wounds
  - fatal, preventable, 408—E
  - Industrial: See Industrial Accidents
  - Insurance: See Insurance
  - passenger safety record for 1948, 1285
  - toxic drugs in relation to, U. of Rochester study [Gleason] 834—C
- ACID, acetylsalicylic treatment of rheumatic fever, [Roskam] 756—ab
  - acidification of tissue bordering cancers, [Black] 563—ab
  - Amino Acids: See Amino Acids
  - *p*-aminobenzoic, sodium salt of, in lupus erythematosus, 579
  - *p*-aminobenzoic, treatment of Rocky Mountain Spotted Fever, [Hooten] 1361—ab
  - [illegible] nt of tuberculosis, [illegible] [Carstensen] 436—ab
  - [illegible], 438
  - ascorbic, treatment of aniline poisoning in dye worker, [Jasinski] 756—ab
  - Bile: See Bile acid
  - boric, a poison, [Fellows] 498—ab
  - Carbolic: See Phenol
  - fatty, adding surface-active compounds to foods; Council report, 783; 786—E
  - Folic, Antagonist: See Aminopterin
  - folic, experiences with, [Waldenström] 256—ab
  - folic, N.N.R., (Eaton), 1340
  - folic, treatment of celiac disease, [Hay] 569—ab
  - folic, treatment of nervous syndrome of pernicious anemia, [Jamra] 130—ab
  - folic, treatment of pernicious anemia, relapse during, [Mollin] 255—ab
  - glutamic, effect in mongolian idiocy, [Zimmerman] 1239—ab
- ACID—Continued
  - hyaluronic, metabolism, relation to rheumatic diseases, [Cohen] 1186—ab; 1311
  - hydrofluoric, poisoning, lethal dose, 658
  - Nicotinic, Diethylamide of: See Nikethamide
  - nicotinic, in obliterating endarteritis, [Prusik] 1304—ab
  - nicotinic, transformation of tryptophane to, 876—E; 1100—E
  - succinic, stimulating respiration, [Castex] 992—ab
  - undecylenic, orally in psoriasis, [Perlman & Milberg] ★865
  - undecylenic, zincundecate, desenex, N.N.R., (description) 21; (Wallace & Tiernan) 21
- ACIDOSIS, Diabetic: See Diabetes Mellitus, acidosis
- ACNE as seen in general practice; treatment, [Fox & Shields] ★764
- ACROMEGALY, feet getting longer all the time, 850
- ACROMELALGIA: See Erythromelalgia
- ACTINOMYCES, Antibiotic Prepared from: See Streptomycin
- ACTINOMYCOSIS of thorax and abdomen, [Campbell] 250—ab
  - pathologic and bacteriologic study, [Weed] 1292—ab
- ACTIVITY following operation or illness: See Convalescence
- ADAMS, JOHN C., rear admiral retires. 484
- ADDICTION: See Alcoholism; Narcotics
- ADDISON'S ANEMIA: See Anemia, Pernicious
- ADDRESSES: See Lectures
- ADENOFIBROMAS of breast, [Saltzstein & Pollack] ★1000
- ADENOMA, Nontoxic, of Thyroid: See Goiter
  - of lung, induced by urethane in mice, [Selbie] 1300—ab
  - Toxic, of Thyroid: See Goiter, Toxic
- ADENOMYOSIS: See Endometriosis
- ADHESIONS, abdominal, and intraperitoneal penicillin, [von Rütte] 364—ab
- ADOLESCENCE, acute osteomyelitis, [Favreau] 130—ab
- ADRENALIN: See Epinephrine
- ADRENALS cortex extract, activity by oral use, 242
  - Cortex Hormone (crystalline): See Desoxycorticosterone
  - cortex, rôle in hypertension, [Sapeika] 1241—ab
  - cortex steroid (cortisone), National Academy of Sciences investigation, 1158—E
  - cortex steroid (cortisone or Compound E), [Gitman] 909—C
  - excision for arteritis, [Leger] 502—ab
  - Hormone (sympathetic): See Epinephrine
  - tumor of ovary, virilism, [Mortell] 1361—ab
  - tumors, neuroblastomas, [Tho] 845—ab
  - tumors, pheochromocytoma, benzodioxan test, effect on blood pressure, [Taliaferro & others] ★1271
  - tumors, pheochromocytoma, fundus changes with, [Bruce] 356—ab
  - tumors, pheochromocytoma, successful removal, [Forsgren] 1059—ab
  - tumors, pheochromocytoma, use of adrenolytic drug in operation, [Grimson & others] ★1273
- ADRENOLYTIC DRUG, fall in blood pressure after, [Taliaferro & others] ★1271
  - use before and during operation for pheochromocytoma, [Grimson & others] ★1273
- ADVERTISING, how and where may a doctor advertise? Norway, 554
  - of drugs, rules of A. M. A. Council, ★679
- ADVISORY Board for Medical Specialties recommendation regarding, 617; 794
- AERONAUTICS: See Aviation
- AEROSOLS: See also Penicillin treatment
  - Dwyad Portable Oxygen Unit for medication with, 1341
  - Negative Pressure Sinus Unit for medication with, 1341
  - saline, to reduce dust, [Dautrebandel] 253—ab
- AFTERBIRTH: See Placenta
- AGE, Adolescent: See Adolescence
  - middle age tuberculosis in persons over forty, 934—ab
  - middle-aged men, testosterone treatment, 438
  - of fetus in utero, estimation from roentgen examinations, 1314
  - Old Age: See Old Age
- AGGLUTINATION test vs. skin test in diagnosis of brucellosis, [Carpenter] 1290—C
- AGGLUTININS, cold, in smallpox, 580
  - hemagglutination test for diagnosis of influenzal meningitis, [Warburton] 1244—ab
  - Rh: See Rh Factor
- AGITATED Depression: See Psychosis, manic depressive
- AIR: See also Oxygen
  - disinfection by triethylene glycol, tests, [Gedda] 1365—ab
  - Dust in, as Industrial Hazard: See Pneumonoconiosis
  - Embolism: See Embolism
  - pollution, Donora disaster, 335; [Mills] 556—C; 1342—E
  - pollution, excessive deaths in Chicago from, 396—ab
  - pollution, industrial, 1342—E
  - Presence of, in Cavity: See Pneumoperitoneum; Pneumothorax
  - pressures in submarines, [Ellis] 755—ab
- AIR FORCE: See Aviation
- AIR PASSAGES: See Respiratory System
- AIRPLANES: See Aviation
- ALASKA, Medical Mission to, (air force host to 1036; doctors depart), 1162—OS
  - specificity of histoplasmin and coccidioidin in Eskimos, [Sexton] 1242—ab
- ALBUMIN in Cerebrospinal Fluid: See Cerebrospinal Fluid
  - in Urine: See Albuminuria
- ALBUMINURIA, food protein intake effect on, in nephritis, [Persike] 562—ab
  - postural proteinuria, [Bull] 434—ab
- ALCOHOLISM, alcohol intolerance sign of developing delirium tremens or Korsacow's syndrome, (reply) [Peck] 1192
  - blood alcohol content in, 132
  - clinic reopened (Portal House), Chicago, 1165
  - drinking beer cause arthritis or arthralgia? 1191
  - etiologic role in deficiency diseases, Cincinnati [Blankenhorn] ★1315
  - motivational pattern of drinking, [Riley] 500—ab
  - treatment, antabus, [Johnson] 426—C; [Martensen Larsen] 433—ab; [Bell] 1359—ab
  - treatment, Connecticut hospital for addicts, 725
  - treatment, myanesin, [Schlan & Unna] ★672
- ALESEN T-Tube, Safer Gastrectomy Operative Procedure (film review), 1177
- ALFIERI, EMILIO, death, 969
- ALIENS: See Physicians, foreign
